You should know that for a population to evolve by natural selection, some of the members of the population must possess a favorable trait and be able to pass the selected trait on to subsequent

generations of the population.

✓ Concept Check

6. **Describe** the difference between evolution and natural selection.

7. The use of antibiotics has led, over time, to antibiotic resistance among bacteria. **Identify** the process that leads to the evolution of antibiotic resistance and **describe** the process.

Module 40 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Using the mechanism of natural selection discussed in this module, **describe** how populations can evolve to become better adapted to their environments over time.

LG 40.1 Evolution explains both the diversity and unity of life.

- Species differ from one another

in many different ways. Page 562

- Species also share many traits. Page 562
- Evolution can be visualized as a branching tree, with a common root (ancestor) and living organisms at the tips of the branches. Page 563

LG 40.2 Variation in populations provides the raw material for evolution.

- Variation among species and individuals within a species results from differences in the environment, or environmental variation, as well as differences in genetic material, or genetic variation. Page 565

- Genetic variation stems from mutations, or changes in the genetic material. Page 566

LG 40.3 Natural selection results in adaptations.

- An adaptation is a close fit between a trait of an organism and the environment where the organism lives. Page 566
- Natural selection is a mechanism of evolution that leads to adaptations. Page 566
- Evolution is change in a population's genetic makeup over time. Page 567

Review Questions

1. On an evolutionary tree, a branch point, or node, represents

    A. time.
    B. present-day species.
    C. a common ancestor.
    D. a trait.

2. Which of the following domains have cells with a nucleus?

    A. Eukarya and Archaea
    B. Eukarya
    C. Archaea and Bacteria

D. Archaea

3. How many major branches are there on the evolutionary tree of life?

A. One
B. Two
C. Three
D. Six

4. The majority of branches on the tree of life represent which of the following types of organisms?

A. Mammals
B. Microorganisms
C. Plants
D. Humans

5. Which does the base, or root, of an evolutionary tree represent?

A. The common ancestor of all organisms included in the tree
B. The common ancestor of a subset of the organisms included in the tree
C. An organism that is unrelated to all other organisms included in the tree
D. An organism that is the common ancestor for organisms not included in the tree

6. Which statement is true regarding the initial work of Richard Lenski and his colleagues?

A. They demonstrated that populations of bacteria can evolve in culture.

B. They demonstrated that an individual bacterium can evolve in culture.
C. They demonstrated that bacteria from earlier and later generations use glucose similarly.
D. They demonstrated that mutations in DNA are responsible for the evolution of bacteria in culture.

7. Why are bacteria a useful model in which to study evolution?

A. Bacteria can produce large populations in a short amount of time.
B. Bacteria have a long generation time.

C. Mutations do not occur in bacterial populations.

D. Bacteria are difficult to grow in the lab.

Module 40 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

1. Identify which provides evidence that all life on Earth evolved from a common ancestor.

A. The use of specialized organelles to carry out cellular functions
B. The use of the same set of amino acids to build proteins
C. The diversity of metabolic pathways used by organisms in different environments
D. The presence of a nucleus in eukaryotic cells

2. Which illustrates an evolutionary process in action?

A. The fur on an individual snowshoe hare turns from brown to white in the winter.
B. Bacterial cells activate specific metabolic pathways in response to the availability of a

nutrient.

C. Within a single species of bacteria, only cells that are genetically resistant to an environmental toxin survive and reproduce when the toxin is present.

D. Recessive traits “skip” generations, reappearing in the offspring of two individuals who carry the recessive genes for the trait.

3. Which is required for long-term evolution by natural selection?

A. Phenotypes must be influenced by the environment.

B. Environmental conditions

must rapidly change.

C. Offspring must inherit phenotypes from their parents.

D. Mutation must create new genetic variation every generation.

4. Cats such as lions, tigers, and even house cats are extremely capable hunters. A key trait that enables cats to hunt successfully is their sharp claws, which can be contrasted to the blunt claws of dogs or the flat fingernails of humans. Which statement best explains the evolution of sharp claws in the cat family?

A. The ancestors of modern cats evolved sharp claws because

they needed them to hunt and survive.

B. The ancestors of cats hunted prey that also had sharp claws, so the cats evolved sharp claws in response.

C. The ancestors of cats that had sharper claws were more successful at hunting and had more offspring.

D. The ancestors of cats that had sharper claws had lower evolutionary fitness and were eliminated by natural selection.

Section 2: Free-Response Question

Write your answer to each part

clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Natural selection is one of the primary mechanisms by which biological evolution occurs and is central to the generation of Earth's biological diversity.

a. **Identify** the ultimate source of all variation on which evolution acts.
b. Both genotype and environment can generate phenotypic variation among individuals in a population. A scientist claims that evolution by natural selection occurs when phenotypic variation in a trait is determined by genetic

variation in a population, but variation in a trait due to differences in environment cannot result in evolution. **Provide reasoning** to support or refute the claim.

Module 41

Natural and Artificial Selection

LEARNING GOALS

- **LG 41.1 Natural selection brings about adaptations and increases fitness.**
- **LG 41.2 Natural selection acts on phenotypes.**
- **LG 41.3 Artificial selection has produced many different breeds of plants and animals.**
- **LG 41.4 Sexual selection increases an individual's ability to find and**

attract mates.

In Modules 0 and 40, we introduced the concept of evolution, or change over time. Specifically, evolution is a change in the genetic makeup of a population from generation to generation. As we discussed in Unit 5, the genotype of an organism can affect its phenotype, or outward appearance. Phenotypic variation in a population is important because, in some cases, the phenotype affects the ability of an organism to survive or reproduce in a particular environment. Those that survive and reproduce more than others will pass on their traits to the next generation, and the population will change over

time. Charles Darwin recognized that this process, which he called natural selection, provides a mechanism of evolutionary change over time. Natural selection not only leads to changes in populations over time but also brings about adaptations, the close fit between an organism and its environment. And just as populations change over time, so does the environment. So, evolution is an ongoing process that began with the first cell and continues today.

In this module, we will take a closer look at natural selection and how it brings about adaptations. We will also look at different types of selection and the effect they have on

phenotypes of organisms that make up a population. Even before Darwin proposed his theory of evolution by natural selection, humans understood that they could modify breeds of animals and plants through selective breeding, which we will also discuss. Finally, we will look at a form of selection that is responsible for many of the bright colors and displays among birds and other animals.

41.1 Natural selection brings about adaptations and increases fitness

A conspicuous aspect of the natural world is that organisms are well

adapted to the environment in which they live. Charles Darwin proposed his theory of evolution by natural selection to explain how these adaptations come about. He suggested that organisms change over time, and that this change is not random. Instead, organisms that are well suited to a particular environment leave more offspring than those that are less suited to that environment. The result is that populations change and become adapted to their environment over time. In this section, we will describe many examples of adaptations, and then look closely at how Darwin proposed they come about.

Adaptations

Organisms are often exquisitely adapted to their environments. Think of an eagle, pictured in **FIGURE 41.1**. Everything about this animal tells you it's a predator—the powerful wings; strong beak; keen sense of vision; and sharp, hooked claws called talons. In fact, if you didn't know that an eagle is a predator, you could probably figure it out just by looking at the photograph. All of these traits are examples of adaptations.

FIGURE 41.1 Adaptations

Eagles have many adaptations for hunting, such as a strong wings and powerful claws.

Adaptations are commonplace in nature. Your eyes are well adapted for seeing; your hands for grasping; your legs for walking. Desert plants are adapted for a dry, hot environment: they resist drying out, or desiccation. Other plants are adapted for growing in full sunlight or deep shade. The burs of plants are adapted to catch on to the fur of a passing animal, helping to disperse their seeds. Sharks have muscular fins, sharp teeth, powerful jaws, a keen sense of smell, and large eyes facing forward. Some bacteria are well adapted to live in what we call extreme environments, such as high salt, low pH, or high temperatures that are lethal to many other types of organisms.

For thousands of years, people have been struck by these and other adaptations. The fit is sometimes so close and so wonderful that many people have asked why organisms are so well adapted. How did they get this way? How did the woodpecker get its powerful chisel of a bill? And the hummingbird its long delicate bill for probing nectar in flowers? Charles Darwin, pictured in **FIGURE 41.2**, came up with an elegant answer to these questions. First, he suggested that species are not unchanging, but rather have evolved over time. Second, he proposed a mechanism, natural selection, that brings about adaptations. Natural selection is a brilliant solution to the central

problem of biology: how organisms come to fit so well in their environments. Darwin showed how a simple mechanism leads to an extraordinary range of adaptations.

FIGURE 41.2 Charles Darwin

This portrait shows Darwin just after he returned from his five-year voyage around the world as a naturalist on board the HMS *Beagle*.

How did Darwin come up with his revolutionary idea? He famously sailed around the world as a naturalist on board the HMS *Beagle* in the 1830s. During this voyage, he saw species that he had never seen before on Pacific islands like the Galápagos and in rainforests in South America

and Southeast Asia. He was also struck by fossil organisms—the remains of species that lived long ago but are now extinct. He collected beetle specimens and spent many years studying barnacles. He raised pigeons and bred them, seeing if he could favor certain traits over others.

For 20 years after first conceiving the essence of his theory, Darwin collected supporting evidence for that theory. In 1858, he was finally spurred to publish his ideas by a letter he received from another naturalist named Alfred Russel Wallace, who is pictured in **FIGURE 41.3**. By a remarkable coincidence, Wallace had independently come up with the

theory of evolution by natural selection. Aware that Darwin was interested in the problem but having no idea that Darwin was working on the same theory, Wallace wrote to Darwin to ask what Darwin thought of his idea.

FIGURE 41.3 Alfred Russel Wallace

This portrait shows Wallace collecting and describing specimens in the tropics, where he spent many years.

Suddenly, Darwin was confronted with the prospect of losing his claim on the theory that he had been nurturing for 20 years. But all was not lost. Darwin's colleagues arranged for the publication of a joint paper by Wallace and Darwin in 1858. Then,

one year later in 1859, Darwin published *On the Origin of Species*. It was this work that brought both evolution and natural selection, its underlying mechanism of adaptation, to public attention.

Darwin's Postulates

Darwin's theory of evolution by natural selection is a simple idea with profound implications. It rests on certain observations or claims that are sometimes called Darwin's postulates. Although he didn't use that term, he did describe them in the introduction of *On the Origin of Species*.

The first postulate is that the

members of a species vary from one another, a point we highlighted in the previous module. This may seem obvious to you. A walk down any street reveals how variable our species is: skin color and hair color, for example, are different from person to person, as can be seen in **FIGURE 41.4**. However, until the publication of *On the Origin of Species,* naturalists tended to view all the variation we see in humans and other species as biologically unimportant. Darwin drew our attention to the variation that we see all around us and suggested that it is key to understanding how species evolve.

FIGURE 41.4 Human variation

Darwin's first postulate states that individuals of a species look different from one another.

Note that when we talk about variation in appearance, we are referring to variation in phenotype. As we saw in Unit 5, phenotype is an observable trait, such as human height or butterfly wing color. Two factors contribute to phenotype: an individual's genotype (genetic makeup) and the environment in which the individual lives. For example, human height is influenced by thousands of genes, as well as by nutrition during fetal development and childhood. Phenotypic variation, or variation in appearance, is the

result of genetic variation and environmental variation.

The second postulate, already noted in Unit 5, is that some phenotypic variation is heritable, or passed on to the next generation. We know this from common experience—tall parents tend to have tall children, for example. And humans have used this knowledge to select traits in breeds of farm animals and crops for thousands of years. The phrase “like begets like” nicely captures this well-known and well-accepted observation.

The third postulate is that in nature, organisms frequently compete for resources. Populations tend to grow

rapidly, but the resources on which they depend, such as food, water, and living space, do not. Some individuals are more successful in this competition because of certain traits; as a result of the variation among individuals, some are more likely to survive and reproduce than others.

Both Darwin and Wallace came across this idea when reading the writings of a British clergyman, Thomas Robert Malthus. In his *An Essay on the Principle of Population*, Malthus pointed out that populations have the potential to increase in size extremely rapidly. For example, imagine a sexually reproducing group of organisms in which each pair has

four offspring, two males and two females. If reproduction continues, so that each pair has four offspring, the population will double in size every generation. Starting with a single pair, the population will have grown to more than a million by the 20th generation. In reality, this rapid expansion of populations does not typically occur. In fact, many population sizes are often stable from generation to generation, largely because the resources upon which populations depend are limited. In each generation, many individuals fail to survive or reproduce. There are not enough resources to go around, so individuals in a population often compete with one another, and some

variants are more successful than others.

The fourth postulate is that variations that increase survival and reproduction will be passed on to individuals in the next generation. Individuals with variations that are best suited to the environment will tend to survive more and leave more offspring, so that the particular beneficial trait or variant will be more common in the next generation. For example, a desert plant, such as the cactus pictured in **FIGURE 41.5**, that is a little better at minimizing water loss will pass this trait to its offspring. Offspring with this trait will be more likely to survive and reproduce in the

desert climate. The next generation will therefore have a higher proportion of cacti with this beneficial trait. Note that the genetic makeup of the population will now be different from the previous, ancestral population. Darwin used the term "natural selection" for the filtering process that acts in favor of beneficial traits and against harmful traits. Specifically, natural selection is the differential reproductive success of genetic variants.

FIGURE 41.5 A desert plant adapted for a dry climate

This saguaro cactus is well adapted to the desert because it minimizes water loss. For example, it has spines rather

than leaves to reduce the surface area available for evaporation.

The claims of Darwin's four postulates are powerful because they are simple and testable. In addition, they lead to two conclusions. The first is that populations will change over time, or evolve, because in each generation the variants that leave more offspring will be overrepresented and the variants that leave fewer offspring will be underrepresented. The second is that organisms will become adapted to their environment over time because those that do survive and reproduce are not random, but those best suited to the environment

in which they live.

AP® EXAM TIP

PREP FOR THE AP® EXAM

Make sure you have a clear understanding of Darwin's postulates. You should be able to state the postulates in your own words and provide an example of each.

Fitness

Competitive advantage is a function of how well an organism is adapted to its environment. An organism that is better adapted to its environment is more fit. Fitness is a measure of the ability of an individual to survive and

reproduce in a particular environment. More specifically, it is the extent to which the individual's genotype is represented in the next generation.

A desert plant is more efficient at minimizing water loss than other plants and is therefore better adapted to the desert environment. We say that the one plant's fitness is higher than another plant's fitness if one is more likely to survive or leaves more offspring than another plant. One type of plant could leave more offspring because it survives longer, which gives it more opportunities to reproduce, or because it has some other reproductive advantage, such as

the ability to produce more seeds. Note that fitness is relative, meaning that it only makes sense to talk about the fitness of one organism in relation to the fitness of another. Fitness describes how well an individual survives and reproduces compared to other individuals of the same species.

The words “fit” and “fitness” therefore have different meanings in evolutionary biology than they do in everyday language. In common usage, being fit has to do with working out and being healthy. In evolution, however, the meaning is quite different: being fit is the ability of an individual to survive and reproduce in the environment in which it lives.

Assuming that a trait—for example, the ability to minimize water loss—remains advantageous in a particular environment, natural selection acts over generations to increase the overall fitness of a population. A plant newly arrived in a desert may be poorly adapted to its environment. Over time, however, traits that minimize water loss increase under natural selection, resulting in a population of plants that is better adapted to the desert environment. So, although natural selection acts on individuals, it is populations, not individuals, that evolve over time.

Such changes in populations often take a long time. Darwin, borrowing

from the geologists of his day, recognized that time was a critical ingredient of his theory. Geologists had put forward a view of Earth's history that argued large geological changes—like the carving of the Grand Canyon—can be explained by simple, day-to-day processes operating over vast timescales of thousands, millions, or even billions of years. Darwin applied this view to biology. He recognized that small changes can add up to major changes over long time periods. What might seem to be a trivial change over the short term can, over the long term, result in substantial differences among populations, eventually leading to the origin of new species

and the remarkable diversity of living organisms we see today.

Role of the Environment

A key point about fitness is that it depends on the environment in which an organism lives. A trait that is well suited to one environment may not be well suited to another. This is particularly important in the face of a changing environment. As an environment changes, an organism that was more fit may become less fit, and the other way around. For example, a desert plant that is well adapted to the dry, arid environment of a desert will be less well adapted if

it is moved to a wet, humid environment. Changes in the environment might be natural, such as the changes in a forest ecosystem over time, or they might be caused by human activity, such as the introduction of a non-native species to an area or the use of pesticides and herbicides.

Biologists use the term **selective pressure** to describe the full set of environmental conditions, both biotic (biological factors such as other organisms) and abiotic (physical factors such as air, soil, and water), that allow some organisms to survive and reproduce better than others. In a constant environment, selective

pressures tend to be stable. In the face of an environmental disturbance, whether natural or caused by humans, selective pressures can change. The term is useful because it draws attention to the role of the environment in influencing how natural selection acts on a population. Note that natural selection is not a forward-looking process and cannot anticipate environmental conditions that might occur in the future. Natural selection acts on populations with respect to current environmental conditions. In a similar way, natural selection does not have a goal or endpoint in mind.

Fitness depends on the environment.

Therefore, to understand the fitness of different organisms we need to know something about the environment in which they live. Let's consider two types of bacteria, and ask the following question: which is more fit, antibiotic-sensitive bacteria or antibiotic-resistant bacteria? While it's tempting to think that antibiotic-resistant bacteria are more fit because, after all, they are able survive and reproduce in the presence of antibiotics, the fact is that we don't know which is more fit because we didn't describe the environment in which the bacteria are living.

In the presence of antibiotics, we can

answer the question: the antibiotic-resistant bacteria are more fit because they will survive better and reproduce more quickly than the antibiotic-sensitive bacteria. The antibiotic-resistant bacteria will pass on this trait to their offspring, and the population will evolve antibiotic resistance over time.

What about in the absence of antibiotics? In this case, you might think that the two strains of bacteria are equally fit. After all, without antibiotics in the environment, it might seem that it doesn't matter whether bacteria are antibiotic sensitive or resistant. But, in this case, antibiotic-sensitive bacteria

typically outcompete antibiotic-resistant bacteria because it takes energy to be antibiotic resistant, and this energy can't be used for other essential functions, like survival and reproduction.

✓ Concept Check

1. **Describe** three adaptations displayed by organisms.

2. **Identify** Darwin's four postulates.

3. **Describe** fitness.

4. **Describe** one example of how you might measure fitness of individuals in a population.

41.2 Natural selection acts on

phenotypes

When we consider interactions of organisms and their environments, we are focusing on the traits of organisms—the shape of a bird's beak, or drought tolerance in a desert plant, or the streamlined body of a fish. These are all examples of phenotypes, the outward appearance of an organism. Natural selection acts on phenotypes. In a particular environment, certain traits are beneficial and individuals with those traits tend to survive and reproduce more than others. These traits then become more common in succeeding generations until they spread to the entire population. Other traits may be

harmful and therefore individuals with these traits leave fewer offspring, making these traits less common in future generations. In this section, we will focus on the effect of natural selection on phenotypes of organisms.

Phenotypic Change

The effect that natural selection has on phenotypes is well illustrated when different species are placed in similar environments. In this situation, they tend to converge on similar phenotypes. For example, sharks have a streamlined shape, which is an adaptation for swimming in water. Marine mammals, such as

whales and dolphins, evolved from four-legged, land-based animals that returned to the water. Over time, they became adapted to moving around in the water, so ended up with a similar streamlined shape. **FIGURE 41.6** shows the uncanny resemblance between a shark and dolphin, even though many of their traits evolved independently of each other. The similarities between sharks and dolphins is an example of **convergent evolution**, a process by which two different species evolve similar traits in response to similar selective pressures, in this case, moving efficiently in an aquatic environment.

FIGURE 41.6 Convergent evolution

Dolphins (top) and sharks (bottom) closely resemble each other because they are both adapted to swim in the water. The process by which two species independently develop similar traits under similar selective pressures is called convergent evolution.

Phenotype, as we have seen, depends in part on the underlying genotype. Weight, for example, depends on the genetic makeup of an individual, as well as such factors as diet and exercise. Even though natural selection acts on phenotypes, it is genotypes that are passed on to the next generation. In this way, the genetic makeup of a population

changes over time.

The genetic variation that gives rise to phenotypic differences is ultimately the result of mutations. Although we all have the same set of genes, we have different versions or forms of those genes. As we saw in Unit 5, alleles are different forms of a particular gene. The different alleles of a gene are the result of mutations. When we talk about a beneficial mutation, we mean that it results in a phenotype that is beneficial to an individual in a given environment. The individual with this trait will tend to survive and reproduce more, and therefore that phenotype and the underlying genetic mutation will be

more represented in the next generation. Conversely, a harmful mutation confers a phenotype that results in an individual with a reduced ability to survive or reproduce. This individual is therefore less fit in this environment.

Natural selection increases the frequency of beneficial alleles, resulting in adaptation. To start with, a new beneficial allele will exist as a single copy in a single individual. Subsequently, under the influence of natural selection, the beneficial allele will increase in frequency over time and may replace all the other alleles in the population. In some cases, natural selection increases the

frequency of a beneficial allele until the population is fixed for the allele, which means all the individuals in the population have the allele. By contrast, a harmful allele will become less common over time, until it is eliminated from the population.

In short, natural selection results in the frequency of alleles changing from generation to generation according to the allele's impact on the survival and reproduction of individuals. New mutations that are harmful and eliminated by natural selection have no long-term evolutionary impact. Neutral mutations do not affect survival and reproduction and therefore do not

affect fitness and are not acted on by natural selection. In contrast, mutations that are beneficial become more common and result in adaptation to the environment over time.

Stabilizing, Directional, and Disruptive Selection

Because natural selection acts on phenotypes, we can follow the effects of natural selection by looking at changes over time in a particular trait of an organism. For example, we might track the evolution of height in a population, despite not knowing the specifics of the genetic basis of height

differences. When we look at natural selection from this perspective, we see three patterns: stabilizing, directional, and disruptive.

Stabilizing selection maintains the status quo and acts against extremes. Human birth weight is a good example. The trait of human birth weight is affected by a number of factors, including many fetal genes and the environment. If a baby is very small, its chances of survival at birth are low. However, if it is very large, there may be complications during delivery that endanger both mother and baby. The optimal birth weight is intermediate, somewhere between these two extremes. In this case,

natural selection acts against the extremes.

In **FIGURE 41.7**, we see a graph of human birth weight. Birth weight is plotted along the *x*-axis, from 0 to 5 kilograms (kg). Percent of population is indicated along the left-side *y*-axis. The blue bell-shaped curve, with its peak around 3 kg, indicates that most newborns weigh around 3 kg, with fewer weighing less (1–2 kg) or more (4–5 kg). The figure also plots mortality, indicated by the red dots and measured along the right-side *y*-axis. As you can see, mortality is higher for low-birth-weight and high-birth-weight babies, but lower for babies of intermediate weight.

FIGURE 41.7 Stabilizing selection

Stabilizing selection acts against extreme phenotypes and favors intermediates phenotypes. Birth weight provides an example. Mortality, indicated by the red dots, is higher for very small babies and very large babies compared to intermediate-sized babies. The result is that most babies are born at an intermediate size, indicated by the blue line. Although modern medicine has improved the survival rate of low-birth-weight babies since this study was done, the overall trend that we see in the graph still holds.

Data from Cavalli-Sforza, L. L. and W. F. Bodmer. 1971. *The Genetics of Human Populations*. San Francisco, CA: W.H. Freeman, p. 613.

The vast majority of natural selection is stabilizing; harmful mutations that cause a departure from an intermediate phenotype are selected against. These are the basis for adaptations and tend to occur in environments that are relatively stable.

While stabilizing selection keeps a trait the same over time, directional selection leads to a change in a trait in a population over time. The color forms of the peppered moth (*Biston betularia*) provide a classic example of directional selection. The moth comes in two distinct forms: a light

one, *typica,* and a dark one, *carbonaria.* The difference is determined by two alleles at a single gene, with the *carbonaria* allele dominant to the *typica* one. The *carbonaria* form is absent from collections of moths from the United Kingdom until around 1850, when its frequency started to increase in urban areas. By about 1900, *typica* had disappeared from these populations.

This striking shift is attributable to pollution caused by industry. Soot darkens trees and sulphur dioxide in smoke kills the lichens against which the *typica* form is camouflaged. With industrialization, *typica* went from being camouflaged, and therefore

protected against bird predation, to readily visible; during this same time, *carbonaria* went from being easily seen to camouflaged, as shown in **FIGURE 41.8a**. Selection therefore strongly favored the *carbonaria* allele. With anti-pollution legislation in the 1950s, however, lichen returned to trees in urban areas, and the direction of selection flipped, with *typica* now favored over *carbonaria*. Today, the *carbonaria* allele is once again extremely rare. Over the past 170 years, directional selection on these moth populations has operated strongly at different times in two different directions.

FIGURE 41.8 Directional selection

Directional selection results in a change in phenotype over time, as illustrated by the peppered moth. (a) The two color forms of the moth are shown against two different backgrounds. On a tree with lichen shown on the left, the light form (*typica*) is camouflaged and the dark form (*carbonaria*) is visible. Industrial pollution kills lichen and darkens trees, shown on the right, making the light form visible and the dark form camouflaged. (b) The graph plots the frequency of the *carbonaria* form of the moth over time in Manchester, an industrial town in north England. The frequency increased as trees became darker, providing an example of directional selection. The frequency decreased as the trees

became lighter, providing another example of directional selection.

Data from Hof, A., P. Campagne, D. Rigden, et al. 2016. “The industrial melanism mutation in British peppered moths is a transposable element,” Extended Data Figure 4: The Rise and Fall of *Carbonaria* in the Manchester Area. *Nature* 534:102–105.

Figure 41.8b shows what happened in graph form. In the graph, time is plotted on the *x*-axis and the frequency of the *carbonaria* form is plotted on the *y*-axis. As you can see, the frequency of *carbonaria* increased from 1850 to 1900, from 0 to almost 1, when it leveled off. It then decreased again from about 1950 to the present.

Directional selection tends to occur when the environment changes, such as increasing or decreasing pollution in the case of the peppered moth. As the environment changes, selective pressure pushes certain traits in organisms in one direction or another, such as toward darker forms or lighter forms of the moth over time.

A third mode of selection, known as disruptive selection, operates in favor of extremes and against intermediate phenotypes. Apple maggot flies of North America (*Rhagotletis pomonella*), shown in **FIGURE 41.9a**, provide an example. The larvae of these flies originally fed on the fruit

of hawthorn trees that bloom and produce fruit late in the summer. However, since the introduction of apples from Europe about 150 years ago, some apple maggot flies have evolved to eat apples that flower and produce fruit earlier in the summer. Disruptive selection has led to the evolution of two genetically distinct groups of flies, one that feeds on apples earlier and the other on hawthorn fruit later. Disruptive selection acts against intermediates between the two groups, which would miss the peaks of both the apple and hawthorn seasons.

FIGURE 41.9 Disruptive selection

Disruptive selection operates in favor of

extremes. (a) An apple maggot fly feeds on an apple. (b) Before the introduction of apple trees, all apple maggot fly life cycles were coordinated with hawthorn trees. Disruptive selection and differences in the timing of fruiting have created two peaks in the distribution—one for apple-specializing flies and one for hawthorn-specializing flies. Each population is coordinated with the fruiting time of its host tree species.

Data from Filchak et al. 2000. “Natural Selection and sympatric divergence in the apple maggot Rhagoletis pomonella,” *Nature* 407:739–742.

Figure 41.9b illustrates the process of disruptive selection. The x-axis shows

time, from mid-June to mid-October. The *y*-axis shows percent of larvae feeding on the two trees. Purple indicates apple trees and blue indicates hawthorn trees. Notice the two peaks, which show that larvae feed on apple trees earlier in the summer and on hawthorn trees later in the summer. For these flies, there is selection on the genes that influence the timing of larval feeding, in favor of feeding early or late, but not at intermediate times when neither tree bears fruit. As we will discuss in Module 47, this pattern of selection can lead to the evolution of new species, as the two populations become more and more different from one another over time.

✓ Concept Check

5. Birds and bats both have wings but evolved them independently of each other. **Identify** the term that describes the acquisition of similar structures or traits by two different groups independently of one another.

6. **Describe** how natural selection affects the frequency of beneficial and harmful alleles in a population over time.

7. **Describe** stabilizing selection and provide an example.

8. **Describe** directional selection and provide an example.

9. **Describe** disruptive selection and

provide an example.

41.3 Artificial selection has produced many different breeds of

plants and animals

Selection has been practiced by humans since at least the dawn of agriculture. We have bred many different types of livestock and crops, shaping them over time so they exhibit traits we find useful. For example, we have selected for corn with bigger kernels, cows that produce more milk, chickens that lay larger eggs, horses that run more quickly, wheat that produces a lot of grain, and so on. In each case, the breeder notices variation in a trait—such as running speed in horses—and then only allows the fastest runners to mate and have offspring. This process, played out over many

generations, has led to faster and faster horses. The process by which humans select for traits is known as **artificial selection**.

Many people are familiar with different breeds of dogs. All of these have been shaped by humans over thousands of years, making them strikingly different from one another and from their common ancestor. The different breeds of dogs demonstrate the power of artificial selection. Darwin himself was interested in this process but didn't breed dogs or cats. Instead, he chose to work with pigeons. Pigeon breeding was common in the 1800s, and breeders have selected for all kinds of traits—

larger tail feathers, fancier plumage, and different color patterns, to name a few. Today, there are hundreds of different breeds of pigeons, some of which are shown in **FIGURE 41.10**. Yet, as Darwin points out in *The Origin,* all these different breeds have a common ancestor—the rock pigeon, pictured in Figure 41.10d.

FIGURE 41.10 Artificial selection

Artificial selection has produced a remarkable variety and number of pigeon breeds, including the (a) Pygmy Pouter, (b) Old Dutch Capuchine, and (c) Blue Grizzle Frillback. All are descended from the (d) Rock Pigeon.

As Darwin himself noted, artificial selection is analogous to natural selection, but the competitive element is removed. Successful phenotypes are selected by the breeder, not through competition. Because it can be carefully controlled by the breeder, artificial selection is astonishingly efficient at generating change in populations. When practiced over many generations, artificial selection can create a population in which the selected phenotype is quite different from that of the starting population.

Although there are many similarities between artificial selection and natural selection, there is an

important difference: in artificial selection, the breeder typically has some sort of goal in mind, such as breeding faster racehorses. In natural selection, however, there is no goal or endpoint. Those that survive and reproduce are simply better adapted to the current environment.

"Practicing Science 41.1: How far can artificial selection be taken?" shows the result of artificial selection for oil content in kernels of corn. In this experiment, researchers selected for corn that has high oil content, shown in red in the graph, and separately selected for corn that has low oil content, shown in blue in the graph on page 582. Over time, the line of

corn that was selected for high oil content steadily increased in oil content, while the line that was selected for low oil content steadily decreased in oil content.

Practicing Science 41.1

How far can artificial selection be taken?

PREP FOR THE AP® EXAM

Background From the 1890s to the present day, an experiment at the University of Illinois has attempted to manipulate the properties of corn. This experiment has become one of the longest-running biological experiments in history.

Hypothesis Researchers hypothesized that there is a limit to the extent to which a population can respond to continued directional selection.

Experiment Corn was artificially selected for either high oil content or low oil content. Every generation, researchers bred together just the plants that produced corn with the highest oil content and did the same for the plants that produced corn with the lowest oil content. Each generation, kernels showed a range of oil levels, but only the 12 kernels with the highest or the lowest oil content were used for the next generation.

Results The following graph shows the results of the experiment. The percent oil content is indicated on the *y*-axis, and

the time in generations is indicated on the *x*-axis. In the line selected for high oil content, shown in red, the percentage of oil more than quadrupled, from about 5% to more than 20%. In the line selected for low oil content, shown in blue, the oil content fell so close to zero that it could no longer be measured accurately, and the selection was terminated. Both selected lines are completely outside the range of any phenotype observed at the beginning of the experiment.

Follow-up Work Genetic analysis of the selected lines indicates that the differences in oil content are due to the effects of at least 50 genes.

41.4 Sexual selection increases an individual's ability to find and attract mates

Initially, Darwin was puzzled by certain traits of organisms, such as the tail of a peacock or the bright, showy colors of many birds. These traits seem to reduce an individual's chances of survival. How then did they evolve over time? In a letter dated a few months after the publication of *The Origin,* Darwin wrote, "The sight of a feather in a

peacock's tail, whenever I gaze at it, makes me sick!" The tail is energetically expensive to produce; it is an advertisement to potential predators; and it is a hindrance to any attempt to escape a predator.

In his 1871 book, *The Descent of Man, and Selection in Relation to Sex,* Darwin proposed a solution to this problem. Natural selection indeed acts to reduce the size and showiness of the peacock's tail, but another form of selection, *sexual selection,* acts in the opposite direction. **Sexual selection** is a form of selection that promotes traits that increase an individual's ability to find and attract mates. That is, large, showy tails in male peacocks

increase their chances of attracting females, so that trait is passed on to the next generation.

Darwin recognized that this process can play out in two different ways. In one form of sexual selection, members of one sex, usually the males, compete with one another for access to the other sex, usually the females. Because competition typically occurs among males, it is in males that we often see physical traits such as large size, horns, and other elaborate weaponry. Larger, more powerful males tend to win more fights, hold larger territories, and have access to more females. When sexual selection focuses on

interactions between individuals of one sex, it is called intrasexual selection (*intra* means "within"). One example of intrasexual selection can be seen in the horns of male elks (*Cervus canadensis*) shown in **FIGURE 41.11a**.

FIGURE 41.11 Sexual selection

There are two types of sexual selection. (a) Intrasexual selection often involves competition between males, as in this battle between two male elk. (b) Intersexual selection often involves bright colors and displays by males to attract females, as shown by these Japanese red-crowned cranes, one male and one female.

Darwin also recognized a second

form of sexual selection. In this case, males typically do not fight with one another, but instead compete for the attention of females with bright colors, songs, or other advertisement displays. This form of selection is called intersexual selection because it focuses on interactions between males and females (*inter* means "between"). Intersexual selection can be seen in Japanese red-crowned cranes (*Grus japonensis*), like those shown in Figure 41.11b where a male is doing an elaborate courtship dance to attract a female.

The peacock's tail is also thought to be the product of intersexual selection: its evolution has been driven by a

female preference for ever-showier tails in males. In the absence of sexual selection, natural selection would act to minimize the size of the peacock's tail. Presumably, the peacock tails we see today are a compromise, a trade-off between the conflicting demands of attracting a mate and survival.

✓ Concept Check

13. Sexual selection tends to cause bigger size, more elaborate weaponry, or brighter colors in males. **Identify** the pattern of selection that is observed (stabilizing, directional, or disruptive).

14. **Describe** the difference between intrasexual selection and intersexual

selection.

Review Questions

1. Which of the following may be a characteristic of a beneficial mutation?

A. It facilitates successful

reproduction.

B. It decreases lifetime reproductive output.

C. It has no effect on phenotype.

D. It decreases an organism's fitness.

2. Which of the following is a source of genetic variation?

A. Adaptation

B. Natural selection

C. Convergent evolution

D. Mutation

3. Which of the following is considered a beneficial mutation?

A. A mutation that makes an individual more visible to predators

B. A mutation that increases an organism's ability to find food
C. A mutation that decreases the offspring's chance of survival
D. A mutation that changes hair color in humans

4. Which of the following is an example of stabilizing selection?

A. Selection for average birth weight in humans
B. Selection for antibiotic resistance in bacteria
C. A decrease in the number of birds that have intermediate-sized beaks in an environment with large or small seeds
D. Breeding dogs from wolves

5. What is a key difference between natural selection and artificial selection?

A. Natural selection results in evolution; artificial selection does not.
B. Artificial selection is driven by humans.
C. Natural selection may select traits that are detrimental.
D. Natural selection is controlled.

6. Which form of selection works on the ability to attract mates, even if the traits selected for reduce the organism's chance of survival?

A. Sexual
B. Asexual

C. Disruptive

D. Stabilizing

Module 41 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

1. Which provides the most direct estimate of evolutionary fitness?

   A. The birth weight of a human baby

   B. The volume of water lost by a

desert plant over the course of a day

C. The swimming speed of a great white shark

D. The number of offspring produced by a seed-eating finch

2. Which figure best illustrates disruptive selection?

A. a

B. b

C. c

D. d

Questions 3 and 4 refer to the following information:

Cardinals are small songbirds that live in the northeastern United States. Male cardinals have bright red feathers, which makes them extremely visible during breeding season. Female cardinals have duller gray or brown feathers. Males with the brightest red color are most attractive to females and have the highest reproductive success. The red

color of male cardinals is generated from carotenoid pigments obtained from the diet. The male cardinal produces enzymes that convert carotenoid pigments in the diet to the bright red pigment displayed in the feathers.

A scientist captured 16 male cardinals from a wild population and used a tool called a spectrophotometer to measure the percentage of pure red in the feathers. The scientist also measured the percentage of pure red in a sample of 10 male cardinals reared in captivity. The data obtained are shown in the following histogram. Error bars are calculated as ±1 standard deviation on either side of

the mean.

Data from McGraw, K. J., Hill, G. E. (2001). “Carotenoid access and intraspecific variation in plumage pigmentation in male American Goldfinches (*Carduelis tristis*) and Northern Cardinals (*Cardinalis cardinalis*),” *Functional Ecology*, 20 December, 2001 vol 15, issue 6, 732–739.

1. What is the difference in mean percentage of pure red color in feathers between the cardinals captured in the wild versus those reared in captivity?

   A. 76.7%
   B. 25.3%
   C. 51.4%
   D. 65.1%

2. Lutein is a pigment that is commonly found in plant seeds. Male cardinals produce an enzyme that converts lutein to α-(alpha-)doradexanthin, which is one of the four red pigments in the feathers of red cardinals. Predict the impact of a nonsense mutation in the gene encoding this enzyme on the fitness of a male cardinal.

   A. There would be no effect on fitness on the male cardinal because the enzyme is not essential for life.
   B. The male cardinal would have higher fitness because lutein is toxic and it would accumulate in the feathers.

C. The male cardinal would have lower fitness because it would be less attractive to female cardinals.
D. The male cardinal would have lower fitness because it would be less visible to predators.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Sexual selection often results in exaggerated traits in male animals such as large and flashy tails in

peacocks, large antlers in elk, and conspicuous courtship displays. The traits are often most attractive to females when they are most extreme.

a. **Identify** two reasons natural selection may act against sexually selected traits.
b. **Make a claim** about whether it is possible for a trait to be under both intersexual selection and intrasexual selection at the same time. **Justify** your response.

Module 42

Population Genetics

LEARNING GOALS

- **LG 42.1 Variation is a notable feature of the natural world.**
- **LG 42.2 Mutation and recombination are the two sources of genetic variation.**
- **LG 42.3 Genetic variation is measured by allele frequencies.**

In the last module, we focused on Charles Darwin's theory of evolution by natural selection. Natural selection

is a mechanism of evolution that leads to adaptations—the remarkable fit that organisms often have with the environment in which they live. Darwin made four claims about the natural world, which are known as Darwin's postulates. The first one is that individuals of a species are variable.

Before Darwin, these variations were largely ignored and naturalists focused instead on ideal forms or types that defined a group. Since Darwin, however, we have learned that a species consists of individuals that vary one to the next. In our own species, we can observe that people may be tall, short, dark-haired, fair-

haired, and so on. In fact, variation is an essential ingredient of Darwin's theory because the mechanism he proposed for evolution, natural selection, depends on the differential survival and reproduction of variants.

Darwin changed how we view variation. Before Darwin, variation was irrelevant, something to be ignored. After Darwin, it was recognized as the key to the evolutionary process. In this module, we will focus on variation—how to describe it, where it comes from, and how to measure it. When we have a way to measure genetic variation, we can follow it over time. If it changes, then we know that evolution is

occurring.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Focus on types and sources of genetic variation among individuals in a population.

Photo: Ralph Lee Hopkins/Getty Images

42.1 Variation is a notable feature of the natural world

Darwin started off with the observation that individuals of a species differ from one another, whether looking at pigeons, Galápagos finches, or even humans. In other words, variation is abundant in nature. Observable differences among individuals of a species are the result of differences in their genetic

material (DNA) as well as differences in the environment. We will explore these differences in this section.

Phenotypic Variation

Variation is a major feature of the natural world. We humans are particularly good at noticing variation among individuals of our own species. We differ in height, weight, facial features, skin color, eye color, hair color, hair texture, and many other ways.

As we saw in Unit 5, the observable traits of an organism are called the phenotype. The trait may be visible, as in characteristics such as weight or height, or it may be observed in the

development, physiology, or behavior of a cell or an organism. For example, color blindness and lactose intolerance are phenotypes, even though you can't "see" these traits by simple observation. They are considered phenotypes because they are both traits of organisms.

A phenotype results in part from an organism's genotype, its genetic makeup. For example, some individuals have a genotype with a mutation that affects expression of an enzyme that normally breaks down the sugar lactose. This genotype can lead to the phenotype of lactose intolerance. In addition, the environment commonly plays an

important role in phenotype. For example, weight is affected by diet, and skin color is affected by exposure to sunlight. As a result, it is most accurate to say that a phenotype reflects an interaction between the genotype and the environment.

Genotypic Variation

As we just discussed, the genetic makeup of a cell or organism constitutes its genotype. A population that has variation in many different genes consists of organisms with many different genotypes. Genotypic or genetic variation refers to differences in the DNA sequence among individuals of a species.

Genetic variation accounts in part for the physical differences we see among individuals, such as differences in hair color, eye color, and height. And, on a much larger scale, genetic differences among species has led to the diversity of organisms on this planet, from bacteria to blue whales.

The relationship between phenotype and genotype is typically not straightforward. Humans are phenotypically very variable—that is, many visible traits differ among humans. However, in spite of having a high degree of phenotypic variation, humans actually rank low in terms of overall genetic variation compared to

other species. Any two randomly selected humans differ from each other, on average, by one DNA base per thousand bases, which means that they are 99.9% genetically identical. By way of comparison, Adélie penguins (*Pygoscelis adeliae*), shown in **FIGURE 42.1**, are two to three times more genetically variable than humans (2–3 bases per thousand), even though they are one of the most phenotypically uniform species on the planet. And fruit flies (*Drosophila melanogaster*) are 10 times more genetically variable than humans (10 bases per thousand).

FIGURE 42.1 Genetic diversity in Adélie penguins

Adélie penguins look very similar to one another but are more genetically diverse than humans.

Genetic variation arises from mutations. Any heritable change in the nucleotide sequence of DNA is a mutation. By heritable, we mean that the mutation persists through DNA replication and is transmitted from parent cell to daughter cell through cell division. A change might be a substitution of one base for another, a small deletion or insertion of a few nucleotides, or a larger alteration affecting a segment of a chromosome, as described in Units 5 and 6. Most mistakes in DNA replication or chemical damage to

DNA are immediately repaired by specialized enzymes in the cell. Some, however, escape these repair mechanisms and are transmitted from parent cell to daughter cell.

A mutation occurs in an individual cell at a particular point in time. Through evolution, the proportion of individuals in a population carrying this mutation may increase or decrease. Therefore, if we look at any present-day population of organisms, such as the human population, we will find that it harbors many genetic differences, all the result of mutations that occurred sometime in the past.

We tend to think of mutations as something negative or harmful because in everyday language the term “mutant” suggests something abnormal. In reality, because mutations result in genetic variation among individuals, we are all “mutants” that differ from one another in our DNA. Although it is true that many mutations are harmful, other mutations have no or negligible effects on the organism, and a precious few are beneficial. Without mutations, evolution would not be possible. Mutations generate the occasional favorable variants that allow populations to evolve and organisms to become adapted to their environment over time, as we

discussed in Module 41.

AP® EXAM TIP

PREP FOR THE AP® EXAM

Remember that genetic variation is necessary for evolution by natural selection, but it is not the only factor. Genetic variation results in phenotypic variation which in turn can lead to differential survival and reproduction of individuals in a particular environment. As a result, the genetic makeup of the population changes from one generation to the next.

✓ Concept Check

1. **Describe** the difference between a phenotype and a genotype.

2. **Identify** two factors that result in phenotypic variation among individuals of a species.

3. **Describe** why a mutation may be harmful, be beneficial, or have no impact on the survival or reproduction of an individual.

42.2 Mutation and recombination are the two sources of genetic variation

Genetic variation refers to any difference in the DNA sequence among individuals of a species. If we focus our attention on genes, the regions of DNA that encode for proteins, we find that individuals

often have different gene sequences as well. The different forms or variants of a gene are alleles, and they correspond to different DNA sequences in the genes. In this section, we will discuss the two sources of genetic variation—mutation and recombination—and then characterize mutations.

Sources of Genetic Variation

Genetic variation that we observe in any present-day population of organisms has two sources. First, as we have seen, mutation generates new variation in DNA sequences. Second, recombination shuffles

existing variation to make new combinations. Recall from Module 26 that, in sexually reproducing organisms, a form of cell division called meiosis produces gametes, such as eggs and sperm. Meiosis generates daughter cells with half the number of chromosomes as the parent cell. Then, when fertilization occurs, the combination of genetic material from the egg and the sperm produces a new organism with the same number of chromosomes as the parents. During meiosis, chromosomes exchange DNA segments through recombination. This process shuffles mutations to create new combinations.

Because mutation and recombination lead to the formation of new alleles, both processes increase genetic variation. These two processes are shown in **FIGURE 42.2**. In generation 1, there is one allele. In generation 2, mutation of T to C creates a new allele (allele 2), so now there are two alleles in the population. In generation 3, mutation of T to G creates another new allele (allele 3), or three alleles in the population. In generation 4, recombination between allele 1 and allele 3 creates a new allele (allele 4). Over four generations, we see new alleles arising by both mutation and recombination.

FIGURE 42.2 Mutation and recombination

The formation of new alleles occurs by mutation in generations 1–3 and recombination in generation 4.

Although mutation and recombination can both create new genetic sequences and therefore increase genetic variation, all genetic variation ultimately comes from mutations. Recombination only increases genetic variation if the genetic sequences are different because of mutations that occurred in the past, as Figure 42.2 demonstrates. As a result, we say that mutations are the ultimate source of genetic variation, even though both processes contribute to genetic variation in

present-day populations.

Mutation Frequency

Mutations arise from mistakes in DNA replication or from unrepaired damage to DNA. Sources of the damage may include reactive molecules produced in the normal course of metabolism; chemicals in the environment; or radiation of various types, including X-rays and ultraviolet light. Most genomes also contain DNA sequences that can "jump" from one position to another in the genome. Insertion of these sequences into or near genes is also a source of mutation.

The rate at which mutations occur

differs among species. **FIGURE 42.3** compares the rates of newly arising mutations in a given nucleotide pair in a single round of replication in several viruses and several types of organisms. As seen in the graph, the mutation rates range across almost eight orders of magnitude, from about $10-3 10^{-3}$ mutations per nucleotide per replication in some viruses to about $10-11 10^{-11}$ mutations per nucleotide per replication in humans. This range reflects differences in the accuracy of DNA replication and the efficiency of DNA repair mechanisms.

FIGURE 42.3 Mutation rate

The rate of mutation for a specific

nucleotide in one round of DNA replication is very low, and it varies in different organisms.

Data from Drake, J. W., B. Charlesworth, and J. F. Crow. 1998. “Rates of Spontaneous Mutation.” *Genetics* 148:1667–1686.

Mutations are rare events when considered from the point of view of a particular base (nucleotide). In other words, if we consider a particular nucleotide and ask what’s the chance that it will undergo a mutation in a single round of replication, it’s very small. While the rate of mutation per nucleotide per replication in most organisms is low, the rate of mutation across an entire genome for *any*

nucleotide is higher, especially for organisms with large genomes. Therefore, although the probability of a change in a specific nucleotide is very low, the probability of a mutation anywhere in the genome is much higher.

The Random Nature of Mutations

Mutations occur randomly. What exactly does that mean? Consider the following experiment: an antibiotic is added to bacterial cells that are growing and dividing. Most of the cells are killed, but a few survivors continue to grow and divide. These survivors contain mutations that

confer resistance to the antibiotic. That is, the survivors with the mutations are not killed by the antibiotic. This simple observation raises two alternative hypotheses. First, the antibiotic-resistant mutations might have already been present before the antibiotic was added. Second, the antibiotic-resistant mutations might arise in response to the application of the antibiotic.

These alternative hypotheses have profound implications for all of biology because they suggest two very different ways in which mutations occur. The first suggests that mutations occur without regard to the

needs of an organism. According to this hypothesis, the presence of the antibiotic in the experiment with bacterial cells does not direct or induce antibiotic resistance in the cells. Instead, it kills off all but the small number of preexisting antibiotic-resistant mutants, which flourish. The second hypothesis suggests that some sort of feedback occurs between the needs of an organism and the process of mutation, as if the environment directs specific mutations that are beneficial to the organism.

We now know from many experiments in many species that the first hypothesis is correct—mutations

are random and do not occur out of need. One of these experiments was carried out by Joshua and Esther Lederberg in 1952. This experiment is summarized here and described in more detail in "Practicing Science 42.1: Do mutations occur randomly, or are they directed by the environment?"

Practicing Science 42.1

Do mutations occur randomly, or are they directed by the environment?

PREP FOR THE AP® EXAM

Background Researchers have long observed that beneficial mutations tend

to persist in environments where they are beneficial to an organism. For example, in the presence of antibiotics, bacterial populations evolve antibiotic resistance; in the presence of insecticides, insect populations evolve insecticide resistance.

Two Hypotheses These kinds of observations lead to two hypotheses about how a mutation, such as one that confers antibiotic resistance in bacteria, might arise. The first suggests that mutations occur randomly in bacterial populations and over time become more common in the population in the presence of an antibiotic that kills those bacteria that do not have the mutation. In other words, they occur randomly and independent of the needs of an organism. The second hypothesis

suggests that the environment, in this case the application of antibiotic, induces mutations that confer antibiotic resistance.

Method To distinguish between these two hypotheses, Joshua and Esther Lederberg developed a technique called replica plating. In this technique, bacteria are grown on plates of a solid gel-like medium containing agar and nutrients, where they form colonies of cells. The cells in any one colony result from the division of a single original cell, so all individual bacteria in a single colony are genetically identical except for rare mutations that occur in the course of growth and division. Then a disk of sterilized velvet is pressed onto the plate, shown in the figure to the right. The velvet disk picks up cells from

each colony and preserves their geometrical positions on the plate. The velvet disk is pressed onto the surface of a fresh plate, creating a replica of the original plate, hence the name replica plating. The velvet transfers to the new plate some of the cells that originate from the colony on the first agar plate in their original positions. This is key because it allows the researcher to expose the colonies on the replica plate to some sort of treatment, in this case, antibiotic, while also being able to go back and examine the exact same colonies on the original plate that were never exposed to antibiotic. In essence, the two plates create a “before” and “after” scenario of the same bacterial colonies.

Experiment and Results First, the Lederbergs grew bacterial colonies on a master plate containing medium without antibiotic. Then, by replica plating, they transferred some cells from each colony to two plates, shown in the following figure. One plate contained medium without antibiotic. This was the nonselective plate and served as the control; all cells were able to grow and form colonies on it. The second plate contained medium with antibiotic. This was the selective plate and served as the experimental treatment: only antibiotic-resistant cells multiplied and formed colonies on this plate because it contained antibiotic.

Because replica plating preserves the

arrangement of the colonies, the location of an antibiotic-resistant colony that grew on the selective medium revealed the location of its parental colony on the control plate. This allowed the researchers to go back to the master plate and find the colony that grew on the selective plate before it was exposed to the antibiotic. Therefore, in the final step of the experiment, shown here the Lederbergs went back to the parental colony, which had not been exposed to the antibiotic, and grew a culture of bacteria from this colony. This is a pure culture of antibiotic-resistant bacteria that were present on the original plate before the bacteria ever encountered antibiotics.

Conclusion The Lederbergs' experiment showed that antibiotic-resistant mutants arise before exposure to antibiotics, not as a result of it. Antibiotic-resistant bacteria were isolated in these experiments even though the parental cells on nonselective medium never came into contact with the antibiotic.

Follow-up Work These results have been extended to other types of mutation and other organisms, demonstrating that mutations are random and are not directed or induced by the environment.

AP® PRACTICE QUESTION

a. **Identify** the following:

1. The question being investigated by the experimenters
2. The hypotheses they tested
3. The experimental group
4. The control group
5. The independent variable
6. The dependent variable

b. **Explain** the results of the experiment by **identifying** the researchers' claim and **justifying** the claim with the evidence and the reasoning researchers used (CER).

In this experiment, bacterial cells were grown and formed colonies on agar plates in the absence of antibiotic. Then, using a technique

called replica plating, the Lederbergs transferred these colonies to new plates containing antibiotic. Only bacteria that were resistant to the antibiotic grew on the new plates. Because replica plating preserved the physical arrangement of the colonies, the Lederbergs were able to go back to the original plate and identify the colony that produced the antibiotic-resistant colony on the replica plate. From that original colony, they were then able to isolate a pure culture of antibiotic-resistant bacteria.

In the experiments, isolating antibiotic-resistant bacteria from the original plate showed that the mutation for antibiotic resistance

existed before the bacteria were ever exposed to antibiotic. This result supported the hypothesis that mutations occur randomly without regard to the needs of the organisms. The environment does not cause specific mutations, but instead selects for them. The principle that the Lederbergs demonstrated is true of all organisms so far examined.

Types of Mutations

Some features of mutations are particularly important for evolution. For example, we can consider whether mutations are passed on to offspring. Somatic mutations occur in the body's tissues in nonreproductive

cells. A somatic mutation affects only the cells descended from the cell in which the mutation originally arose, so it affects only that one individual and is not passed off to offspring. There are also germ-line mutations, which occur in the reproductive cells, such as eggs and sperm. Because germ-line mutations are passed to the next generation, they are of particular interest from an evolutionary standpoint.

We can also consider the effects that mutations have on an organism. Recall from Unit 6 that DNA is transcribed to mRNA, which is translated to proteins. Therefore, a change or mutation in DNA can be

transferred to mRNA and then to a protein. Proteins, in turn, do much of the work of the cell and make up the structure of cells and organisms. Therefore, mutations often exert their effects on an organism by changing the structure and hence the function of proteins. In other words, a change in a protein can, in some cases, result in a change in a trait in an organism.

A mutation can have many effects on an organism, but here we will focus on the influence a mutation has on the ability of an organism to survive and reproduce in a particular environment. Viewed in this way, mutations can be neutral, meaning that they have little or no effect on the

survival and reproduction of an organism. Every human is born with about 60 new mutations, but, because most of the genome consists of noncoding DNA, most of these are neutral. In contrast, a large proportion of mutations that occur in genes or protein-coding regions have a harmful effect on an organism and are known as deleterious mutations. These decrease a carrier's chances of survival and reproduction. Rarely, a mutation occurs that has a beneficial effect. A mutation is known as an advantageous mutation if it improves a carrier's chances of survival and reproduction. As we have seen, through natural selection, advantageous mutations can increase

in frequency in a population until eventually they are carried by every member of a species. These mutations result in a species that is adapted to its environment—better able to survive and reproduce in that environment.

Finally, we can consider the types of mutations that contribute to present-day genetic variation among individuals in a population. Different types of mutations are common in present-day populations of many species, including humans. These mutations occurred in the past, but then were retained and spread so that many individuals in a population share them.

FIGURE 42.4 reviews three major types of genetic variation, which we introduced in Unit 6. A mutation in which one base pair is replaced by a different base pair is called a point mutation. A point mutation in which a G–C base pair is replaced by an A–T base pair is shown in Figure 42.4a. Other relatively common types of mutations are duplications, in which a segment of DNA is repeated, and deletions, in which a segment of DNA is removed, which is shown in Figure 42.4b. If these mutations include one or more genes, the resulting change in gene copy number changes the amount of the protein products of these genes in the cell. Another type of mutation is the insertion of

movable DNA sequences into or near a gene. Such a “jumping” DNA sequence is called a transposable element and is shown in Figure 42.4c. The genomes of virtually all organisms contain several types of transposable elements, and each is present in multiple copies per genome, so they are quite common.

FIGURE 42.4 Common mutations in populations

Mutations are the ultimate source of genetic variation among individuals in a population. Common types of mutations we see in present-day populations include point mutations (a), duplications and deletions (b), and insertions of a transposable element (c).

✓ Concept Check

4. **Identify** the two sources of all present-day genetic variation among organisms.

5. **Identify** the ultimate source of all present-day genetic variation.

6. **Describe** what it means when scientists say that mutations are random.

7. **Identify** and **describe** three types of mutations.

42.3 Genetic variation is measured by allele frequencies

Most species harbor abundant genetic variation, such as the types of mutations shown in Figure 42.4. What factors determine the amount of variation in a species? Why are humans genetically less variable than

fruit flies and Adélie penguins? What factors affect the distribution of particular variations? The field of population genetics addresses these and other questions about patterns of variation. In this section, we will look at how scientists measure genetic variation and follow genetic variation in populations over time.

Populations

Every individual of a given species is different. For example, they have different combinations of alleles. All of the alleles present in all of the individuals in a species is called the gene pool for that species. The human gene pool includes alleles that

cause differences in skin color, hair type, eye color, and so on. Each one of us has a different set of those alleles—alleles that cause brown hair and brown eyes, for example, or alleles that cause black hair and blue eyes—drawn from that gene pool.

Individuals of a species share alleles through mating. Species represent individuals that are able to mate with each other and have fertile offspring. Therefore, a species consists of all the individuals that are capable, through reproduction, of sharing alleles with one another. A population is a subset of the individuals of a particular species that lives in one area. In other words, a population is an

interbreeding group of organisms of the same species living in the same geographical area.

Measuring Genetic Variation

To understand patterns of genetic variation in populations, we require information about allele frequencies. Allele frequencies provide a measure of genetic variation in a population. The allele frequency of an allele x is the number of allele x's present in the population divided by the total number of alleles of that gene. In other words, allele frequency is the proportion, among all the alleles of a gene in a population, that consists of

a particular allele.

Consider, for example, pea color in Mendel's pea plants, which we discussed in Unit 5. Pea color (yellow or green) is determined by variation at a single gene. Two alleles of this gene include the dominant *A* (yellow) allele and the recessive *a* (green) allele. *AA* homozygotes and *Aa* heterozygotes produce yellow peas, whereas *aa* homozygotes produce green peas. Imagine a population in which every pea plant produces green peas, meaning that only one allele, *a,* is present. In this population, the allele frequency of *a* is 100%, and the allele frequency of *A* is 0%. When a population exhibits only one allele at

a particular gene, we say that the population is fixed for that allele. In other words, the frequency of the allele is 1, and no other alleles for that gene exist in the population.

The genotype frequency of a population is the proportion of each genotype at a particular gene or set of genes. Consider another population of 100 pea plants with genotype frequencies of 50% *aa,* 25% *Aa,* and 25% *AA*. The genotype numbers for this population are 50 green pea homozygotes (*aa*), 25 yellow pea heterozygotes (*Aa*), and 25 yellow pea homozygotes (*AA*).

What is the allele frequency of *a* in

this population? First, we find the total number of *a* alleles in the population and divide by the total number of alleles in the population. Each of the 50 *aa* homozygotes has two *a* alleles and each of the 25 heterozygotes has one *a* allele. There are no *a* alleles in *AA* homozygotes. The total number of *a* alleles is therefore $(2 \times 50) + 25 = 125$ $(2 \times 50) + 25 = 125$. Because each pea plant is diploid, meaning that it has two alleles, the total number of alleles in the population of 100 pea plants is 200. To determine the allele frequency of *a,* we divide the number of *a* alleles, 125, by the total number of alleles in the population, 200:

$$125\ 200 = 0.625 = 62.5\ \%$$

$$\frac{125}{200} = 0.625 = 62.5\%$$

Because we are dealing with only two alleles in this example, we can calculate the allele frequency of *A* by subtracting the allele frequency of *a* from 100%:

$$100\ \% - 62.5\ \% = 37.5\ \%$$

$$100\% - 62.5\% = 37.5\%$$

The allele frequencies of *A* and *a* provide a measure of genetic variation at one gene in a given population. It would be a simple matter to measure genetic variation in a population if we could always use observable traits, as we did with the

pea plant example. By simply counting the individuals that displayed variant forms of a trait, we were able to determine a measure of the variation of that trait's gene. However, this approach works only rarely for two important reasons. The first reason is that many traits are encoded by a large number of genes. A good example is human height, which is influenced by variation in thousands of genes. In this and other similar cases, it is difficult, if not impossible, to make direct inferences from a phenotype to the underlying genotype. Even traits that seem to have a simple set of phenotypes often prove to have a complicated genetic basis. For instance, human skin color

is determined by at least six different genes. The second reason that we often can't use phenotype as a measure of genotype is that the phenotype is a product of both the genotype and the environment, as we discussed earlier.

Until the 1960s, only one workable solution was available: limit population genetics to the study of phenotypes that are encoded by a single gene, like color in pea plants. As these phenotypes are relatively rare, the number of genes that population geneticists could study was extremely small. Another example is certain markings in invertebrates. For example, the

coloring of the two-spot ladybug *Adalia bipunctata* shown in **FIGURE 42.5** is controlled by a single gene.

FIGURE 42.5 A single-gene trait

A genetic difference in color in the two-spot ladybug, *Adalia bipunctata,* results from variation in a single gene.

Genetic variation became much easier to measure in the 1960s with the application of gel electrophoresis, described in Unit 6. Gel electrophoresis separates segments of DNA according to their size. Before DNA technologies were developed, the same basic process was applied to proteins to separate them according to their electrical charge and their size. In gel electrophoresis, the

proteins being studied migrate through a gel when an electrical charge is applied. The rate at which the proteins move from one end of the gel to the other is determined by their charge and their size.

Early studies of protein electrophoresis focused on enzymes that catalyze reactions that produce a dye when the substrate for the enzyme is added. If researchers add the substrate, they can see the locations of the proteins in the gel. The bands in the gel provide a visual picture of genetic variation in the population, revealing which alleles are present and what their frequencies are.

"Practicing Science 42.2: How did gel electrophoresis allow us to detect genetic variation?" shows this sort of experiment. In this experiment, proteins from fruit flies are run on a gel. Each well of the gel is loaded with proteins from one individual. When an electrical current is applied, the proteins are separated by size and charge. The gel is then stained in such a way that a particular enzyme, called Adh, is visualized. The resulting bands give a picture of the genetic variation of the *Adh* gene in a population of eight fruit flies.

Practicing Science 42.2

How did gel electrophoresis

allow us to detect genetic variation?

PREP FOR THE AP® EXAM

Background The introduction of protein gel electrophoresis in 1966 gave researchers the opportunity to identify differences in amino acid sequence in proteins both among individuals and, in the case of heterozygotes, within individuals. In gel electrophoresis, proteins with different amino acid sequences move at different rates through a gel in an electric field. Often, a single amino acid difference is enough to affect the mobility of a protein in a gel.

Method Researchers load material derived from crude tissue—in this case,

the ground-up whole body of a fruit fly known as *Drosophila melanogaster*—on a gel. Each well of the gel (shown at the top of the gel) contains material from one fruit fly. Then the researchers turn on an electric current, placing the negative charge at the sample end and the positive charge at the other end of the gel. Proteins migrate toward the positive charge. The rate at which any given protein migrates depends on its size and its charge, both of which may be affected by its amino acid sequence.

To visualize the protein at the end of the gel run, researchers use a biochemical indicator that produces a stain when the protein of interest is active. In the experiment shown in the figure to the right, researchers used a biochemical indicator that detects the activity of a

protein called alcohol dehydrogenase (Adh). A series of bands on the gel shows where the Adh proteins in each lane migrated.

Results The *Adh* gene has two common alleles, which are distinguished by a single amino acid difference that changes the charge of the protein. One allele, *Fast* (*F*), runs more quickly than the other, *Slow* (*S*). In the following figure the gel shows that four individuals are *SS* homozygotes, two are *FF* homozygotes, and two are *FS* heterozygotes. Note that the *FS* heterozygotes do not stain as strongly on the gel because each band has half the intensity of the single band in the homozygotes.

We can measure the allele frequencies by counting the alleles. Each homozygote has two of the same allele, and each heterozygote has one of each.

Total number of alleles in the population of 8 individuals $= 8 \times 2 = 16$ $= 8 \times 2 = 16$

Number of *S* alleles in the population $= 2 \times (\text{number of SS homozygotes})$

$= 2 \times (\text{number of } SS \text{ homozygotes}) + \text{number of } FS \text{ heterozygotes}) = (2 \times 4) + 2 = 8 + 2 = 10$

$\text{Frequency of } \text{S} = 10\ 16 = 5\ 8$

$\text{Frequency of } S = \frac{10}{16} = \frac{5}{8}$

Number of *F* alleles in the population $= 2 \times (\text{number of FF homozygotes})$

$= 2 \times (\text{number of } FF \text{ homozygotes}) + \text{number of } FS \text{ heterozygotes}) = (2 \times 2) + 2 = 4 + 2 = 6$

$\text{Frequency of } \text{F} = 6\ 16 = 3\ 8$

$$\text{Frequency of } F = \frac{6}{16} = \frac{3}{8}$$

Note that the allele frequency of *S* and the allele frequency of *F* add to 1.

Conclusion The experiment provides a profile of genetic variation at this gene for these eight individual fruit flies. Population genetics involves comparing data such as these with data collected from other populations to determine the mechanisms shaping patterns of genetic variation.

Follow-up Work This technique is seldom used now because it is easy to recover much more detailed genetic information about genetic variation from DNA sequencing.

SOURCE

Lewontin, R. C., and J. L. Hubby. 1966. “A

Molecular Approach to the Study of Genic Heterozygosity in Natural Populations: II. Amount of Variation and Degree of Heterozygosity in Natural Populations of *Drosophila pseudoobscura*." *Genetics* 54:595–609.

AP® PRACTICE QUESTION

a. **Identify** the following:

   1. The question the experimenters are trying to answer
   2. The hypothesis they tested
   3. The independent variable
   4. The dependent variable

b. **Explain** the results of the experiment by **identifying** the researchers' claim and **justifying** the claim with the evidence and the reasoning researchers used (CER).

Protein gel electrophoresis was a leap

forward in our ability to detect genetic variation, but this technique had significant limitations. Researchers could study only enzymes because they needed to be able to stain for enzyme activity. The technique also could detect only mutations that resulted in amino acid substitutions that changed a protein's mobility in the gel. Some mutations do not change the charge or size of the protein, so are not detected by this technique.

Only with DNA sequencing did researchers finally have an unambiguous means of detecting all genetic variation in a stretch of DNA, whether in genes or not. The

variations studied by modern population geneticists are differences in DNA sequence, such as an A rather than a G at a specified nucleotide position in a particular gene.

Calculating allele frequencies with DNA sequencing involves collecting a population sample and counting the number of occurrences of a given mutation. For example, researchers can look even more closely at the example of the *Drosophila Adh* gene identified in Practicing Science 42.2 to focus not on the amino acid difference between the *Fast* and *Slow* phenotypes, but on the A or G nucleotide difference underlying the two phenotypes.

If researchers sequence the *Adh* gene from 50 individual flies, they then have 100 gene sequences from these individuals because fruit flies are diploid and carry two copies of the *Adh* gene. If they find that 70 sequences have an A and 30 have a G at the position in question, the allele frequency of A is $70100 = 0.7 \frac{70}{100} = 0.7$ and the allele frequency of G is 0.3. In general, in a sample of *n* diploid individuals, the allele frequency is the number of occurrences of that allele divided by twice the number of individuals in the sample.

The ability to determine allele frequencies gives scientists the ability to measure genetic variation. With

this information in hand, they can then follow genetic variation over time. If they find that it changes, they can infer that evolution is occurring.

AP® EXAM TIP

PREP FOR THE AP® EXAM

Make sure you know how to calculate allele frequencies from genotype frequencies and genotype numbers; past exams have required this skill.

✓ Concept Check

8. **Describe** how population geneticists measure genetic variation.

9. **Describe** allele frequency.

10. **Calculate** the allele frequency if there are 25 copies of allele *A* in a

total of 100 copies of alleles of that gene.

Module 42 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Describe two processes

that can contribute to genetic variation in a population.

LG 42.1 Variation is a notable feature of the natural world.

- Phenotypic variation is differences in the observable traits of a cell or organism. Page 587
- Phenotypic variation results from genetic variation and environmental variation. Page 587
- Genotypic or genetic variation is differences at the level of DNA sequences. Page 588

LG 42.2 Mutation and recombination are the two sources of genetic variation.

- Different forms (sequences) of genes are called alleles. Page 589
- Mutation and recombination are the two sources of genetic variation, but all genetic variation ultimately comes from mutation. Page 589
- Mutations are rare for a given base (nucleotide), but common across an entire genome. Page 590
- Mutations are random with respect to the needs of an organism. Page 590
- Mutations can be either somatic (in body tissues) or germ line (in gametes); germ-line mutations are the only ones that can be passed on to the next generation.

Page 592

- Mutations can be neutral, deleterious, or advantageous. Page 592
- A point mutation is a change of one base for another. Page 593
- Small insertions (or deletions) in DNA add (or remove) one base or a few bases. Page 593
- A duplication is a region of the chromosome that is present two times, and a deletion is the loss of part of a chromosome. Page 593
- Transposable elements are DNA sequences that can jump from one place to another. Page 593

LG 42.3 Genetic variation is measured by allele frequencies.

- Patterns of genetic variation are described by allele frequencies. Page 593
- An allele frequency is the number of occurrences of a particular allele divided by the total number of all alleles of that gene in a population. Page 594
- In the past, population geneticists relied on observable traits determined by single genes and protein gel electrophoresis to measure genetic variation. Page 594
- DNA sequencing is now the standard technique for measuring genetic variation in a population of individuals. Page 597

Review Questions

1. All the alleles present in all individuals in a species are referred to as

A. allele frequency.
B. genotype frequency.
C. genotype.
D. gene pool.

2. Genetic variation has two sources: mutation and

A. recombination.
B. natural selection.
C. nonrandom mating.
D. cell division.

3. What kind of mutation has no effect on an organism's ability to survive or reproduce?

A. A deleterious mutation
B. A neutral mutation
C. An advantageous mutation
D. An adapted mutation

4. A population refers to a group of organisms that are in the same geographic area and that

A. are genetically related.
B. have the similar phenotype.
C. cannot interbreed.
D. are the same species.

5. Genetic variation in a population refers to

A. multiple individuals breeding together.
B. multiple alleles within a gene pool.

C. multiple phenotypes with the same genotype.
D. multiple genes within a genome.

6. Using visual observation of phenotypes to identify allele frequencies rarely works because

A. most alleles are dominant and will not produce a visible phenotype.
B. phenotype is not due to the alleles.
C. multiple genes may control the phenotype.
D. visual phenotypes are rare.

7. If a gene has two alleles, and allele *A* has a frequency of 83%, allele *a* has

a frequency of:

A. 17%.

B. 117%.

C. 41.5%.

D. 7%.

Module 42 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–3.

1. The rate of mutation in human germ-line cells has been

estimated to be approximately $1.3 \times 10 - 8$ 1.3×10^{-8} per base pair per generation. The human genome size, consisting of a diploid complement of chromosomes, is approximately 6.4×109 6.4×10^{9} base pairs. Which is the most likely number of new mutations present in a human baby but not present in either parent?

A. 166.4

B. 83.2

C. 41.6

D. 24.6

Use the following information to answer questions 2 and 3.

Threespine sticklebacks are small fish that sometimes have bony plates along their sides, which protect them from the bite of predators. Genetic variation in the *Eda* gene of threespine sticklebacks determines the amount of the bony plating. Fish that are homozygous for the Eda218 Eda^{218} allele are completely plated, fish that are homozygous for the Eda158Eda^{158} allele are unplated, and fish that are heterozygous for the two alleles are partially plated. The figure shows data that researchers collected in a population of sticklebacks over several different years in a single place.

Data from Kitano, J., et al. 2008. “Reverse Evolution of Armor Plates in the Threespine

Stickleback." *Cell* 18(10):769–774.

1. What percentage of threespine sticklebacks sampled in 1976 were completely plated?

   A. 25%
   B. 40%
   C. 50%
   D. 60%

2. What is the difference in the frequency of the of the Eda158 Eda^{158} allele between 1957 and 2005?

   A. 49%
   B. 55%
   C. 62%

D. 75%

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Atlantic cod is a species of fish. Variation in the hemoglobin protein of cod can be observed with gel electrophoresis. Protein encoded by the Hbl1 Hbl^1 allele of the *hemoglobin* gene moves more quickly through a gel than the protein encoded by the Hbl2 Hbl^2 allele of the gene. A scientist collected 15 cod from the

ocean near the east coast of Norway and 15 cod from the ocean near the west coast of Norway, purified the hemoglobin protein, and separated the hemoglobin proteins on a gel. Each well of the gel was loaded with the hemoglobin proteins of a single fish. The figure shows the data that were obtained.

a. **Identify** the sampling site with a higher frequency of heterozygotes for the *hemoglobin* gene.
b. **Calculate** the allele frequency of the Hbl1 Hbl^1 allele in the sample from the west coast of Norway.

Module 43

Hardy–Weinberg Equilibrium

LEARNING GOALS

- **LG 43.1 Evolution is a change in the genetic makeup of a population over time.**
- **LG 43.2 There are five mechanisms of evolution.**
- **LG 43.3 The Hardy–Weinberg equilibrium occurs when the genetic makeup of a population does not change over time.**

In the last module, we focused on variation. Individuals of a species are different from one another. These observable differences result from both genetic and environmental variation. Genetic variation in turn results from mutation and recombination. We can measure genetic variation in a population by determining allele frequencies—the number of a specific allele out of the total number of alleles of a gene in the entire population.

When we have allele frequencies, we can then follow them over time. In other words, we can sample a population at one time and come back after several generations and

sample it again. What will we find? We might find that allele frequencies have changed. This is evolution—the change in the genetic makeup of a population over time. Allele frequencies can change for a variety of reasons. These reasons are associated with different mechanisms of evolution. We have already discussed natural selection in Module 40. Natural selection is one of five mechanisms of evolution. In this module, we will take a closer look at the relationship between genetic change and evolution. We will consider the five mechanisms by which the genetic makeup of a population changes over time. Finally, we will look at conditions in which

allele frequencies do not change.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Focus on the mechanisms or processes that can lead to changes in the genetic makeup of populations over time.

Photo: Micro Discovery/Getty Images

43.1 Evolution is a change in the genetic makeup of a population over time

Measuring and following changes in genetic variation over time is key to understanding the genetic basis of evolution. Genetic variation can be measured in two ways. One way is by determining the allele frequency of a particular gene. Recall that the allele

frequency is the number of occurrences of a particular allele divided by the total number of occurrences of all the alleles of a gene in the population. We can also measure genetic variation by determining genotype frequency, which is the number of occurrences of a particular genotype divided by the total number of occurrences of all the genotypes for a gene in a population.

Let's consider a simple example. Red blood cells in your body, shown in **FIGURE 43.1**, have molecules on their surfaces that determine your blood type. One group of molecules goes by the name ABO blood group. The ABO

blood group is the result of variation in a single gene, called the *ABO* gene. This gene has three alleles—*A, B,* and *O*. The allele frequency of allele *A* is the number of *A* alleles in the population divided by the total number of alleles of the *ABO* gene. For example, if there are 25 copies of *A* in a population, and the total number of alleles *A, B,* and *O* is 100, then the frequency of allele *A* is 25 divided by 100, or 25100=14=0.25 $\frac{25}{100}=\frac{1}{4}=0.25$. This provides one way to measure genetic variation in the ABO blood group.

FIGURE 43.1 Red blood cells

Red blood cells have molecules on their surface that determine blood type.

Although there are three alleles of the *ABO* gene in the population, an individual can only have at most two different alleles because humans are diploid, meaning that they have two copies of each chromosome with one allele on each chromosome. So, there are six possible genotypes—*AA, AO, BB, BO, AB,* and *OO*. To calculate the genotype frequency, we divide the number of people with one of the genotypes by the total number of people. So, if 10 people are *AA* in a population of 100 people, then the genotype frequency of *AA* is 10 divided by 100, or 10100 = 1100 = 0.1 $\frac{10}{100} = \frac{1}{100} = 0.1$.

The phenotype is blood type. Blood

type A consists of people who have the genotypes *AA* or *AO;* blood type B consists of people who have the genotypes *BB* or *BO;* blood type AB is genotype *AB;* and blood type O consists of people who have the genotype *OO*. So, for the *ABO* gene, there are three alleles, six genotypes, and four phenotypes. **TABLE 43.1** summarizes the ABO blood group.

Phenotype	Genotype
A	*AA* or *BO*
B	*BB* or *BO*
AB	*AB*
O	*OO*

TABLE 43.1 The ABO Blood Group

When we have a measure of genetic variation, we can follow it over time. At the genetic level, evolution is a

change in the frequency of an allele or a genotype from one generation to the next. For example, if there are 200 copies of an allele that causes blue eye color in a population in generation 1, and there are 300 copies of that allele in a population of the same size in generation 2, evolution has occurred.

Evolution is a change in the genetic makeup of a population over time. In principle, evolution may occur when allele frequencies change, genotype frequencies change, or both allele and genotype frequencies change. For instance, in the example of blood types, we might see a change in the *A, B,* and *O* allele frequencies over time,

which is evolution. Because genotypes are made up of two alleles (*AA, AO, BB, BO, AB, OO*), a change in allele frequency will also cause a change in genotype frequencies. Furthermore, even if the *A, B,* and *O* allele frequencies stay the same from one generation to the next, the frequencies of the different genotypes may change. This would be evolution without allele frequency change.

Note that this definition of evolution makes it clear that populations rather than individuals evolve. In other words, if we consider a population of individuals at one time and compare it to a population at a later time, we may see a change in allele

frequencies, genotype frequencies, or both. Any of these changes in the genetic makeup of a population represents evolution. Individuals may also change over time, such as the changes that you experience as you grow up and develop, but this type of change is not considered evolution.

The definition of evolution does not specify a mechanism for this change. As we will see, several mechanisms can cause allele or genotype frequencies to change. Regardless of which mechanisms are involved, any change in allele frequencies, genotype frequencies, or both constitutes evolution.

✓ Concept Check

1. **Describe** the genetic basis for evolution.

2. A particular gene has two alleles denoted *C* and *c*. **Identify** all the possible genotypes.

3. Assume there are 30 *C* alleles and 20 *c* alleles at a particular gene in a population. **Calculate** the frequency of *C* in the population.

43.2 There are five mechanisms of evolution

We have seen that evolution is a change in allele frequency, genotype frequency, or both in a population over time. What causes these frequencies to change from one generation to the next? There are five

ways that they can change, and therefore five mechanisms of evolution. Natural selection is one of them, but not the only one. However, natural selection is the only mechanism that causes both evolution and adaptation. In this section, we will examine the five mechanisms of evolution, beginning with natural selection.

Natural Selection

In Modules 40 and 41, we discussed evolution by natural selection. In natural selection, some individuals survive and reproduce more than others. For example, in a population of birds, some may have lighter-

colored feathers than others, as shown in **FIGURE 43.2**. If the lighter birds survive and reproduce more than others in a particular environment, the population will consist of more lighter-colored individuals over time.

FIGURE 43.2 Natural selection

In this population of birds, there is variation in color, with some having lighter feathers and some having darker feathers. The lighter birds survive and reproduce more than the darker birds in a particular environment. As a result, the population of birds becomes lighter over time.

Natural selection causes allele and genotype frequencies to change over time. Let's consider a gene with two alleles, *A* and *a*. Now let's imagine that the alleles affect the ability of individuals to survive. For example, the allele *a* could be a recessive lethal mutation. In other words, all individuals of genotype *aa* die. In every generation, then, there is a selective elimination of *a* alleles, meaning that the frequency of *a* will gradually decline and the frequency of *A* will correspondingly increase over the generations.

As we discussed earlier, the individuals carrying these alleles have different levels of fitness, the ability

to survive and reproduce in a particular environment. In this case, *AA* and *Aa* individuals survive and reproduce well, but *aa* individuals don't. Because there is differential success of these alleles based on differences in the fitness of individuals, we call this mechanism of evolution natural selection.

Natural selection is evolution's major driving force, preferentially passing on to each successive generation those mutations that best fit organisms to their environments. As a result, they lead to impressive adaptations, like the camouflage of the katydid shown in **FIGURE 43.3**. This katydid is almost

indistinguishable from a dead leaf, providing protection against predators. However, natural selection is not the only evolutionary mechanism. Other mechanisms can cause allele and genotype frequencies to change as well. Unlike natural selection, however, they do not lead to a population being better adapted to their environment or to a population being more fit.

FIGURE 43.3 A camouflaged katydid

This katydid looks like a dead leaf, providing camouflage and protection against predators. Adaptations such as this one evolve by natural selection.

Genetic Drift

Allele and genotype frequencies can also change over time simply as a result of chance. **Genetic drift** is the random change in allele frequencies from generation to generation. By "random," we mean that frequencies go up or down simply by chance. Let's go back to our example of birds with light and dark feathers. Let's imagine that a sudden storm eliminates much of a bird population, leaving by chance birds with an intermediate feather color, as shown in **FIGURE 43.4**. The survivors will breed and the population will end up being an intermediate color. The survival of the intermediate-colored birds had nothing to do with their color; they survived simply by chance.

FIGURE 43.4 Genetic drift

Genetic drift occurs when allele and genotype frequencies change by chance. In this example, a sudden storm eliminates much of the population, leaving by chance intermediate-colored birds. These birds go on to breed, resulting in a population of intermediate-colored birds.

In the last section, we considered what happens to beneficial and harmful mutations under the influence of natural selection. What about neutral mutations that are neither beneficial nor harmful? Natural selection, by definition, does

not affect what happens to neutral mutations. Consider a neutral mutation, *m,* which has no effect on survival and reproduction (fitness). At first, it is present in just a single individual. What happens if that individual fails to reproduce for reasons unrelated to *m?* In this case, *m* is lost from the population, but not by natural selection because *m* is neutral and natural selection has selected neither for nor against *m*. Rather, the loss of *m* is due to chance, so it represents a case of genetic drift. Alternatively, the *m*-bearing individual might by chance leave many offspring, again for reasons unrelated to *m*. In this case, the frequency of *m* increases due to

genetic drift.

While natural selection only acts on beneficial and harmful alleles, but not neutral alleles, genetic drift acts on all alleles regardless of their effects on fitness because it is a random process. Like natural selection, genetic drift leads to allele frequency changes and, therefore, evolution. Unlike natural selection, however, genetic drift does not lead to adaptations because the alleles whose frequencies are changing do not affect an individual's ability to survive or reproduce.

Now let's consider two situations in which we commonly see genetic drift

in action. Consider a rare allele, *A*, with a frequency of 1 1000 $\frac{1}{1000}$. Imagine that habitat destruction reduces the population to just one pair of individuals, and one of those, by chance, is a heterozygote carrying *A*. The frequency of *A* in this new population is 1 4 = 0.25 $\frac{1}{4} = 0.25$ because each individual has two alleles, giving a total of four alleles. So, we see that there was a large change in allele frequency following the habitat destruction event, from 1 1000 to 1 4 $\frac{1}{1000} = \frac{1}{4}$.

When a large population is reduced to just a few individuals, we say the population experiences a **bottleneck**, as in the example of the birds shown

in Figure 43.4. Genetic drift often results from population bottlenecks. A population of Galápagos tortoises (*Chelonoidis*) probably went through such a bottleneck about 100,000 years ago when a volcanic eruption eliminated most of the tortoises' habitat. One of these tortoises is shown in **FIGURE 43.5.** As a result, allele frequencies likely changed, just as in the example above.

FIGURE 43.5 A Galápagos tortoise

A population of Galápagos tortoises underwent a population bottleneck after a volcanic eruption, resulting in genetic drift and reducing genetic variation.

Genetic drift also commonly occurs

by a *founder effect*. A **founder effect** occurs when a few individuals from a larger population establish a new population. Such events occur, for example, when a small number of individuals arrive on an island from a nearby continent and colonize it, as illustrated in **FIGURE 43.6**. We also see founder effects in the human population when small groups of people leave one area and set up a population elsewhere. Once again, allele frequencies are randomly changed compared to the parent population.

FIGURE 43.6 Founder effect

A founder effect occurs when a few, random individuals of a larger

population colonize a new area, such as the island shown here. The result is that the new population and parent population have different allele frequencies.

With both a bottleneck effect and a founder effect, the allele frequency of the new population is different from the original population due to genetic drift. In addition, there is typically a large loss of genetic variation that occurs in both processes. The new, smaller population typically contains just a subset of the alleles present in the original population. As a result, the original population and the new population may end up being quite

different from each other genetically.

Genetic drift occurs in all finite populations, but its impact depends on population size. Genetic drift acts strongly in small populations and weakly in large populations. The reason is that random effects have more of an impact on small populations than on large ones. If you flip a coin 1000 times, you expect approximately 50% heads and 50% tails. However, if you flip a coin four times, you wouldn't be surprised if you got three heads and one tail, which is 75% heads and 25% tails. In other words, in small samples, chance plays a bigger role than in large ones. The same is true of

genetic drift: it is likely to be much more significant in small populations than in large ones.

FIGURE 43.7 uses four computer simulations to show the effect of population size on allele frequencies subject to genetic drift. In Figure 43.7a, the population size is very small, with just 4 individuals. At the start of the simulation, the frequency of a particular allele is 0.5. The change in allele frequency that is seen in each generation is just the result of chance. After a few generations, the frequency increases to 1.0, meaning that the allele is fixed in the population and all members of the population have it. The frequency

of the allele changes very quickly because the population is so small.

FIGURE 43.7 The effect of population size on genetic drift

Four computer simulations are shown. In each case, the starting allele frequency is 0.5, but the size of the population varies from 4 (a and b) to 40 (c) to 400 (d). In all simulations, the allele is fixed $(\text{frequency} = 1)$ $(\text{frequency} = 1)$ or lost $(\text{frequency} = 0)$ $(\text{frequency} = 0)$, but the process is more rapid in the smaller populations compared to the larger ones.

In Figure 43.7b, the same simulation is run six times, indicated by the blue

lines. Note that the blue lines are all different, meaning that genetic drift follows different paths each time. This is because genetic drift is random. Note too that sometimes the allele is fixed (frequency $= 1$) $(\text{frequency} = 1)$ and sometimes it is lost (frequency $= 0$) $(\text{frequency} = 0)$. This is another feature of genetic drift—alleles can be fixed or lost randomly.

Figure 43.7c and Figure 43.7d show larger populations of 40 and 400 individuals, respectively. In each figure, the simulation is again run six times. We see the same patterns in these two graphs—populations take random paths, and alleles are fixed or

lost—but the process is slower in these larger populations than in the smaller population shown in Figure 43.7b. So, we see that genetic drift acts strongly in small populations and less strongly in large populations.

Migration

Natural selection and genetic drift are two mechanisms of evolution. A third mechanism is *migration*. **Migration** is the movement of individuals from one population to another, as shown in **FIGURE 43.8**. In this example, there is a population of light-colored birds and a separate, nearby population of dark-colored birds of the same species. If some dark-

colored birds migrate into the territory of the of the light-colored bird population, the genetic makeup of the population of light-colored birds will change.

FIGURE 43.8 Migration

Migration is the movement of individuals between populations. Consider two populations of birds all of one species—one population with light-colored birds, and another population with dark-colored birds. Some of the dark-colored birds move into the population of light-colored birds, which in turn changes the genetic makeup of the population of light-colored birds.

Migration causes **gene flow**, the movement of alleles from one population to another. To see how migration and gene flow can lead to changes in allele frequencies, let's consider two populations. The first population contains only *A* alleles and the second contains a mix of *A* and *a* alleles. If there is a sudden influx of individuals from the second population into the first, the frequency of *A* in the first population will decline in proportion to the number of immigrants as *a* alleles enter the population. In other words, we see a change of allele frequency in the first population due to the migration of individuals and genes into that population.

Migration typically makes populations more similar to each other, reducing the genetic differences between them. Consider two isolated island populations of rabbits, one brown and the other black. Now imagine that the isolation breaks down—a bridge is built between the islands—and migration occurs between the two populations. Over time, black alleles enter the brown population, and vice versa, and the allele frequencies of the two populations gradually become the same.

Migration is sometimes used in conservation efforts as a way to increase genetic variation in

endangered or threatened species, such as the Arctic fox (*Vulpus lagopus*) shown in **FIGURE 43.9**. In the late nineteenth century, hunting significantly reduced the population of Arctic foxes in Scandinavia. This is an example of a population bottleneck, which reduced both the size and genetic variation of the population of foxes. As part of an effort to restore the population, foxes from a captive breeding program were introduced into the area. This assisted migration increased the size and genetic variation of the population and helped the population to recover.

FIGURE 43.9 An Arctic fox

A population of Artic foxes was reduced to low levels in Scandinavia due to hunting. As one part of an effort to restore the population, foxes were moved from a captive breeding program into the threatened population, thereby restoring the health and genetic variation of the population. Migration between populations is a mechanism of evolution because it changes allele frequencies.

Mutation

Mutation is a fourth mechanism of evolutionary change. As we have seen, mutation is the source of new alleles and the raw material on which the other mechanisms of evolution

act. Without mutation, there would be no genetic variation and no evolution. In addition, mutation itself is a mechanism of evolution. Going back to our example of a population of birds, a mutation that causes yellow wing bands might occur in an individual, as shown in **FIGURE 43.10**. This new mutation in the population introduces genetic variation and changes the genetic makeup of the population.

FIGURE 43.10 Mutation

Mutation is both the source of genetic variation and a mechanism of evolution. In this example, a mutation occurs in one individual that results in yellow bands on the wings.

From a genetic perspective, if *A* alleles mutate into *a* alleles, then we will see changes in the allele frequencies over the generations. However, because mutation is so rare, it has a very small effect on changing allele frequencies on the timescales studied by population geneticists. Mutation has a significant effect on populations in the long term but does not typically have a large effect on an entire population in the short term.

Nonrandom Mating

A fifth way that a population can evolve is by mating nonrandomly. In

our population of birds that vary in color, if light birds tend to mate with light birds, and dark birds tend to mate with dark birds, they are mating nonrandomly with respect to feather color, as shown in **FIGURE 43.11**.

FIGURE 43.11 Nonrandom mating

Nonrandom mating occurs when individuals do not mate randomly. In this example, light-colored birds mate with each other, and dark-colored birds mate with each other.

In random mating, individuals select mates without regard for genotype. In **nonrandom mating**, by contrast, individuals preferentially choose

mates according to their genotypes. The result is that certain genotypes increase and others decrease in frequency. For example, in random mating, an *AA* homozygote, when offered a choice of mate from among *AA, Aa,* or *aa* individuals, chooses at random. In contrast, in nonrandom mating, *AA* homozygotes might preferentially mate with other *AA* homozygotes, and *aa* homozygotes might preferentially mate with other *aa* homozygotes.

Nonrandom mating rearranges alleles already in a population's gene pool. As a result, genotype frequencies change. Unlike migration or mutation, nonrandom mating does

not add new alleles to the population. As a result, allele frequencies do not change. In this way, nonrandom mating is unique among the mechanisms of evolution in that it affects genotype frequencies from generation to generation, but does not affect allele frequencies. As we saw, the other four mechanisms change allele frequencies (as well as genotype frequencies).

An example of nonrandom mating that we see in some populations is inbreeding. Inbreeding occurs when there is mating between close relatives. Consider a rare allele *b* that has a frequency of 0.001 in a population. In random mating, the

expected frequency of a *bb* homozygote
is $0.001 \times 0.001 = 0.000001$
$0.001 \times 0.001 = 0.000001$.

What happens to the frequency of *bb* homozygotes when there is inbreeding? Suppose a male with one *b* allele has two offspring—one male and one female. The probability that the male offspring inherited the allele from his father is 0.5, and the same is true for the female offspring. Now suppose these offspring mate with each other. The probability of a *bb* homozygote from this mating is the probability each sibling inherited a copy from their father (0.5×0.5)
(0.5×0.5) multiplied by the probability

that their offspring inherited *b* from both of them (0.5 × 0.5) (0.5×0.5), or a total probability of (0.5) 4 = 0.0625 $(0.5)^4 = 0.0625$.

Clearly, 0.0625 is a considerably higher frequency than 0.000001. So, we see that the frequency of homozygotes increases in nonrandom mating compared with random mating. As the frequency of homozygotes increases, the frequency of heterozygotes decreases because genotypes can only be heterozygous or homozygous. This is significant from an evolutionary point of view because rare recessive mutations that are present in the population have a higher probability

of being homozygous and therefore expressed when inbreeding occurs. As some rare recessive mutations are harmful (for example, they may cause disease when homozygous), they can in turn affect the fitness of the population.

✓ Concept Check

4. **Identify** the five mechanisms of evolution.

5. **Identify** the mechanism of evolution that leads to adaptations.

6. **Describe** the process by which adaptations evolve.

7. **Identify** and **describe** the mechanism of evolution that causes

genotype frequencies to change, but not allele frequencies.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

43.3 The Hardy–Weinberg equilibrium occurs when the genetic makeup of a population does not change over time

Allele and genotype frequencies

change over time only if specific mechanisms act on the population. These mechanisms are natural selection, genetic drift, migration, mutation, and nonrandom mating. If these mechanisms are not acting, then allele and genotype frequencies don't change. This principle, which was demonstrated independently in 1908 by both the English mathematician G. H. Hardy and the German physician Wilhelm Weinberg, has become known as the **Hardy–Weinberg equilibrium**. In this section, we will describe the conditions in which allele and genotype frequencies do not change. We will also see how the Hardy–Weinberg equilibrium provides a

useful null hypothesis for studies about evolution.

The Five Conditions of the Hardy–Weinberg Equilibrium

In essence, the Hardy–Weinberg equilibrium describes the situation in which evolution does not occur. When none of the five mechanisms of evolution are acting, evolution does not occur. The conditions or assumptions of the Hardy–Weinberg equilibrium are therefore the following:

1. There is no difference in survival

and reproductive success among individuals. In other words, selection is not operating.
2. The population is infinitely large so the role of chance or genetic drift is eliminated.
3. Populations are not added to or subtracted from by migration.
4. There is no mutation.
5. Individuals mate at random.

According to the Hardy–Weinberg equilibrium, the allele and genotype frequencies of a population don't change when these five conditions are met. If allele and genotype frequencies do not change, we can conclude that evolutionary mechanisms are not acting in the population we are studying. In many

ways, then, the Hardy–Weinberg equilibrium provides a useful baseline or starting point for evolutionary studies. We can begin by testing whether a population is at Hardy–Weinberg equilibrium. If it is at Hardy–Weinberg equilibrium, then the population is not evolving. If it is not at Hardy–Weinberg equilibrium, then we can conclude that one or more of the conditions are not met and evolutionary mechanisms are at work. This is just a starting point, as the next step would be to figure out which of the five evolutionary mechanisms is acting on the population under study.

Relationship

between Allele and Genotype Frequencies

As we have seen, when the five conditions of the Hardy–Weinberg equilibrium are met, the population is not evolving. Furthermore, under these conditions, we are able to calculate genotype frequencies from allele frequencies. Let's return to the example of Mendel's peas that we looked at in Unit 5. In this example, there are two alleles, *A* and *a,* that determine pea color. In a population of pea plants, we find 70 *A* alleles and 30 *a* alleles. What are the genotype frequencies? In other words, how many *AA* homozygotes, *Aa*

heterozygotes, and *aa* homozygotes are there in the population? If the population is not in Hardy–Weinberg equilibrium, it is not possible to figure out genotype frequencies from allele frequencies. However, if the population is in Hardy–Weinberg equilibrium, we can determine genotype frequencies from allele frequencies.

Recall that random mating is a condition that must be met if a population is in Hardy–Weinberg equilibrium. Random mating is the equivalent of putting all the population's gametes into a single pot and drawing out pairs of them at random to form zygotes. This is the

same principle we saw in action in the discussion of independent assortment in Module 27. If there are 70 *A* alleles and 30 *a* alleles and mating is random, what is the probability of picking an *AA* homozygote? That is, what is the probability of picking an *A* allele followed by another *A* allele? The probability of picking an *A* allele is the same as the *A* allele's frequency in the population. Therefore, the probability of picking the first *A* is 70 100 = 0.7 $\frac{70}{100} = 0.7$. What is the probability of picking the second *A*? Also 0.7. The probability of picking an *A* followed by another *A* is the product of the two probabilities: $0.7 \times 0.7 = 0.49$

$0.7 \times 0.7 = 0.49$. In other words, there is a 49% probability of picking an *AA* homozygote. That means that the frequency of an *AA* genotype is 0.49.

We can follow the same steps to determine the genotype frequency for the *aa* genotype. The probability of picking the first *a* is 30 100 = 0.3 $\frac{30}{100} = 0.3$. The probability of picking a second *a* allele is also 0.3. The probability of picking an *a* followed by another *a* is the product of the two probabilities: 0.3 × 0.3 = 0.09 $0.3 \times 0.3 = 0.09$. So, there is a 9% probability of picking an *aa* homozygote. That means the frequency of an *aa* genotype is 0.09

What about the genotype frequency of the heterozygote, *Aa?* If mating is random and a population is in Hardy–Weinberg equilibrium, what is the probability of an *Aa* heterozygote? We compute this value by determining the probability of drawing *A* followed by *a,* or *a* followed by *A*. In other words, there are two different ways in which we can generate the heterozygote. Its frequency is therefore $(0.7 \times 0.3) + (0.3 \times 0.7) = 0.4$ $(0.7 \times 0.3) + (0.3 \times 0.7) = 0.42$, so there is a 42% probability of picking an *Aa* heterozygote. Note that the frequencies of the three genotypes (*AA, Aa, aa*) sum to 1 because there are only three genotypes in the entire population.

We can generalize these calculations by substituting letters for the numbers. Let the allele frequency of one allele, *A,* equal *p,* and the frequency of the other allele, *a,* equal *q*. Because there are no other alleles at this gene, the allele frequencies must add to 1 (or 100%). Therefore, we can write the following equation:

$$p + q = 1$$

We can also determine genotype frequencies given a set of allele frequencies. If the frequency of A is *p,* then the frequency of the *AA* genotype is $p \times p$ or p^2. If the frequency of *a* is *q,* then the frequency of the *aa* genotype

is q × q $q \times q$ or q 2 q^2. Finally, the frequency of the *Aa* genotype is 2*pq*. These relationships are summarized here:

Frequency of A A = p 2 Frequency of A

$$\text{Frequency of } AA = p^2$$
$$\text{Frequency of } Aa = 2pq$$
$$\text{Frequency of } aa = q^2$$

Because there are no other genotypes in the population, the genotype frequencies must also add to 1 (or 100%). Therefore, we can write the following equation:

p 2 + 2 p q + q 2 = 1

$$p^2 + 2pq + q^2 = 1$$

These relationships are summarized

in TABLE 43.2.

Alleles	*A*	*a*	
Allele frequencies	*p*	*q*	
Genotypes	*AA*	*Aa*	*aa*
Genotype frequencies	p 2 p^2	2pq	q 2 q^2

TABLE 43.2 Relationship Between Allele and Genotype Frequencies Under the Hardy–Weinberg Equilibrium

The relationship between allele and genotype frequencies when a population is in Hardy–Weinberg equilibrium can also be shown visually as shown in FIGURE 43.12. In this figure, the allele frequencies in the population are shown along the side and across the top. The genotype frequencies are indicated by the area

of the squares. So, we see that the area of the square *AA* is p × p $p \times p$ or p 2 p^2; the area of the square *aa* is q × q $q \times q$ or q 2 q^2; and the area of the square *Aa* is *pq,* but because there are two *Aa* squares, the total area is 2*pq*.

FIGURE 43.12 Visual relationship between allele and genotype frequencies under the Hardy–Weinberg equilibrium

This figure shows the frequency of *A* and *a* by the length along the side or top, and the frequency of the three possible genotypes by the area of the squares.

Not only does the Hardy–Weinberg

relation predict genotype frequency from allele frequencies, but it works in reverse too: genotype frequencies can be used to determine allele frequencies. Knowing the genotype frequency of *aa,* for example, permits us to calculate allele frequencies. Let's return to our pea example. In that case, we found that 9% of the population has genotype *aa*. Therefore,

p 2 = 0.09 p = p 2 = 0.09 = 0.3

$$p^2 = 0.09$$

$$p = \sqrt{p^2} = \sqrt{0.09} = 0.3$$

And, because

p + q = 1 $p + q = 1$

then

$$p = 1 - q = 1 - 0.3 = 0.7$$

$p = 1 - q = 1 - 0.3 = 0.7$

We can also illustrate the relationship between allele and genotype frequencies by the graph shown in **FIGURE 43.13**. In this graph, allele frequencies are shown on the *x*-axis along the bottom. Genotype frequencies are plotted on the *y*-axis; and the three colored lines represent the frequency of the three genotypes *AA, Aa,* and *aa* for all allele frequencies.

FIGURE 43.13 Graphical relationship between allele and genotype frequencies under the Hardy–

Weinberg equilibrium

This graph shows the frequency of *A* and *a* along the horizontal *x*-axis, the genotype frequency along the vertical *y*-axis, and the resulting three genotype frequencies for all allele frequencies by the colored lines.

For example, if no *a* alleles are present, then $q = 0$ $q = 0$. This is the far right side of the *x*-axis. At this point along the graph, we can see that $p = 1$ $p = 1$. This makes sense, as $p + q = 1$ $p + q = 1$. To find the genotype frequencies, we look at the colored lines in the graph along the line where $p = 1$ $p = 1$ and $q = 0$

$q = 0$ (far right side of the graph). Along this line, we see that the blue line representing the frequency of *AA* is at 1, and the red line representing the frequency of *aa* and the purple line representing the frequency of *Aa* are both at 0. In other words, when there are no *a* alleles, the frequency of *AA* is 1, the frequency of *Aa* is 0, and the frequency of a a $= 0$ $aa = 0$.

The graph in Figure 43.13 works in reverse as well: we can use it to determine allele frequencies given a set of genotype frequencies. For example, the purple line represents the frequency of heterozygotes *Aa*. When the purple line is 0.5, we can read the corresponding place along

the x-axis to determine the allele frequencies. At this place, we find that the allele frequencies for p and q are both 0.5.

Note that these relationships hold only if the Hardy–Weinberg conditions are met. If not, then we cannot figure out genotype frequencies from allele frequencies. "Analyzing Statistics and Data: The Hardy–Weinberg Equilibrium" reviews the math and provides a practice problem.

ANALYZING STATISTICS AND DATA

The Hardy–Weinberg Equilibrium

The Hardy–Weinberg equilibrium is a method used to compare allele and genotype frequencies to determine if the process of evolution has or has not occurred. There are five conditions that must be in place in order for allele frequencies not to change over time, and evolution not to occur: selection is not operating, there is no genetic drift, there is no migration, there is no mutation, and there is random mating. If these conditions are met, then the population being examined is at Hardy–Weinberg equilibrium. If the conditions are not met, then the population is not at Hardy–Weinberg equilibrium. When populations are at Hardy–Weinberg equilibrium, it is possible to calculate

genotype frequencies from allele frequencies, and allele frequencies from genotype frequencies.

The equations used to determine if a population is at Hardy–Weinberg equilibrium are:

$$p + q = 1 \text{ and } p^2 + 2pq + q^2 = 1$$

$p+q = 1 \text{ and } p^2 + 2pq + q^2 = 1$

where:

p is the dominant allele frequency *A*

q is the recessive allele frequency *a*

p^2 is the genotype frequency *AA*

2*pq* is the genotype frequency *Aa,* and

q^2 is the genotype frequency *aa*

PRACTICE THE SKILL

A small population of 50 rabbits was found on an island a wcentury ago. Scientists discovered the rabbits had two alleles for ear type, *A* for straight ears and *a* for floppy ears. Imagine that we know that the allele frequency of *A* was 0.6. The scientists have monitored the island throughout the years as the population of rabbits increased to 10,000 and have noted that there are 1600 floppy-eared *aa* rabbits in the present day. With this information, determine the allele and genotype frequencies for each time period and interpret whether the frequencies of the alleles *A* and *a* changed over this time period.

Our goal is to compare all the allele and genotype frequencies. We have the frequency for the dominant allele, *A,* and

can determine the allele frequency of the recessive allele, *a,* using the following equation:

$$p + q = 1 \; 0.6 + q = 1 \; q = 0.4$$

$$p + q = 1$$

$$0.6 + q = 1$$

$$q = 0.4$$

We can use the above values to calculate the genotype frequencies, assuming the population was at Hardy–Weinberg equilibrium.

AA

homozygotes: $p\,2 = (\,0.6\,)\,2 = 0.36$

$$p^2 = (0.6)^2 = 0.36$$

Aa

heterozygotes: $2\,p\,q = 2 \times 0.6 \times 0.4 = 0.48$

$$2pq = 2 \times 0.6 \times 0.4 = 0.48$$

aa

homozygotes: q 2 = (0.4) 2 = 0.16

$q^2 = (0.4)^2 = 0.16$

Now that we have all the frequencies for the first time period, we can calculate the frequencies for the present time period. To begin, we'll calculate the genotype frequency q 2 q^2 for the floppy-eared *aa* homozygous rabbits.

q 2 = frequency of a a = number of a a indi

$q^2 = \text{frequency of } aa = \text{number of } aa \text{ individuals}/$
$\text{total number of individuals} = \frac{1600}{10{,}000} = 0.16$

With this value, we can now solve for the allele frequency of *q* and then *p,* assuming the present-day population is at Hardy–Weinberg equilibrium.

If q 2 = 0.16 then q = q 2 = 0.4

If $q^2 = 0.16$ then $q = \sqrt{q^2} = 0.4$

p + q = 1 $p + q = 1$

$$p + 0.4 = 1$$

$$p = 0.6$$

Calculating the genotype frequencies yields the following:

AA

homozygotes: $p^2 = (0.6)^2 = 0.36$

Aa

heterozygotes: $2pq = 2 \times 0.6 \times 0.4 = 0.48$

Looking at each set of allele and genotype frequencies, we can see that neither has changed over the past century, even with the explosion of the rabbit population's size. Because the allele and genotype frequencies have remained the same, we can conclude

that evolution has not occurred.

	p (A)	q (a)	p^2 (AA)	$2pq$ (Aa)	q^2 (aa)
100 years ago	0.6	0.4	0.36	0.48	0.16
Present day	0.6	0.4	0.36	0.48	0.16

Your Turn

A rare neuromuscular disease is known to be caused by a recessive mutation. The recessive homozygous genotype occurs at a frequency of 1 in 5,000,000. Calculate how many people would be carriers of this recessive allele in an area with a population of 10,000 people, assuming Hardy–Weinberg conditions are met.

The Hardy–Weinberg

Equilibrium as a Null Hypothesis

Recall the definition of evolution: a change in the genetic makeup (allele or genotype frequency) from one generation to the next. Given this definition, it might seem odd that we have spent so much time discussing factors necessary for allele frequencies to stay the same. Why study the Hardy–Weinberg equilibrium at all?

The Hardy–Weinberg equilibrium not only provides a means of converting between allele and genotype frequencies but also serves as a null hypothesis for evolutionary studies.

We discussed null hypotheses in Module 0. In science, we start by making observations of some aspect of the natural world. Observations often lead to questions. Scientists then propose a hypothesis, or a tentative answer to the question or explanation of what they observe. Hypotheses are useful because they allow us to make predictions that can be tested by experiments or additional observations.

Often, it is also useful to also propose a null hypothesis, which is a hypothesis that states that nothing is occurring. For example, if the researcher performs a treatment or changes conditions in some way, the

null hypothesis states that the treatment or change has no effect at all on whatever is being studied. In evolutionary biology, the Hardy–Weinberg equilibrium can serve as a null hypothesis. It states that the five mechanisms of evolution are not acting on the population. In essence, it proposes that nothing interesting is happening in a population from an evolutionary viewpoint.

By contrast, when we find a population whose allele or genotype frequencies are not in Hardy–Weinberg equilibrium, we can infer that evolution has occurred in that population. In other words, we can reject the null hypothesis that

evolution is not occurring, which in turn supports the alternative hypothesis that evolution is occurring. With further study of the population, we can consider, for the gene in question, whether the population is subject to one of the five mechanisms of evolution: natural selection, genetic drift, migration, mutation, or nonrandom mating. Thus, the Hardy–Weinberg equilibrium gives us a baseline from which to explore the evolutionary processes affecting populations.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be familiar with the

Hardy–Weinberg equilibrium and its use. Make sure you are able to use it to test whether a population is undergoing evolution. This may be done by noting if allele and genotype frequencies of a population change from time 1 to time 2, or by determining whether the Hardy–Weinberg equilibrium conditions are met.

✓ Concept Check

8. **Describe** how you would determine genotype frequencies given two alleles at frequencies p and q for a population at Hardy–Weinberg equilibrium.

9. **Describe** what it means if a population is not in Hardy–Weinberg

equilibrium.

Module 43 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Choose one of the five mechanisms of evolution discussed in the module and **describe** how that mechanism can lead to a change in allele or genotype frequencies in a population over time or both.

LG 43.1 Evolution is a change in the genetic makeup of a population over time.

- Genetic variation can be measured by allele frequency and genotype frequency. Page 600
- Evolution is a change in the frequency of alleles or genotypes in a population over time. Page 600
- Populations, not individuals, evolve. Page 601

LG 43.2 There are five mechanisms of evolution.

- Natural selection leads to a decrease in frequency of a harmful allele and an increase in

frequency of a beneficial allele. Page 602

- Natural selection is the only mechanism of evolution that results in adaptations. Page 602
- Genetic drift is a random change in allele frequency change. Page 603
- Genetic drift acts more strongly in small populations than in large ones. Page 603
- Two forms of genetic drift are a population bottleneck and founder effect. Page 603
- Migration involves the movement of individuals and alleles between populations and tends to have a homogenizing effect among populations. Page 604

- Mutation is the ultimate source of variation, but it also can change allele frequencies on its own. Page 606
- Nonrandom mating occurs when individuals choose mates based on their genotypes. Page 606
- Inbreeding is a form of nonrandom mating. Page 607
- Nonrandom mating, such as inbreeding, changes genotype frequencies, but does not change allele frequencies. Page 607

LG 43.3 The Hardy–Weinberg equilibrium occurs when the genetic makeup of a population does not change over time.

- When certain conditions are met,

allele and genotype frequencies do not change, a state called the Hardy–Weinberg equilibrium. Page 607

- The five conditions of the Hardy–Weinberg equilibrium are that the population experiences no selection, no chance events due to small population size, no migration, no mutation, and random mating. Page 608
- The Hardy–Weinberg equilibrium allows allele frequencies and genotype frequencies to be calculated from each other. Page 609
- By determining whether a population is in Hardy–Weinberg equilibrium, we can determine

whether evolution is occurring in a population. Page 610

Review Questions

1. At the genetic level, evolution is

   A. a change in fitness over time.
   B. a change in the number of individuals in a population over time.
   C. a change in the frequency of

an allele or genotype over time.

D. an increase in fitness over time.

2. If there is inbreeding in a population, which would you expect to observe with respect to allele frequencies and genotype frequencies?

A. Allele frequencies would change, and genotype frequencies would change.
B. Allele frequencies would change, and genotype frequencies would not change.
C. Allele frequencies would not change, and genotype frequencies would change.

D. Allele frequencies would not change, and genotype frequencies would not change.

3. A gene in a diploid species has five different alleles. In any one population, the allele frequencies of all five alleles must add up to

A. one.
B. two.
C. five.
D. ten.

4. If there are 100 individuals in a population and 20 are homozygous for *B,* 60 are heterozygous, and 20 are homozygous for *b,* what is the allele frequency of *B?*

A. 0.20

B. 0.40

C. 0.50

D. 0.80

5. If a gene has two alleles, and allele *A* has a frequency of 83%, then allele *a* has a frequency of

A. 17%.

B. 117%.

C. 41.5%.

D. 7%.

6. What does the term $2pq$ represent in the Hardy–Weinberg relation?

A. The frequency of homozygous dominant individuals

B. The frequency of heterozygotes

C. The frequency of homozygous

recessive individuals

D. The frequency of deleterious mutations

7. The only mechanism of evolution that leads to adaptations is

A. natural selection.

B. genetic drift.

C. migration.

D. nonrandom mating.

Module 43 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

1. Which would tend to increase genetic similarity between two geographically separated populations of the same species?

   A. Genetic bottlenecks
   B. Mutation
   C. Migration
   D. Genetic drift

2. Scientists observed a population of lizards living on a small, forested island in the Pacific Ocean for many consecutive years. All the lizards observed were the same light-green color, matching many of the plants in

the forest. In the middle of the observation period, a volcanic eruption covered much of the island with black volcanic rock. In the years following the eruption, the scientists began to observe that lizards living on the volcanic rock tended to be darker in color than lizards living in the surrounding forest, which retained their light-green coloring. Which provides the best explanation for the observation?

A. A random mutation that results in darker color increased in frequency after the eruption.
B. The lizards needed to adapt to the volcanic rock, so they

mutated a gene that controls color.

C. Light-green lizards migrated from another island and colonized the forest.

D. A genetic bottleneck increased the frequency of a mutation that controls color.

Use the following information to answer questions 3 and 4.

In 1983, a new housing development was constructed in a forested region that provides habitat for timber rattlesnakes. The construction of the buildings and associated major roads resulted in a small patch of forest becoming physically disconnected from the remaining forest. Heavily

trafficked roads and highways create barriers to movement for timber rattlesnakes because the snakes cross roads slowly and therefore are frequently killed by cars.

Every 5 years between 1985 and 2020, a researcher measured the frequency of an allele that is unrelated to fitness in timber rattlesnakes. The researcher took samples both from the isolated small patch of forest and from the larger forest that the small patch was previously connected to. These allele frequencies were compared to the frequency of the mutant allele measured in the forest in 1980, before construction of the housing development. The data are

plotted in the following figure.

1. Which statement is best supported by the data?

   A. The isolated forest patch population is in Hardy–Weinberg equilibrium.
   B. Migration between the large forest and the isolated forest patch maintains allele frequencies at a constant level in the large forest.
   C. In the isolated forest patch, new alleles arose for the gene whose allele frequencies were measured.
   D. The isolated forest patch has a

smaller population of timber rattlesnakes than the large forest does.

2. Which would be most likely to occur if the housing development is removed and the isolated patch becomes reconnected to the larger forest?

   A. Allele frequencies in the area that is now the isolated patch would become similar to allele frequencies in the forest.
   B. Timber rattlesnakes from the area that is now the isolated patch would migrate and replace the snakes in the forest.
   C. Timber rattlesnakes in the area

that is now the isolated patch would go extinct.

D. The allele frequencies in the whole population would become the average of the allele frequencies in the patch and the allele frequencies in the forest.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Yellow monkeyflower (*Mumulus guttatus*) is an annual plant that is

sometimes able to grow in soil contaminated with copper, including soil near copper mines. A scientist hypothesized that the GSTCuGST^{Cu} allele of the gene encoding glutathione S-transferase (GST) might cause resistance to environmental copper, but that plants homozygous for GST + GST^{+} alleles would not grow well in the presence of copper in the soil.

The scientist planted populations of *M. guttatus* in a laboratory greenhouse under two growth treatments. In treatment 1, a population was grown in soil contaminated with a level of copper similar to what is observed near

copper mines. In treatment 2, the population was grown in soil without excess copper. The populations in both treatments were started with 50 GST+/GST+ $50\ GST^{+}/GST^{+}$ plants, 100 GST+/GSTCu $100\ GST^{+}/GST^{Cu}$ plants, and 50 GSTCu/GSTCu $50\ GST^{Cu}/GST^{Cu}$ plants. Every generation, the scientist allowed the plants to cross randomly within each treatment population. For each treatment, the scientist collected the seeds from the flowers in the population and planted 100 new plants under the same treatment conditions. The scientist measured the frequency of the GST+ GST^{+} and GSTCu GST^{Cu} alleles every generation for five generations and

obtained the data shown in the table.

	Treatment 1 (copper contamination)		Treatment 2 (no excess copper)	
Generation	Frequency of GST + GST^{+} allele	Frequency of GSTCu GST^{Cu} allele	Frequency of GST + GST^{+} allele	Frequency of GSTCu GST^{Cu} allele
1	0.50	0.50	0.50	0.50
2	0.42	0.58	0.44	0.56
3	0.37	0.63	0.41	0.59
4	0.31	0.69	0.43	0.57
5	0.28	0.72	0.38	0.62

a. On a single graph, **plot** the frequencies of the GST + GST^{+} and GSTCu GST^{Cu} alleles in each generation for both treatments.
b. **Identify** the null hypothesis and the control in this experiment.
c. **Determine** whether the data

obtained from the experiment do or do not support the scientist's hypothesis.

d. **Make a claim** to explain the data obtained from treatment 2. Propose an additional experiment that would test your claim.

Module 44

Evidence of Common Ancestry and Evolution

LEARNING GOALS

- **LG 44.1 Homologous traits provide evidence for common ancestry.**
- **LG 44.2 Vestigial structures provide a window on the past.**
- **LG 44.3 Fossils provide direct evidence of past life.**
- **LG 44.4 The distribution of organisms on earth sheds light on evolutionary history.**

In the last few modules, we have discussed evolution, which is a change in the genetic makeup of a population over time. We have seen how to measure genetic variation by calculating allele and genotype frequencies. We can follow these frequencies over time to see if they change or stay the same. We have also discussed the five mechanisms that bring about evolutionary change from one generation to the next. These mechanisms are natural selection, genetic drift, migration, mutation, and nonrandom mating. All these mechanisms lead to a change in the allele frequency, genotype frequency, or both in populations over time. However, only natural selection leads

to adaptations, the fit between an organism and its environment.

Up to this point, we have focused on the genetic basis of evolution and used mathematical models to show how it occurs. Can we see any evidence of evolution? The answer is a resounding yes. In this module, we will see that evidence of evolution is literally all around us—in the traits of organisms, in the fossil record, and even in the distribution of species on Earth. Each one of these teaches us something about the evolutionary history of life on Earth, and therefore provides strong evidence for evolution.

FOCUS ON THE BIG

PREP FOR THE AP® EXAM

EVOLUTION: Look for examples of structural, functional, and molecular data that provide evidence of evolution.

44.1 Homologous traits provide evidence for common ancestry

Different species sometimes have traits in common. As we saw in Module 41, convergent evolution can account for some of these similarities; the trait may have evolved independently in the two groups as an adaptation to similar environments. Alternatively, some of these similarities reflect common ancestry; the trait may have been present in the common ancestor of the two groups and retained over time. Traits that are similar because of convergent evolution are analogous. Traits that are similar because of descent from a common ancestor are homologous, or a homology among descendant species. Homologous traits provide evidence

for evolution. They show us what common ancestors might have looked like and help us to group species based on their evolutionary history.

In this section, we will look at various traits among organisms that are shared because of descent from a common ancestor. We will examine many different types of traits, including anatomical, cellular, and molecular traits.

Anatomical Traits

Let's consider some anatomical traits that were present in a common ancestor and retained over time. These anatomical traits are considered **morphological**

homologies because they are similarities based on shared ancestry (homologies) and they are structural (morphological). Mammals, birds, and reptiles all have a water-tight egg called an amniotic egg. This trait is so important that mammals, birds, and reptiles are collectively called amniotes. The amniotic egg allows these groups to reproduce in dry environments, away from water. Why do these different groups all share this trait? Multiple lines of evidence suggest that it was present in the common ancestor of these groups and retained over time, so that all descendants of this ancestor now have the trait.

We can visualize what happened using a phylogenetic tree like the ones we discussed in Module 40. In **FIGURE 44.1**, time runs from left to right, and living organisms are placed at the tips of the trees. Note that the amniotic egg evolved at the base, or root, of the tree. All of the descendant species have the trait because it was present in their common ancestor.

FIGURE 44.1 Descent from a common ancestor

The amniotic egg is a homologous trait shared by reptiles, birds, and mammals. It evolved once in the common ancestor of these animals and was retained over time.

Let's consider another example—our four limbs. This trait evolved in the first vertebrates to leave the water and move about on land. Amphibians such as frogs and salamanders, reptiles such as turtles and lizards, birds, and mammals all show remarkable anatomical similarities in the structure of these limbs. In fact, this structure is so important that these groups are collectively called tretrapods, which means "four-footed animals." This basic structure has been retained in all the descendants of this organism. It has also been modified over time, so that some animals walk on four legs, while others walk on two legs. Still others—such as birds and bats—fly; in these

cases, two of the four limbs have evolved into wings, while the remaining two are legs. In marine mammals, the forelimbs have been modified into fins. In spite of their superficial differences, these structures are all variations on the same theme. The fact that they all share the same anatomical structure provides evidence that they evolved from a common ancestor with this structure.

We can illustrate the evolution of four limbs using an evolutionary tree, as shown in **FIGURE 44.2**. In this tree, time runs from left to right. The trait "walking legs" evolved at the base of the tree, on the left. All of the

descendant species, including amphibians, reptiles, birds, and mammals have this trait or a modification of this trait.

FIGURE 44.2 An evolutionary tree showing the origin of walking legs

The trait “walking legs” is a homology shared by amphibians, reptiles, birds, and mammals. It evolved once in the common ancestor of these animals and was retained over time.

Cellular Traits

When we think of traits, we often think of anatomical structures. However, we can also consider

cellular structures. Humans, other animals, plants, fungi, and many other groups or organisms all have cells with a nucleus. Hence, we are part of a group called eukaryotes, from the Greek *eu* meaning "true" and *karyon* meaning "nucleus." The cells of these organisms share traits in addition to a nucleus, including a cell membrane; mitochondria; and membrane-bound organelles such as the endoplasmic reticulum, Golgi apparatus, and vesicles, as shown in **FIGURE 44.3**. Genetically, they all have one or more linear chromosomes and genes that contain exons, which are expressed, and introns, which are intervening sequences that are spliced out and

therefore not expressed. Multiple lines of evidence demonstrate that these traits were present in the first eukaryotic cell and so are homologous traits in all eukaryotes.

FIGURE 44.3 Shared cellular traits in eukaryotes

Eukaryotic cells have a nucleus, mitochondria, and membrane-bound organelles such as the endoplasmic reticulum and Golgi apparatus, all of which were present in their common ancestor.

Finally, we can consider traits shared by all living organisms, including eukaryotes and prokaryotes, such as

bacteria and archaea. These universal traits include the ability to grow and reproduce, evolve, respond to the environment, maintain homeostasis, and harness energy. These were certainly present in the universal common ancestor of all living things and, collectively, provide a way to think about the definition of life itself.

Some of these universal cellular traits are structural, such as a cell membrane enclosing the cell, cytoplasm making up the cell interior, genetic material in the form of DNA, and ribosomes that synthesize proteins from RNA. Some are processes, such as metabolic reactions that produce ATP, the ability

to maintain homeostasis, a genetic code in which three nucleotides specify a single amino acid during translation, and the capacity for evolution over time. These structural and functional traits are conserved in all organisms and provide evidence for the relatedness of organisms across all three domains of life.

Molecular Traits

Up to this point, we have considered anatomical traits, such as the amniotic egg and walking legs, as well as cellular structures, such as the cell membrane, nucleus, and ribosomes. We can also consider molecular traits. The nucleotide sequence of DNA and

RNA, and the amino acid sequence of proteins are molecular traits that can be compared between two species. These too can provide evidence for evolution and common ancestry.

The extent of genetic difference, or genetic divergence, between two species is a function of the time they have been genetically isolated from each other. The longer they have been apart, the greater the opportunity for mutations to occur in each population and for those mutations to increase in frequency through the population over time. This correlation between the time for which two species have been evolutionarily separated and the amount of genetic divergence

between them is known as the **molecular clock**.

The slowest molecular clock on record belongs to the histone genes, which encode the proteins around which DNA is wrapped to form chromatin (see Module 31). These proteins are exceptionally similar in all organisms; only two amino acids in a chain of about 100 are different in plant and animal histones. Plants and animals last shared a common ancestor more than 1 billion years ago. Despite this lengthy span of time, the histones have hardly changed at all. In other words, the histone genes are evolutionarily conserved in distantly related species. Almost any

amino acid change fatally disrupts the histone protein, preventing it from carrying out its proper function. Natural selection against these variants has thus been extremely effective in eliminating just about every amino acid–changing histone mutation over time. As a consequence, the histone molecular clock is breathtakingly slow.

The histone gene is a homologous trait among all eukaryotic cells, present in the common ancestor and retained, essentially unchanged, in the descendant species. There are many examples of shared genes between groups that were present in a common ancestor and thus

homologous in these groups. Many of these genes change more rapidly than the histone genes, but they retain enough similarity that they are unmistakably homologous, just like the leg of a lizard, arm of a human, wing of a bird, and flipper of a whale.

Some examples of homologous genes include *Pax6* in vertebrates and related genes in other organisms. Recall from Module 36 that *Pax6* encodes a transcription factor that controls eye development in a wide range of species. This gene evolved at least 500 million years ago and has been conserved over time. This means that it has changed very little and has retained its function over the

course of evolution. Similarly, hemoglobin, which binds oxygen in your red blood cells, is encoded by an ancient gene that is present in many different species, including animals, plants, and fungi.

✓ Concept Check

1. **Describe** a homologous trait.

2. **Identify** two examples of homologous traits.

3. **Identify** three homologous traits shared by all eukaryotes.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022
BFW High School Publishers

44.2 Vestigial structures provide a window on the past

In addition to homologous traits shared by different species, we can also look at *vestigial structures*. **Vestigial structures** are traits that were once useful and functional but are no longer and so tend to be reduced in size or function. The presence of a trait in a reduced or nonfunctional structure in an organism suggests that it is a vestigial structure. These traits give us a

window on the past.

Consider the hip bone in whales. Whales and other marine mammals evolved from land-based mammals that moved about on four legs. When they returned to the water, the legs were no longer useful and might have even been detrimental to moving about in the water. Over time, hind legs that were reduced in size were likely selected for and therefore became more common in the population. Now, they are no longer present at all. However, the hip bone to which the limbs attach is small but still present, providing one piece of evidence that these animals once walked on land with hind legs, like

other mammals.

A vestigial hip bone of a whale is shown in **FIGURE 44.4**. Note that vestigial structures are examples of morphological homologies. The vestigial hip bone of a whale is homologous to the larger and more functional hip bone of other vertebrate animals that move about on land.

FIGURE 44.4 Vestigial structure

The hip bone in a whale is a good example of a vestigial structure, one that was once functional, but now is much reduced in size.

One of the most famous examples of a vestigial structure is the appendix, a short appendage or blind sac of the gastrointestinal tract in humans and other mammals. Although the appendix has no clear function in humans, it may play a minor role in the immune system. The appendix can become infected when partially digested material enters or blocks it, resulting in appendicitis. Unless the infected appendix is removed, it can burst, releasing gut contents into the abdominal cavity. Such a rupture can be life threatening.

Why then do we have an appendix? Charles Darwin put forth a hypothesis explaining how the appendix might

have evolved to take on its current form in humans. He suggested that in the ancestors of modern humans, this part of the gut harbored bacteria that helped to break down plant material such as cellulose. However, as their diet became less reliant on plant material, this part of the gut no longer served a function. As a result, selection on its form and function relaxed and it became smaller and lost its function over time. Today, what remains of this structure is the appendix.

Other vestigial structures, such as small eyes in cave-dwelling animals and rudimentary wings in flightless birds and insects, provide an

illuminating window into the past and strong evidence for evolution.

Just like an anatomical structure, genes that encode proteins can also lose function over time. A pseudogene is a gene that was once functional but is no longer. In other words, the gene used to produce a protein product, but no longer does, so it is not expressed. Pseudogenes are the genetic equivalent of the whale pelvis or the human appendix, a genetic remnant. Because all mutations in a pseudogene are by definition neutral—there is no function for a mutation to disrupt, so a mutation is neither harmful nor beneficial—we expect to see a

pseudogene's molecular clock tick at a very fast rate. In the histone genes, virtually all mutations are selected against, slowing the rate of evolution. In pseudogenes, no such selection against harmful variants is operating.

✓ Concept Check

4. **Describe** what a vestigial structure is.

5. **Identify** two examples of vestigial structures.

44.3 Fossils provide direct evidence of past life

The anatomical, cellular, and molecular traits of living organisms are useful ways to learn about evolutionary history, but the information is indirect. Direct evidence from the past comes from *fossils*. **Fossils** are the remains of once-living organisms. Fossils provide unique information about the past that we would otherwise not know. However, the fossil record is an incomplete record of the past because it preserves only a small fraction of all the organisms that have ever lived. In this section, we will discuss how fossils form, consider the unique

information fossils provide, and learn about how fossils are dated.

The Fossil Record

Fossilization is the process by which fossils form. Fossilization begins with burial. For example, a clam that dies on the seafloor may be quickly covered by sand, or a leaf that falls to the forest floor may be covered in mud during a flood event. Through time, accumulating sediments from sand, mud, or soil harden into sedimentary rocks, such as those exposed so dramatically in the walls of the Grand Canyon, shown in **FIGURE 44.5**. If the remains of an organism are not buried, they are

eventually recycled by biological and physical processes as discussed in Module 1, and no fossil forms.

FIGURE 44.5 A record of Earth's history at the Grand Canyon

Erosion has exposed layers of sedimentary rock that record Earth's history.

The fossil record should not be thought of as a complete encyclopedia of everything that ever walked, crawled, or swam across our planet's surface. In general, the fossil record of marine life is more complete than that for land-dwelling creatures because sediments in

marine habitats are more likely to accumulate and become rock. Because of the way fossils form, organisms such as trees and elks living high in the Rocky Mountains have a low probability of fossilization, whereas clams and corals on the shallow seafloor are commonly buried and become fossils.

Biological factors also limit the fossil record. Most fossils preserve just the hard parts of organisms—those features that resist decay after death. For animals, this usually means hard skeletons. Clams and snails that have shells also have excellent fossil records. More than 80% of the clam species found today along California's

coast also occur as fossils in sediments deposited during the past million years. In contrast, nematodes, tiny worms that may be the most abundant animals on Earth, have no hard skeletons and are not well represented in the fossil record. The wood and pollen of plants, which are made in part of decay-resistant organic compounds, enter the fossil record far more commonly than do flowers. And, among unicellular organisms, the skeleton-forming diatoms, foraminifera, and radiolarians photographed in **FIGURE 44.6** have exceptionally good fossil records, whereas unicellular organisms without hard parts, like amoebas, are underrepresented.

FIGURE 44.6 Unicellular organisms with skeletons

Diatoms (a), foraminifera (b), and radiolarians (c) all have hard skeletons, which preserve well as fossils.

Together, then, the environment and properties of organisms influence the probability that an ancient species will be represented in the fossil record. Organisms that live in environments where burial in sediment is likely are more often preserved than organisms that live in environments where burial in sediment is unlikely. And organisms with hard parts such as skeletons or

shells are more likely to be represented in the fossil record than organisms with only soft parts.

In some cases, organisms that lack hard parts can also leave a fossil record. Some animals leave tracks and trails as they move about or burrow into sediments. These fossils of trails, rather than body parts, are called trace fossils. Trace fossils range from dinosaur tracks like those shown in **FIGURE 44.7**, to the feeding trails of snails and trilobites. In essence, they preserve a record of both anatomy and behavior.

FIGURE 44.7 Trace fossils

These footprints in 150-million-year-old rocks record both the structure and the

behavior of the dinosaurs that made them.

Organisms can also leave behind molecular fossils. Most biological molecules decay quickly after death. Proteins and DNA, for example, generally break down before they can be preserved, although, remarkably, the genome of an early human species known as Neanderthal has been pieced together from DNA in 40,000-year-old bones. Other molecules, especially lipids like cholesterol, are more resistant to decomposition. Sterols, bacterial lipids, and some pigment molecules can accumulate in sedimentary rocks. Scientists can study molecular fossils

for organisms such as bacteria and single-celled eukaryotes, which rarely form conventional fossils.

Sometimes unusual conditions preserve fossils of unexpected quality, including animals without shells, delicate flowers or mushrooms, fragile seaweeds or bacteria, and even the embryos of plants and animals. For example, during the Cambrian Period (541–485 million years ago), a sedimentary rock formation called the Burgess Shale accumulated on a relatively deep seafloor covering what is now British Columbia. Waters just above the basin floor contained little or no oxygen. Thus, when mud swept into the basin, entombed animals

were sealed off from scavengers, disruptive burrowing activity, and even bacterial decay. For this reason, the Burgess Shale preserves remarkable fossils of marine life over 500 million years ago during the initial diversification of animals, one of which is shown in **FIGURE 44.8**.

FIGURE 44.8 A Burgess Shale fossil

This fossil is *Opabinia regalis,* an extinct early relative of the arthropods, from the 505-million-year-old Burgess Shale.

In general, the fossil record preserves some aspects of biological history well and others poorly. Fossils provide a good sense of how the forms, functions, and diversity of skeletonized animals have changed

over the past 500 million years. The same is true for land plants and unicellular organisms that form mineralized skeletons. Collectively, these fossils shed light on major patterns of evolution and diversity change through time; their geographic distributions record the movements of continents over millions of years; and the radiations and extinctions they document show how life responds to environmental change, both gradual and catastrophic.

Unique Information from Fossils

Although the fossil record is

incomplete, there is information we can learn from fossils that we would not otherwise know or even be able to guess. Not only do fossils record past life, but they also provide our only direct record of extinct species. The evolutionary tree shown in Figures 44.1 and 44.2 contain a great deal of information, but they don't give a hint about dinosaurs. Fossils demonstrate that dinosaurs once roamed Earth.

Fossils also give us direct evidence of transitional forms, sometimes called missing links, between modern groups of organisms. In 1861, just two years after publication of *On the Origin of Species,* German quarry workers discovered a remarkable

fossil that remains one of paleontology's most famous examples of a form that is transitional between two groups. *Archaeopteryx lithographica,* shown in **FIGURE 44.9**, lived 150 million years ago. Its skeleton shares many characters with a group of small, agile dinosaurs, but several features—its pelvis; its braincase; and, especially, its winglike forearms—are distinctly birdlike. Spectacularly, the fossils preserve evidence of feathers. *Archaeopteryx* clearly suggests a close relationship between birds and dinosaurs. In fact, today we know that modern birds are descended from a group of dinosaurs and are therefore considered living dinosaurs.

FIGURE 44.9 *Archaeopteryx*

This fossil has features of dinosaurs and modern birds, including feathers, indicating that birds and dinosaurs are closely related.

Tiktaalik roseae is another famous fossil of a transitional form, in this case between fish and amphibians. The fossil is about 370 million years old and it documents the colonization of land by vertebrates. All land vertebrates, from amphibians to mammals, are descended from a common ancestral fish. *Tiktaalik* had fins, gills, and scales like other fish of its day, but its skull was flattened, more like that of a crocodile than a fish, and it had a functional neck and

ribs that could support its body—features today found only in tetrapods. Along with many other fossils, *Tiktaalik* captures a key moment in the evolutionary transition from water to land. In "Practicing Science 44.1: Do fossils bridge the evolutionary gap between fish and tetrapod vertebrates?" we describe *Tiktaalik* in more detail and point out structures that indicate that it is a transitional form between fish and the first land-based, walking vertebrates.

Practicing Science 44.1

Do fossils bridge the evolutionary gap between fish

and tetrapod vertebrates?

PREP FOR THE AP® EXAM

Background Anatomical and molecular traits of living animals indicate that fish are the closest relatives of four-legged land vertebrates.

Hypothesis Land vertebrates evolved from fish by modification of the skeleton and internal organs that made it possible for them to live on land.

Observation Fossil skeletons 390 to 360 million years old show a mix of features seen in living fishes and amphibians. Older fossils have fins, fishlike heads, and gills, whereas younger fossils have weight-bearing legs, skulls with jaws able to grab prey, and ribs that help ventilate lungs. Paleontologists

predicted that key intermediate fossils would be preserved in 380- to 370-million-year-old rocks.

In 2004, Edward Daeschler, Neil Shubin, and Farish Jenkins discovered the remarkable fossil *Tiktaalik* in rocks laid down by a meandering stream of just the right age. *Tiktaalik* had fins, scales, and gills like fishes, but an amphibian-like skull and a true neck (which fishes lack). Its limbs preserve wrist bones and fingers broadly similar to those in tetrapod vertebrates. Even so, as the reconstruction shows, its forelimbs were not completely adapted for movement on land.

Conclusion Fossils provide evidence that tetrapod vertebrates evolved from

fish by the developmental modification of limbs, skulls, and other features.

Follow-up Work Research into the genetics of vertebrate development shows that the limbs of fish and amphibians are shaped by similar patterns of gene expression, providing further support for the connection between the two groups.

SOURCE
Daeschler, E. B., N. H. Shubin, and F. A. Jenkins Jr. 2006. "A Devonian Tetrapod-like Fish and the Evolution of the Tetrapod Body Plan." *Nature* 440:757–763.

AP® PRACTICE QUESTION

In newspaper articles, *Tiktaalik* was proclaimed as the missing link between fish and tetrapods. The figure to the left correctly shows *Tiktaalik* having come

into existence “in between” fish and tetrapods. This conclusion is supported by the fossil record, which shows early fish fossils in older rocks than those in which *Tiktaalik* were found, and tetrapod fossils in younger rocks than those in which *Tiktaalik* were found. However, the term “missing link” and the chronological representation of the fossils can lead to the misconception that modern fish gave rise to *Tiktaalik,* which subsequentially gave rise to modern tetrapods and that there is an unbroken chain that connects modern forms.

a. Explain the evolutionary relationship *Tiktaalik* has with fish and tetrapods, and the reason “missing link” may lead to misunderstandings about evolution.

b. Place the following statements in the correct order that they most likely occurred:

- The group possessing the flattened head and the true neck split into two groups, with one of them continuing to evolve into *Tiktaalik*.
- A common ancestor to all three groups existed, possessing fishlike traits.
- The second group from the second split continued to evolve into the present-day tetrapods.
- The second group developed a flattened head and a true neck.
- The common ancestor split into two groups, one of which continued to evolve into the present-day fishes.

Fossils also place evolutionary events within the context of Earth's dynamic environmental history. Again, dinosaurs illustrate the point. Geologic evidence from several continents suggests that a large meteorite triggered drastic changes in the global environment 66 million years ago, leading to the extinction of dinosaurs (other than birds). In fact, five times in the past, large environmental disturbances sharply decreased Earth's biological diversity. These events, called mass extinctions, have played a major role in shaping the course of evolution, and we know about them from the fossil record.

Dating Fossils

How do we know the age of a fossil? Beginning in the nineteenth century, geologists recognized that the types of fossils found in layers of rock change in a regular fashion from the bottom of a sedimentary rock formation to its top. As more of Earth's surface was mapped and studied, it became clear that certain fossils always occur in layers that lie beneath (and so are older than) layers that contain other species. From these patterns, geologists concluded that fossils mark time in Earth's history. At first, geologists could not explain why fossils changed from one bed to the next, but after Darwin the reason became apparent: fossils record the evolution of life on Earth.

The layers of fossils in sedimentary rocks tell us that some rocks are older than others, but they cannot by themselves provide an absolute age. This information became possible with the discovery of radioactive decay. Radioactive decay makes use of isotopes, variants of an element that differ from one another in terms of the number of neutrons they contain. Many isotopes are unstable and spontaneously break down, ejecting neutrons, electrons, or other particles to form other, more stable isotopes. In the laboratory, scientists can measure how quickly unstable isotopes decay. Then, by measuring the amounts of the unstable isotope and its stable daughter isotope inside

a mineral, they can determine when the mineral formed.

Scientists commonly use the radioactive decay of the isotope **carbon-14**, or 14 C ^{14}C, to date wood and bone, a process called **radiometric dating**. 14 C ^{14}C is an isotope of carbon with eight neutrons and six protons instead of the more stable (and more common) configuration of six neutrons and six protons.

As shown in **FIGURE 44.10**, cosmic rays continually generate neutrons that collide with nitrogen in the atmosphere to form 14 C ^{14}C, much of which is incorporated into

atmospheric carbon dioxide (CO 2) (CO_2). Through photosynthesis, carbon dioxide that contains 14 C ^{14}C is incorporated into wood, and animals incorporate small amounts of 14 C ^{14}C into their tissues when they eat plant material. The unstable 14 C ^{14}C in these tissues begins to break down immediately, losing an electron to form 14 N ^{14}N, a stable isotope of nitrogen. Once the organism dies, 14 C ^{14}C is no longer added, so the clock of radioactive carbon starts to tick. Laboratory measurements indicate that half of the 14 C ^{14}C in a given sample will decay to nitrogen in 5730 years. The **half-life** is the time it takes for an amount of a substance to reach half

its original value. Radioactive half-life is the time it takes for half of the atoms in a given sample of a substance to decay.

FIGURE 44.10 Carbon dating

Scientists can determine the age of relatively young materials such as wood and bone from the amount of 14 C ^{14}C they contain.

The graph in **FIGURE 44.11** shows the decay of 14 C ^{14}C. After 5730 years, 50% of the starting amount remains. After another 5730 years, or 11,460 years in total, half of 50%, or 25%, remains. After another 5730 years, or 17,190 years in total, half of 25%, or

12.5%, remains, and so on.

FIGURE 44.11 Half-life

The half-life of a substance is the time it takes for an amount of a substance to reach half its original amount. In the case of 14 C ^{14}C, the half-life is 5730 years, so half of it remains after every 5730 years.

All isotopes of elements have a unique half-life, which vary in length depending on their stability. Armed with this information, scientists can measure the amount of 14 C ^{14}C in an archaeological sample and, by comparing it to the amount of 14 C ^{14}C in a sample of known age,

determine the age of the sample. The known age of a sample can be based on annual rings in trees, for example, or yearly growth of coral skeletons.

Because its half-life is so short by geologic standards, 14 C ^{14}C is useful only in dating material younger than 50,000 to 60,000 years. Beyond that point, too little 14 C ^{14}C is left in the material to measure accurately. Older geologic materials are commonly dated using the radioactive decay of uranium (U) to lead (Pb) : 238 U (Pb): ^{238}U, which may be incorporated in trace amounts into the minerals of volcanic rocks, breaks down to 206 Pb ^{206}Pb with a half-life of 4.47 billion years; 235 U ^{235}U decays

to 207 Pb ^{207}Pb with a half-life of 704 million years. Calibration of the geologic timescale is based mostly on the ages of volcanic ash found in sedimentary rocks that contain key fossils, as well as volcanic rocks that intrude into, and so are younger than, layers of rock containing fossils. "Analyzing Statistics and Data: Radiometric Dating" reviews how to calculate problems involving half-lives and provides a problem for you to try.

ANALYZING STATISTICS AND DATA

Radiometric Dating

PREP FOR THE AP® EXAM

Fossils are formed when an organism or plant is buried in sediment. Over time and as more layers of sediment are added, the buried material is preserved and replaced by minerals, forming a fossil. The age of a fossil can often be determined using radiometric dating and half-lives. A half-life is the amount of time it takes for a radioactive isotope to decay to the point that half of it remain in a sample. Figure 44.11 shows this explanation graphically.

Scientists use several different radioactive elements to date materials depending on their age. The radioactive decay of carbon-14 is used for organic materials that are 40,000 to 50,000 years old. The half-life of $14\ \mathrm{C}$ $^{14}\mathrm{C}$ is 5730 years. For older rocks or fossils, scientists can use the radioactive decay

of uranium-235, potassium-40, or uranium-238.

PRACTICE THE SKILL

An earthquake in California caused a shift in the layers of a sedimentary rock formation. This shift exposed several young fossil specimens. Scientists wish to determine the age of these fossils using the radioactive decay rate of carbon-14. They have measured the amount of $14\ \mathrm{C}$ $^{14}\mathrm{C}$ in one fossil to be approximately 0.0313 as much as what was in the original atmosphere. Use this information to calculate how many half-lives have occurred and the estimated age of the fossil.

To begin, we know that the $14\ \mathrm{C}$ $^{14}\mathrm{C}$ in the fossil is only a fraction of that found in the original atmosphere, 0.0313 as

much. We can use this number to figure out how many $14\ C$ ^{14}C half-lives have taken place.

One half-life can also be expressed as the fraction $1\ 2$ $\frac{1}{2}$, the decimal 0.5, or the percentage 50%. Two half-lives would then be $1\ 2 \times 1\ 2$ $\frac{1}{2} \times \frac{1}{2}$ or $1\ 4\ ,\quad 0.25\ ,$ $\frac{1}{4}$, 0.25, and 25%. We can continue this way to see how many half-lives it takes to get to the value 0.0313.

$$3 \text{ half-lives: } 1\ 2 \times 1\ 2 \times 1\ 2 = 1\ 8 = 0.125$$

$$3 \text{ half-lives: } \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \frac{1}{8} = 0.125 = 12.5\%$$

$$4 \text{ half-lives: } \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \frac{1}{16} = 0.0625 = 6.25\%$$

$$5 \text{ half-lives: } \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} \times \frac{1}{2} = \frac{1}{32} = 0.0313 = 3.13\%$$

Given the amount of $14\ C$ ^{14}C left in the fossil the scientists discovered is 0.0313, we can see that 5 half-lives have occurred.

Now we can calculate how many years this is to figure out the age of the fossil. $14\ \mathrm{C}$ $^{14}\mathrm{C}$ has a half-life of 5730 years. Each 5730-year period reduces the original amount of $14\ \mathrm{C}$ $^{14}\mathrm{C}$ by 50%. Because we know that 5 half-lives have occurred, we can multiply 5730 years by 5 half-lives to determine the age of the fossil:

$$5 \quad \text{half-lives} \times 5730 \quad \text{years } 1 \quad \text{half-life} = 28$$

$$5\,\text{half-lives} \times \frac{5730\,\text{years}}{1\,\text{half-life}} = 28,650\,\text{years}$$

Using radiometric dating, the fossil is about 28,650 years old.

Your Turn

A new isotope has been discovered to be useful in the radiometric dating of rocks and fossils. It has a half-life of 1.5 million years.

1. Draw a graph showing the decay of this isotope over the course of 7.5 million years. Include the time elapsed on the *x*-axis and the percentage of isotope remaining on the *y*-axis.
2. Indicate how many total half-lives have occurred at each half-life.
3. Calculate how many grams of the isotope would remain in a fossil that is 6 million years old if it originally contained 0.58 gram of the isotope.

The sedimentary rocks that contain fossils also preserve, encrypted in their physical features and chemical composition, information about the environment in which they formed. Sandstone beds, for example, may have rippled surfaces, like the ripples

produced by currents that we see today in the sand of a seashore or lake margin. This finding suggests the presence of water. Pyrite (FeS 2) (FeS_2), or fool's gold, forms when H 2 S H_2S generated by anaerobic bacteria reacts with iron. Because these conditions generally occur where oxygen is absent, the presence of pyrite in ancient sedimentary rocks can indicate that the environment was depleted of oxygen at the time that the rock formed.

In summary, fossils are a very powerful way to learn about our evolutionary past and provide strong evidence for evolutionary change

over time. Although the fossil record is incomplete, what we have provides direct evidence of organisms that lived in the past. In addition, radioactive decay of isotopes in rock formations where fossils are found allows us to date fossils and place them along Earth's long timeline. Fossils can be thought of snapshots of evolutionary history, giving us stunning pictures of past life.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be familiar with how scientists use the age of sedimentary rocks and radioactive decay to help determine the age of ancient organisms or fossils. You should be

able to explain these methods and use examples to describe the evolution and relatedness of species.

✓ Concept Check

6. **Describe** conditions in which fossilization is likely.

7. **Describe** the technique that is used to date fossils.

44.4 The distribution of organisms on Earth sheds light on evolutionary history

Traits of living organisms and fossils provide evidence of evolution and give us a window on what common ancestors likely looked like. A third

piece of evidence comes from what might at first seem like an unlikely source—the distribution of organisms on the face of Earth, what scientists call biogeography.

Species are typically adapted to their environment, but that doesn't mean that species live in all the places they possibly can. Penguins, for example, live in the southern hemisphere, but not the northern hemisphere, even though there are similar environments in both places. Similarly, kangaroos and other marsupial mammals live in Australia, but not Africa, in spite of similar habitats on both continents.

Why do species live in some places and not in others? Why do they only live in a subset of the places to which they are adapted? The answer is based on their evolutionary history: species originate in one place and then they disperse. But they can only spread out until they reach a barrier to migration. For penguins, the barrier is the warm weather toward the equator, effectively blocking them from making their way northward. For kangaroos, the barrier is the Indian Ocean because kangaroos can't swim.

In other words, we only need two pieces of information to figure out the distribution of all species on Earth:

where a species first originated, and how it is able to migrate or disperse from this point of origin. Therefore, the distribution of organisms gives us information about the evolutionary past.

Islands provide an interesting case study of biogeography. They are often far from the nearest mainland, and therefore may be difficult to get to. In addition, many of them, such as the Galápagos Islands and Hawaiian Islands, are volcanic in origin. As a result, when they formed, there were no organisms present. All the organisms on these islands had to migrate there in some way. They may have migrated on their own, by flying

or swimming, or they may have hitched a ride in some way, on a floating log or with the help of humans, for example. Regardless of how they got there, when they arrived, there were many open habitats available to them—habitats that were likely not open to them on the mainland. These open, new habitats provided selective pressures that resulted in the evolution of many new species, all descended from the original first species to arrive.

Species that evolved in this way are often found only in one place and not in others, and are therefore considered endemic. Islands have many examples of endemic species.

Darwin's finches on the Galápagos are an example: they are found there but nowhere else in the world. Other examples of endemic species include lemurs in Madagascar, Tasmanian devils on the island of Tasmania, and Komodo dragons on Komodo and a few surrounding islands, as shown in **FIGURE 44.12**.

FIGURE 44.12 Endemic species

Endemic species are found in one place and nowhere else. (a) Darwin's finches such as the large ground finch (*Geospiza magnirostris*) are found in the Galápagos Islands; (b) lemurs (*Lemur catta*) are found in Madagascar; (c) Tasmanian devils (*Sarcophilus harrisii*) are found in Tasmania; and (d) Komodo dragons

(*Varanus komodoensis*) on found on Komodo and nearby islands.

We can learn another lesson from biogeography. Because species don't typically live in all the places they could, if they are moved to a new, suitable habitat, they sometimes spread rapidly due to the absence of predators and other checks on population growth. Non-native species that become established in new ecosystems are termed **invasive species.** Freed from the natural constraints on their population growth, these species can expand dramatically when introduced into new areas, sometimes with negative consequences for native species and

ecosystems.

Species can sometimes be transported long distances by natural processes. For example, the Gulf Stream and North Atlantic Drift occasionally carry coconuts from the Caribbean to the coast of Ireland. Migratory birds can transport microorganisms across continents. Recently, however, humans have dramatically increased dispersal of organisms, resulting in many examples of invasive species. Ships fill their ballast tanks with seawater in Indonesia and empty it into Los Angeles Harbor, carrying organisms across the Pacific Ocean. Insects in fruit from South America wind up on

a dock in London. Humans have become major agents of dispersal, adding new complexity to twenty-first-century ecology.

Some of the invasive species that have become established in their new surroundings do little beyond increasing community diversity, but others put strong pressure on native species. Two highly disruptive invasive species are shown in **FIGURE 44.13**. The zebra mussel, shown in Figure 44.13a, provides an example. It is a European clam that hitchhiked to the Great Lakes in the ballast water of cargo ships. Like many invasive species, it has multiplied dramatically in its new habitat, displacing native

species and clogging intake pipes to power plants. Nearly 500 introduced species contribute disproportionately to crops lost each year to competition from weeds. And in Australia, more than 10% of all indigenous mammal species have become extinct in the past 200 years, largely because European colonists introduced cats and red foxes into their new home.

FIGURE 44.13 Invasive species

Invasive species are non-native species that become established in a new ecosystem and spread rapidly, often to the detriment of native species. They illustrate that species live in only a subset of the habitats that they could. (a) The zebra mussel (*Dreissena*

polymorpha), introduced into the Great Lakes from Europe in 1985, disrupts lake ecosystems, threatening native biological diversity. (b) The brown tree snake (*Boiga irregularis*), introduced into Guam from Asia and Australia shortly after World War II, has decimated indigenous bird populations across the island.

Invasive species have particularly devastating effects on islands because island species have commonly evolved with relatively few competitors or predators. Bones in Hawaiian lava caves record more than 40 bird species that existed 1000 years ago but are now extinct, eliminated by the rats and pigs introduced by

Polynesian colonists, as well as by habitat destruction. Introduced predators have had a similar impact on the island of Guam. Brown tree snakes, shown in Figure 44.13b, introduced from Australasia since World War II have reduced native bird and reptile diversity by 75%.

Such introductions contribute to the changing diversity and ecology of twenty-first-century landscapes, but it may be the spread of modern diseases that should concern us most. In a world filled with airplanes and oceangoing ships, bacteria and viruses spread much more rapidly than they did in our pre-industrial past. The SARS-CoV-2 virus, which

causes the disease COVID-19, is a recent and tragic example. The first diagnosed case was identified in December 2019 (hence the 19 in the name of the disease), and in just a few months became a global pandemic.

✓ Concept Check

8. **Describe** two factors that determine the distribution of organisms around the world.

9. **Describe** invasive species.

Module 44 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Using examples from the module, **describe** how molecular data can provide evidence of evolution.

LG 44.1 Homologous traits provide evidence for common ancestry.

- Traits that are shared by two or more species because of common ancestry are homologous. Page

616

- The amniotic egg evolved in the common ancestor of reptiles, birds, and mammals. Page 617
- Walking legs evolved in the common ancestor of tetrapods, including amphibians, reptiles, birds, and mammals. Page 617
- The nucleus, mitochondria, membrane-bound organelles, linear chromosomes, and genes containing exons and introns evolved in the common ancestor of eukaryotes. Page 617
- Homologous traits can be anatomical (morphological), cellular, or molecular. Page 618
- The nucleotide sequence of DNA and RNA, and the amino acid

sequence of proteins provide evidence common ancestry. Page 618

LG 44.2 Vestigial structures provide a window on the past.

- A vestigial structure is a structure that has lost its original function over evolutionary time and is now much reduced in size and/or function. Page 619
- Examples of vestigial structures include the whale hip bone, the human appendix, and wings in flightless birds. Page 619
- Genes can also lose function over time and become pseudogenes; because pseudogenes have no function, they mutate rapidly and

can be used as a measure of evolutionary relatedness between species. Page 619

LG 44.3 Fossils provide direct evidence of past life.

- Fossils are the remains of organisms preserved in sedimentary rocks. Page 620
- The fossil record is incomplete because fossilization requires burial in sediment, and fossils typically preserve only the hard parts of organisms, such as skeletons and shells. Page 620
- Fossils provide unique information, such as species that are now extinct, transitional forms between modern-day

species, and clues about environmental history. Page 622
- Rock layers can give relative dates of fossils, with older ones deeper than younger ones. Page 624
- Radioactive decay of unstable isotopes of elements provides a means of dating rocks. Page 624

LG 44.4 The distribution of organisms on Earth sheds light on evolutionary history.

- Biogeography is the study of the distribution of species on the Earth. Page 626
- Biogeography provides information about the evolutionary history of organisms, specifically where

they originated and how they were able to disperse. Page 627

- Islands provide unique habitat and have high numbers of endemic species, which are found in one place and nowhere else. Page 627
- Invasive species are non-native species that become established in new habitats, where they can disrupt ecosystems. Page 628

Review Questions

1. Traits that are similar in two species as a result of common ancestry are referred to as

A. homologous.
B. analogous.
C. convergent.
D. characteristics.

2. The layers of rock give information about relative dates; absolute dates weren't established until the discovery of

A. radioactive decay.
B. atoms.

C. sedimentary rocks.
D. fossils.

3. How do fossils provide evidence of evolutionary history?

A. Fossils provide an accurate account of the number of species that exist at any particular time.
B. DNA from older fossils allows us to construct complete molecular phylogenies.
C. Fossils provide a record of extinct species.
D. Fossils provide full information on extinct species.

4. What is the first event in the fossilization process?

A. Erosion of soils around the organism
B. Burial of the organism by sediments
C. Conversion of organic tissue to minerals (rock)
D. Hardening of sediments into rock.

5. Which is most likely to fossilize?

A. A crayfish that died in its muddy burrow by a creek
B. A jellyfish that died and sunk to the bottom of the ocean
C. A lizard that died on a mountainside
D. A leaf that fell from a tree and landed on the forest floor

6. The half-life of carbon-14 is 5730 years. If a sample contained 100% carbon-14 and 0% nitrogen-14 at a point in time 17,190 years ago, then what percentage of carbon-14 would it contain today?

A. 12.5%
B. 25%
C. 50%
D. 75%

7. The discovery of *Tiktaalik roseae* was significant for which of the following reasons?

A. It provided evidence that terrestrial (land-based) vertebrates are descended from fish.

B. It provided evidence that birds and dinosaurs are closely related.
C. It was the first fossil to be found with soft parts preserved.
D. It provided evidence that the continents once formed a supercontinent.

Module 44 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions

1–4.

1. Which is a potential consequence of fossils being more likely to form in some environments than others, and some organic materials being more likely to fossilize than others?

   A. The numbers and types of species that once lived on land could be underestimated.
   B. Fossils of marine organisms could be more reliable measurements of relatedness than molecular data could.
   C. Organisms without a skeleton or a hard shell could be overrepresented in the fossil record.

D. Fossils of extinct organisms could lead to incorrect interpretations of data from transitional forms.

2. Which is likely to evolve with the slowest molecular clock?

A. A pseudogene
B. A gene for a vestigial structure
C. An intron of a conserved eukaryotic gene
D. The exons of a conserved eukaryotic gene

Questions 3 and 4 refer to the following information.

Scientists examined a cliff composed of four layers of sedimentary rock. In

the surface layer, the scientists found the fossil stem and petals of a flowering plant. In the second layer, the next layer down from the surface, they found a fossilized dragonfly. In the third layer, the scientists found the fossilized bones of a fish. In the fourth and lowest layer, the scientists found a fossilized shell. Radiometric dating was used to determine that the fourth layer of sedimentary rock is 500 million years old and the second layer of sedimentary rock is 250 million years old.

1. Which places the fossils in the correct order, from oldest to youngest?

   A. Shell, fish, dragonfly, flower

B. Shell, dragonfly, fish, flower
C. Flower, fish, dragonfly, shell
D. Flower, dragonfly, fish, shell

2. Which provides the best estimate of the age of the fish?

A. Older than 500 million years
B. Between 500 and 250 million years old
C. 125–250 million years old
D. Younger than 125 million years old

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples.

Where calculations are required, show your work.

The rate at which radioactive isotopes decay can be used to determine the age of fossils. A scientist studying fossil remains of a wooly mammoth determined that the fossil tissue contained 5.5 mg of the isotope 14C ^{14}C. Based on the total mass of the fossil and the abundance of 14C^{14}C found in living organisms, the scientist estimated that the fossil material originally contained 44 mg of 14C^{14}C when the mammoth was alive. The half-life of 14C^{14}C is 5730 years.

a. **Calculate** the age of the fossil.
b. **Describe** whether 14C^{14}C can be

used to determine the age of fossils that are older than approximately 50,000 years.

c. Scientists use an isotope of uranium, 235U^{235}U, to test the age of ancient rock sediments. The half-life of 235U^{235}U is 704 million years. However, uranium is not found at high enough levels in plant and animal tissues to be directly measured in fossils. **Describe** how scientists can use the decay of 235U^{235}U to estimate the age of biological fossils.

Module 45
Continuing Evolution

LEARNING GOALS

- **LG 45.1 Evolution is an ongoing process.**
- **LG 45.2 Pathogens evolve resistance to antibiotics and cause new diseases.**
- **LG 45.3 Climate change leads to adaptation, migration, and extinction.**

In the last few modules, we have defined evolution, described the

mechanisms by which it occurs, and provided evidence for it. From these discussions, it might seem that evolution is something that occurred in the past. Indeed, the traits of living organisms, the features of fossils, and the distribution of organisms on Earth help us reconstruct the past. From these pieces of data, we can understand the evolutionary history of organisms and understand the paths they took to their current forms.

Just as evolution has shaped life on Earth from its inception, it remains an ongoing process and continues to shape life on this planet. All the mechanisms of evolution—natural

selection, genetic drift, mutation, migration, and nonrandom mating—continue to operate in modern-day populations. Furthermore, as environments change because of human activities—building cities and roads; transforming forests and grasslands to farms and fields; using antibiotics, pesticides, and herbicides; and burning fossil fuels—the selective pressures on organisms are changing as well. In essence, humans are agents of evolution. While humans have played a role in shaping the environment for tens of thousands of years, the human footprint has become bigger and the pace of change has increased rapidly over the last century. We can measure

and record these changes in populations in real time.

In this module, we will discuss evolution as an ongoing, continuing, and contemporary force, shaping organisms and populations today as it has done in the past. Although evolution happens in all populations over time, we see it most dramatically when the environment is altered. Therefore, in this module we will primarily focus on examples in which organisms respond to a change in the environment, such as the movement from land to water during the evolution of whales, a recent drought on the Galápagos Islands, the widespread use of antibiotics, and

climate change.

FOCUS ON THE BIG IDEAS

45.1 Evolution is an ongoing process

As we discussed in earlier modules,

many species are remarkably adapted to their environment. This close fit is the result of natural selection, in which organisms that survive and reproduce best in a particular environment leave more offspring, and these offspring inherit the variations that allowed their parents to do so well in that environment. In a stable environment, we see the results of past selective pressure and the adaptations of organisms well suited to the environment. As an environment changes, populations will change under the influence of natural selection. This is an example of directional selection, as we discussed in Module 41.

Life continues to evolve in a changing environment, now as it has done in the past. In this section, we will look at fossil and genomic evidence of recent evolutionary change, and then look at two examples of evolution that are happening today.

Continuous Change in the Fossil Record

As we discussed in Module 44, fossils provide some of the best evidence for evolutionary change. Fossils provide a direct link to the past. One of the most dramatic and best documented cases of evolutionary change in the fossil record is the evolution of whales from land-based mammals.

Today, there are two groups of whales, both shown in **FIGURE 45.1**—baleen whales such as humpback whales (*Megaptera novaeangliae*), and toothed whales such as killer whales (*Orcinus orca*). Both of these groups of whales are mammals. They have the defining characteristics of all mammals, including mammary glands, hair, a four-chambered heart, three middle ear bones, and warm bloodedness, among others.

FIGURE 45.1. Two groups of whales

There are two major groups of whales—baleen and toothed whales. (a) The humpback whale is a baleen whale and a member of the Mysticetes group of whales. (b) The killer whale is a toothed

whale and a member of the Odontocetes group of whales.

Whales have descended from land-based mammals over the last 50–60 million years, which is relatively recently in evolutionary history. During this time, their features changed dramatically as they adapted to life in the water. For example, the hindlimbs became shorter and shorter over time, until they were lost completely in modern whales. The forelimbs were modified from legs to fins. The tail evolved to become shorter and more powerful, as it is used to propel whales and their recent ancestors through the water.

The eyes shifted to the side of the head and the nasal opening moved to the top of the head, both of which are adaptations for living in the water.

These anatomical changes are all documented in the fossil record, as we can see in **FIGURE 45.2**. In this figure, we see a timeline across the bottom, and reconstructions of some of the major fossils showing the changes that occurred as whales moved from land to water. These adaptations evolved by natural selection: in the water, individuals with smaller hindlimbs, a tail, and other changes in body form would have survived better and left more offspring than other individuals,

leading to a change in the population over time.

FIGURE 45.2 Whale evolution

The fossil record has revealed continuous change in the anatomy of whales as they transitioned from land to water.

Adapted from: Zimmer, C. 2001. *Evolution: The Triumph of an Idea.* New York: Harper Collins.

Whales are mammals but look like sharks and other fish. This is a dramatic example of convergent evolution, in which similar traits evolve independently in two groups because of similar selective

pressures. It demonstrates how the selective pressure of living in the water can shape distantly related organisms to look very similar to one another. Recall from Module 44 that similarities that result from convergent evolution are analogous, like the tail of fishes and the tail of whales.

The evolution of whales is not the only example of well-documented, continuous change in the fossil record. We have may other examples, including the evolution of amphibians from fish about 380 million years ago, birds from their dinosaur relatives about 150 million years ago, horses over the last 60 million years, and

humans and their extinct relatives over the last 6 million years. The fossil record also reveals species that have not changed very much over time, such as sharks and horseshoe crabs, which are sometimes called living fossils. In these cases, any changes in their outward forms are selected against, providing an example of stabilizing selection.

Genomic Changes over Time

The changes that we see in the fossil record over time as the ancestors of modern whales moved from the land to the water are anatomical. Physiological changes occurred

alongside anatomical ones as whales adapted to life in the water. For example, whales are able to hold their breath for long periods and have to deal with the high pressure of the deep sea and the high salt environment of the oceans. Note that the environment doesn't cause changes in anatomy or physiology. Instead, variation in anatomical and physiological traits are present in the population, and the environment acts as a selective force, favoring those variations that increase survival and reproduction in that environment. Anatomical and physiological changes in turn require changes in genes that control development, physiology, and anatomy.

In some cases, we can find ancient DNA that provides evidence of genomic change over time. The oldest DNA that has been found and sequenced comes from the tooth of a mammoth that lived approximately 1 million years ago. While we can learn a lot from ancient DNA, we do not have DNA that stretches back 60 million years to record the evolution of whales from their land-based ancestors. To understand changes that occurred in the genomes of whales over the last 60 million years, we can instead take a comparative approach. In other words, we can look at genomes of modern whales and compare them with the genomes of other mammals to see if we find

changes in key genes that allowed whales to adapt to a watery environment.

One study looked at myoglobin, which is the protein in your muscle that binds oxygen and gives muscle (and meat) its red color. The more myoglobin there is in muscle, the redder it is. In whales, the muscle is almost black as a result of the high concentration of myoglobin. More myoglobin means more oxygen in muscle tissue. The high concentration of myoglobin in muscle is one adaptation that allows whales to store oxygen for so long.

Proteins tend to aggregate at high

concentration, which can interfere with their function. Whale myoglobin, however, has been modified over time. Compared with myoglobin from other mammals, whale myoglobin has a higher negative charge on its surface, allowing the proteins to repel one another and not clump together, even though they are so densely packed. The high negative charge on the surface of the protein in turn is a result of changes in the myoglobin gene. Small changes in the myoglobin gene led to changes in mRNA and protein, leading to an altered protein that can be present in high concentrations without aggregating, thereby allowing whales to store

more oxygen in their tissues.

Myoglobin is encoded by a single gene. Can we see examples of larger changes in genomes over time? The genomes of thousands of species have been sequenced, allowing researchers to look at sequence differences, gene order along a chromosome, and number of chromosomes in different species. The whale genome has been compared to other mammalian genomes. One of the major differences is the inactivation of 85 genes in whales as they transitioned to life in the water. To understand why and how these genes were silenced over time, scientists are

studying how they are turned off and their function.

In addition to comparing whale genomes to genomes of land-based mammals, we can compare other genomes. The human genome and chimpanzee genome are remarkably similar because the two species are very closely related. The human genome and the mouse genome are much more different because there has been more time since they shared a common ancestor. The genomes of humans and mice are roughly the same size with the same number of genes. However, humans have 23 chromosomes, while mice have 20 chromosomes; the centromere is

centrally located in most human chromosomes, but it is located toward the end in mice chromosomes; and there are some areas in which the order of genes has been shuffled in humans compared to mice. Scientists continue to study how these genomic changes lead to changes in the anatomy, physiology, behavior, and other traits of humans and mice.

AP® EXAM TIP

PREP FOR THE AP® EXAM

The simple change of a molecule, such as the negative charges of myoglobin, can become an adaptation selected through natural selection. This is an example of a biological adaptation of basic

biochemistry in response to a selective pressure.

Evolution in Our Time

The evolution of whales from their land-based ancestors is recent, but still occurred in the evolutionary past. Can we see any examples of evolution in animals happening today?

For many years, Peter and Rosemary Grant have studied in exquisite detail the populations of Darwin's finches on a tiny island in the Galápagos, Daphne Major. Because the island is so small, they have been able both to track every bird in the population and

to monitor the resources, such as seeds for food, available to the birds. The island typically has a dry climate, with just 130 mm of rain falling during the wet season. Occasional years are much drier, with just 24 mm of rainfall, and in 1977 there was a severe drought. This had a dramatic impact on the island's vegetation, markedly reducing the amount of food available to the birds.

As a result, the population of the medium ground finch (*Geospiza fortis*) crashed during this time. Curiously, the size of seeds available as food shifted significantly over the course of the drought because plants that produce large seeds survived better

than ones producing small seeds. Birds with small beaks had trouble breaking open these large, hard seeds, meaning that birds with bigger beaks were at an advantage.

Beak size is a trait that the Grants, following Darwin, have studied intensively. They had already established that it is highly heritable, meaning that most of the variation seen in beak size from bird to bird is attributable to genetic differences (rather than differences in nutrition, for example). They did this by comparing the beak size of offspring to the beak sizes of their parents and finding a strong positive correlation between the two. Put simply, two

large-beaked parents tended to produce large-beaked offspring, and two small-beaked parents tended to produce small-beaked offspring.

Because of the differential survival of small- versus large-beaked birds in the drought, the average beak size of the survivors was larger than that of the pre-drought population. In the next generation, the offspring of the drought survivors had larger beaks than the pre-drought birds. **FIGURE 45.3** shows what happened in graph form. Beak size is plotted on the *x*-axis and number of finches on the *y*-axis. The distribution of beak sizes in 1976 is shown in Figure 45.3a, and the distribution of beak sizes in 1978 is

shown in Figure 45.3b. We can see a clear difference in the distribution of beak size before and after the drought. In 1978, after the drought, the distribution has shifted to the right. The peak of the beak distribution in each graph reflects the most common beak size. The most common beak size in 1976 is 8.8 cm, whereas the most common beak size in 1978 is 9.8 cm, which is a full centimeter larger in just 2 years. The increase in beak size over this 2-year period is an example of directional selection, as discussed in Module 41.

FIGURE 45.3 Evolution of larger beaks in response to a drought

Directional selection in a population of

Galápagos finches caused a shift toward larger beaks as a result of a drought in 1977. The average beak size in 1976 distribution (a) is about 8.8 cm, and the average beak size in the 1978 distribution (b) is about 9.9 cm. The drought led to the evolution of larger beaks from 1976 to 1978.

Data from Freeman & Herron *Evolutionary Analysis* 2004.

What is remarkable about this observation is that the impact of a single bout of severe weather has had, in effect, an instantaneous evolutionary effect on the population. We typically think of natural selection as a long, slow process, but,

sometimes, it can happen extremely quickly.

A second interesting example comes from Nebraska, where another husband-and-wife team, Charles and Mary Brown, studied cliff swallows, shown in **FIGURE 45.4**. These birds usually nest on rock ledges and cliffs, as their name suggests, but more recently have started to build nests under bridges as highways have expanded across their range. This location puts them at risk of being hit by passing cars as they travel under the bridge. In effect, bridges are providing a new environment for the cliff swallows, and cars a new selective pressure.

FIGURE 45.4 Cliff swallows

Cliff swallows are social birds that form large colonies. They typically build their nests underneath rock ledges in mountains and canyons, and more recently on buildings and under bridges, as shown here.

The researchers studied road kill—birds that were hit by cars. They noticed that the number of birds hit by cars declined over time, suggesting that the birds were better able to avoid getting hit by cars over time. They also noticed that the wing length of birds that were killed was longer than that of the general population, suggesting that birds with longer wings tended to get hit by cars

more than birds with shorter wings. Putting the two observations together, they reasoned that the birds evolved shorter wings over time as an adaptation to living under bridges. The shorter wings made them better able to maneuver and avoid being hit by oncoming cars.

These two examples demonstrate that, by doing careful measurements, it is possible to see the effects of evolution over just a few generations. And they both provide examples of evolution occurring in our time.

✓ Concept Check

1. **Describe** three anatomical changes that occurred as the ancestors of

modern whales moved from the land to the water.

2. **Explain** what the Grants learned about evolution from the 1977 drought in the Galápagos.

45.2 Pathogens evolve resistance to antibiotics and cause new

diseases

One of the most dramatic examples of continuing evolution comes from bacteria and other pathogens that cause human diseases. These are evolving in two ways, which we will discuss in this section. First, the widespread use of antibiotics is leading to the evolution of antibiotic resistance. Second, new pathogens are emerging that we have not been previously exposed to. Both of these are dramatic demonstrations of evolution in action, and they are also fast becoming a public health crisis.

Antibiotic Resistance

From the Black Death of the

fourteenth century to the flu outbreak of 1918, infectious diseases have played a major role in human history. Today, we have unprecedented opportunities to control or even eradicate some of these infectious diseases through improved public health measures, vaccines, and antibiotics. At the same time, the use of antibiotics and similar drugs inevitably leads to the evolution of antibiotic resistance.

The strong selective pressures placed on pathogens by antibiotics pose a key challenge for twenty-first-century medicine. Tuberculosis provides an example. Tuberculosis is very common, affecting an estimated one-

third of the world's population and causing 1.8 million deaths annually, mostly in sub-Saharan Africa. Symptoms are absent in most cases. Approximately 10% of cases, however, are active. Active cases are characterized by chronic cough, fever, night sweats, and weight loss.

Tuberculosis is caused by the bacterium *Mycobacterium tuberculosis*. Antibiotic treatment is effective against tuberculosis, but antibiotic resistance is on the rise. In 2018, approximately half a million new cases of antibiotic-resistant tuberculosis were reported worldwide. A small percentage of these infections has been

characterized as “extremely drug resistant,” meaning that the pathogens resist both standard treatments and alternative antibiotics developed over the past 25 years. **FIGURE 45.5** shows the distribution of extremely drug-resistant tuberculosis around the world. In effect, extremely drug-resistant tuberculosis is untreatable.

FIGURE 45.5 Distribution of extremely drug-resistant tuberculosis around the world

Recently, 8000 patients with extremely drug-resistant tuberculosis were reported.

Data from https://apps.who.int/iris/bitstream/

handle/10665/329368/9789241565714-eng.pdf?ua=1

The evolution of antibiotic resistance is an example of natural selection in action, as we discussed in Modules 40 and 41. There is genetic variation among the bacteria that cause tuberculosis in terms of their sensitivity to antibiotics: the majority of bacteria are sensitive, but some are resistant. When we use antibiotics, we select for those that are antibiotic resistant. That is, the antibiotic-resistant bacteria survive and reproduce more than the antibiotic-sensitive ones. As a result, the population changes from being

mostly antibiotic sensitive to mostly antibiotic resistant.

Malaria provides another example of natural selection. Malaria is a disease that causes fevers, chills, headaches, muscle pain, and sometimes even death. It is caused by a single-celled eukaryote, or protist, of the genus *Plasmodium*. There are five species of *Plasmodium* that infect humans. One of them, *P. falciparum,* is particularly dangerous, accounting for the vast majority of malaria fatalities. The malaria parasite is transmitted to humans by the bite of a female *Anopheles* mosquito, shown in **FIGURE 45.6**. In any given year, malaria infects an estimated 500

million people, causing 1 million or more deaths. Infection is particularly severe in parts of Africa, where the direct and indirect effects of malaria account for almost half of all childhood mortality.

FIGURE 45.6 Malaria

The malaria parasite, a single-celled eukaryote, is transmitted by the bite of a female *Anopheles* mosquito, shown here.

For centuries, humans have fought the infection with quinine, a chemical found in the bark of the South American *Cinchona* tree. In the 1940s, scientists developed a more sophisticated drug based on quinine, called chloroquine. Chloroquine was

effective, inexpensive, and easy to administer. As a result, it was widely used. Unfortunately, in the late 1950s, the malaria parasite began showing signs of resistance to chloroquine. Within 20 years, the resistance had spread to Africa, so that today the once-potent medication is no longer effective against most strains of the parasite.

Since that time, many new antimalarial drugs have been developed. Over time, their usefulness has declined as resistance to each of these drugs has evolved in populations of *Plasmodium*. For example, in 2015, Chinese scientist Tu Youyou won the Nobel Prize in

Medicine or Physiology for her work in identifying artemisinin, the active antimalarial component in sweet wormwood (*Artemisia annua*). This a plant, shown in **FIGURE 45.7**, has long been used in Chinese traditional medicine. Today, artemisinin and its derivatives are key to our attempts to combat malaria, but even here, within a few years of their first being deployed against malaria, resistance has emerged.

FIGURE 45.7 Sweet wormwood

Sweet wormwood (*Artemisia annua*) is the source of artemisinin, which has recently been used to treat infection by the malaria parasite.

A similar process plays out when we

treat insects with insecticides, pests with pesticides, and plants with herbicides. In each case, we are selecting for resistance among these groups of organisms over time. In the case of malaria, which is transmitted by mosquitoes, insecticide-soaked bed nets have proved a highly effective means of protection against malaria in affected areas, reducing transmission by as much as 90%. Natural selection, however, has begun to chip away at success in controlling the disease: mosquito strains have begun to emerge that are resistant to some insecticides.

Not only are humans affecting the malaria parasite; the malaria parasite

has also affected humans. The battle between malaria and humankind has raged through the ages. Scientists have recovered DNA of the malaria parasite from the bodies of 3500-year-old Egyptian mummies—evidence that ancient humans were infected with the malaria parasite. The close connection between humans, mosquitoes, and the malaria parasite almost certainly extends back much further.

In fact, people who come from regions where malaria is endemic are more likely than others to have certain genetic changes compared with people who come from malaria-free regions. For example, as we

discussed in Module 37, the *S* allele as a heterozygote provides some protection from infection by malaria. This observation indicates that the malaria parasite has been exerting evolutionary pressure on humankind for quite some time.

This back-and-forth between antibiotics and pathogens—where we take steps or evolve changes to prevent infection, and the parasite in turn evolves traits to circumvent these defenses—is not limited to tuberculosis and malaria, but instead characterizes nearly the whole range of diseases caused by viruses, bacteria, protists, and fungi that infect humans. Clearly, despite the

remarkable gains of the twentieth century, public health will remain a key issue in the decades ahead. Improved sanitation, in the form of clean drinking water and safe food, can do much to reduce transmission of infectious diseases. In addition, the search continues for vaccines that can further reduce or even eliminate some historic scourges. Even so, the ongoing evolution of drug resistance requires the continuing efforts of scientists to stay one step ahead of pathogens.

AP® EXAM TIP

PREP FOR THE AP® EXAM

Remember that evidence of evolution

can come from the present as well as from the past. In the present, we see examples such as antibiotic resistance in bacteria, the size of finch beaks, and variation in gene sequences. From the past, we can compare the traits of fossil organisms with those of living organisms, and compare ancient and modern DNA.

Emerging Diseases

In addition to resistance, new strains of viruses, bacteria, and other pathogens continue to evolve. As we saw in Module 39, an emerging disease is an infectious disease that has appeared recently or spreads rapidly. A recent example is SARS-CoV-2, the virus that causes the

disease COVID-19 and caused a worldwide pandemic in 2020 and 2021, which is discussed in Module 39. Other examples include the human immunodeficiency virus (HIV), Zika virus, certain strains of the flu virus, and Ebola. Emerging diseases like these and others evolve in such a way that they are able to spread more easily, cause more severe disease, or even infect new species of organisms.

For example, pathogens that typically cause mild disease may evolve to become more virulent. This has occurred multiple times in the flu (influenza) virus. Influenza is an RNA virus that infects mammals and birds.

It is notable for causing seasonal outbreaks. However, four times in the last century, most notably in 1918, the virus spread more widely than usual, infected more people, and caused more severe disease. These changes result at least in part from mutations that occur in the virus and then spread through the population of viruses. Some of these mutations lead to new traits, such as the ability to spread more quickly from person to person, infect a host cell more easily, or influence the immune response of the host.

Pathogens may also change their host specificity over time. That is, pathogens that infect one group of

organisms may change in such a way that they are able to infect a new group of organisms. Host specificity results from the way that viruses enter cells, as discussed in Module 39. Proteins on the surface of the virus bind to proteins on the surface of host cells. These proteins interact in a specific manner, and it is this interaction that determines the types of cells and organisms that a virus can infect.

The host range of a virus can change as viral surface proteins evolve over time to interact with new host cell proteins. For example, avian, or bird, flu is a type of influenza virus that was once restricted primarily to birds

but now can infect humans. The first reported case in humans was in 1996, and the disease has since spread widely. Similarly, HIV once infected only nonhuman primates such as chimpanzees, but its host range expanded in the twentieth century to include humans. The SARS-CoV-2 virus is thought to come from bats, but recently evolved in such a way that it now infects humans. Today, we see SARS-CoV-2 evolve with the emergence of new variants. Scientists are studying how these variants differ from one another in terms of ease of spread and severity of disease.

These examples illustrate how ongoing evolution in viruses can lead

to changes in their host range, causing new, emerging diseases.

45.3 Climate change leads to

adaptation, migration, and extinction

One of the most dramatic ways the environment is changing today is the warming of the planet, leading to global changes in the climate and oceans. Species are responding to the changing climate in different ways. We tend to think about natural selection in terms of populations adapting to a constant or slowly changing environment. In the twenty-first century, however, the environment will probably be a rapidly moving target, so genotypes that conferred high fitness in the past may not prove advantageous in the future. In this section, we will briefly

introduce the topic of climate change and then discuss three ways that populations are responding: some are adapting; some are migrating; and some are going extinct.

Climate Change

Every year, humans are adding significant amounts of carbon dioxide (CO2)(CO_2) to the atmosphere. We do this primarily by burning fossil fuels and setting fire to rainforests, as shown in **FIGURE 45.8**. Clearing forests for agriculture generates still more CO2CO_2. When preparing land for agriculture, the existing vegetation is generally burned off, converting much of the

carbon in biomass and soil to CO2CO_2

.

FIGURE 45.8 Human-generated sources of carbon dioxide

Every year, humans add carbon dioxide to the atmosphere, predominantly by (a) burning fossil fuels and (b) burning rainforests, as seen in the Amazon.

CO2CO_2 is a greenhouse gas, which is a gas in Earth's atmosphere that helps to warm the planet and is discussed more fully in Module 57. It acts like the glass panes of a greenhouse, which allow sunlight to enter but prevent heat from leaving. CO2CO_2 is just one of several greenhouse gases in the atmosphere: water vapor is another, and methane a third.

Without these gases absorbing and trapping heat, average surface temperatures would fall below freezing and life would not be possible. However, because CO2CO_2 levels are increasing rapidly, its greenhouse effect is also increasing. Likewise, methane levels are rising rapidly, in large part because of increasing food production. The thawing of permafrost at high latitudes releases additional methane that was trapped in frozen soils when the ice formed long ago.

As CO2CO_2 levels in the atmosphere are increasing, the surface temperature of Earth is also rising. For the past century, scientists,

sailors, and citizen scientists have monitored temperature at weather stations around the world. More recently, satellites have enabled us to measure temperature in places as remote as the high Arctic and the middle of the ocean. The results are clear: in most parts of the world, the surface temperature of Earth is increasing.

Effects of Changing Climate

What will be the consequences of climate change? Some areas will benefit. For example, temperature increase in New England and Scandinavia will mean longer

growing seasons. Other regions will suffer. As precipitation patterns change, many places will become drier, including already water-limited areas of the southwestern United States. A number of climate models predict that some of the strongest declines in rainfall will occur in regions that currently produce much of the corn and wheat that feed the world. Already, farmers in southeastern Australia have experienced the worst droughts in a century, and with them unprecedented damage from brushfires. Climate models also predict an increased frequency of strong hurricanes along the western margin of the Atlantic Ocean.

Scientists will be watching carefully to see whether such extreme events increase in frequency in the coming years.

Plants illustrate the complicated ways in which organisms respond to the new selective pressure brought on by environmental change. Meticulous notes taken during the 1840s by Henry David Thoreau provide an inventory of plant species in woodlands in Concord, Massachusetts. The graph in **FIGURE 45.9a** shows that mean annual temperature in this area has increased by about 2.5°C over the last 150 years. The graph in Figure 45.9b shows that many species of plants

flower a week earlier than they did in the nineteenth century. Earlier onsets of leaves, flowers, and fruit have also been documented throughout the temperate zones of North America, Europe, and Asia.

FIGURE 45.9 Plant response to warming temperatures

Observations over the last 150 years show the effects of warming temperatures in Concord, Massachusetts. (a) Regional temperatures have become warmer in the woods of Concord, Massachusetts. (b) As temperatures have become warmer, the time of first flowering has become earlier. Error bars are calculated as ±1 standard deviation on either side

of the mean.

Data from Miller-Rushing, A. J., and R. B. Primack. 2008. “Global Warming and Flowering Times in Thoreau’s Concord: A Community Perspective.” *Ecology* 89(2):332–341. doi: 10.1890/07-0068.1

Another response that plants show to elevated levels of CO2CO_2 is increased growth. Where nitrogen in the soil is abundant, increased CO2CO_2 levels tend to stimulate growth. However, in most terrestrial environments, soil nitrogen levels are low, limiting any growth response to elevated CO2CO_2. Moreover, increased drought stress and more frequent outbreaks of insect pests and wildfires may

counteract any capacity for accelerated growth.

Plants grown in air with CO2CO_2 levels like those predicted for the end of this century show other changes as well: the amount of nitrogen in plant tissues commonly declines, as does the proportion of resources devoted to reproduction. This difference doesn't reflect genetic change, but rather an individual plant's physiological response to altered environmental conditions. But if environmental change persists for a long time, the varying abilities of different plants to respond physiologically will result in changing allele frequencies, as some variants

survive and reproduce better than others. That is, plant populations may evolve by natural selection in response to climate change so they are better adapted to a warmer world.

Adaptation is one response to climate change, but, given the pace at which atmospheric composition and climate are changing, many populations may not have time to adapt, a process that typically takes place slowly over many generations. Another possible response to climate change is migration. Fossils deposited as Earth's climate warmed at the end of the last ice age show that many plant species dramatically changed their geographic distributions in response

to changing climate. Trees don't move, but they can migrate by dispersing seeds to new areas.

Migration is a potentially important response to environmental changes projected for the twenty-first century, but it requires a continuous route to get from one place to another, and it can be a challenge to find these direct paths on continents broken up by agricultural lands and cities. For this reason, some biologists advocate "assisted migration": the deliberate transplantation of plant populations from existing habitats to new ones more favorable to growth. To make sure that assisted migration does more good than harm, we need to do

further research to understand how plants grow and compete in new ecological situations and under different environmental conditions.

In addition to adaptation and migration, species may also go extinct if the environmental change is so extreme that there are no variants in the population capable of surviving and reproducing. A number of species have declined in abundance or even disappeared since Thoreau's time, and these tend to be the plants least able to change their flowering time. If they are unable to adapt to warmer temperatures, they may flower when there are no pollinators around, for example. This

observation highlights the fact that different plant species respond in distinct ways to changing climate, which favors some populations over others.

FIGURE 45.10 shows an estimate of the sensitivity of plants around the world to projected twenty-first-century climate. Areas in red are especially vulnerable: plants at high latitudes are particularly sensitive to warming, whereas tropical rain forests are more vulnerable to predicted decreases in cloud cover. In other areas, plants are most sensitive to predicted changes in water availability. Species in these regions could face diminished population

size, decreased growth rates, or even extinction.

FIGURE 45.10 Estimated sensitivity of global vegetation to twenty-first-century climate change

Red and orange indicate high vulnerability of vegetation, and green and yellow indicate low vulnerability of vegetation.

Data from Seddon, A. W. R., M. Macias-Fauria, P. R. Long, D. Benz, and K. J. Wilis. 2016. "Sensitivity of Global Terrestrial Ecosystems to Climate Variability." *Nature* 531:229–232.

✓ Concept Check

5. **Describe** how a greenhouse gas warms the planet.

6. **Identify** three greenhouse gases.

7. **Describe** three ways that species may respond to global changes in climate.

Module 45 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Use one example from the module to **describe** the connection

between environmental change and the evolution of a population.

LG 45.1 Evolution is an ongoing process.

- Continuous evolution is recorded in the fossil record of whales over the last 50–60 million years. Page 632
- Whales evolved from land-based mammals and adapted to life in the water. Page 633
- Continuous evolution is also apparent by comparing genomes of different species. Page 634
- Evolution is occurring today and is visible in Darwin's finches and cliff swallows. Page 635

LG 45.2 Pathogens evolve resistance to antibiotics and cause new diseases.

- The use of antibiotics is one of the success stories of twentieth-century medicine, but has led to antibiotic resistance, a major challenge for twenty-first-century biologists and physicians. Page 636
- Insecticide, pesticide, and herbicide resistance is also common as organisms evolve by natural selection. Page 637
- Evolution has led to new, rapidly spreading diseases, called emerging diseases. Page 638
- Emerging diseases may cause more severe symptoms, spread

more easily, or infect new species. Page 639

LG 45.3 Climate change leads to adaptation, migration, and extinction.

- Humans are adding significant amounts of carbon dioxide to the atmosphere, primarily through the burning of fossil fuels and the clearing of rainforests. Page 639
- Carbon dioxide is a greenhouse gas, trapping heat and thereby keeping the surface of Earth warm. Page 639
- Other greenhouse gases include methane and water vapor. Page 639
- Greenhouse gases play an

important role in maintaining temperatures on Earth that are compatible with life, but increasing levels of greenhouse gases are resulting in higher surface temperatures. Page 639

- Climate change has already affected the distribution of species and the composition of communities, and will likely continue throughout the twenty-first century. Page 641

Review Questions

1. All of the following changes occurred in the evolution of whales from land-based mammals except

A. loss of hindlimbs.
B. evolution of fins from

forelimbs.

C. development of gills.

D. evolution of a streamlined shape with a powerful tail.

2. The human genome is most similar to the

A. mouse genome.

B. chimpanzee genome.

C. whale genome.

D. HIV genome.

3. Emerging diseases

A. spread slowly.

B. are ancient diseases.

C. do not cause illness or death.

D. have only recently infected humans.

4. In addition to carbon dioxide and methane, which is also considered to be a greenhouse gas?

A. Oxygen
B. Carbon monoxide
C. Ozone
D. Water vapor

5. In response to global climate change, it is likely that some plant species will survive while others will go extinct. Which does not explain this pattern?

A. Greenhouse gases are toxic at current levels, so increasing levels of these gases will cause some plants to go extinct.
B. Plants differ in their abilities

to respond physiologically to persistent environmental change, and some will survive increased temperatures.

C. Temperatures may increase more rapidly than some species can adapt, which will lead to their extinction.

D. Some plants are able to migrate more effectively than others and can move into areas with more favorable conditions for survival.

6. Using records made by Henry David Thoreau in the 1840s, scientists have documented what pattern of change in flowering plants in Concord, Massachusetts?

A. As temperatures have warmed, flowering occurs earlier in many species.
B. As temperatures have warmed, flowering occurs later in many species.
C. As temperatures have become more variable, flowering occurs earlier in many species.
D. As temperatures have become more variable, flowering occurs later in many species.

Module 45 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice

Questions

Choose the best answer for questions 1–4.

1. Some organisms, such as crocodiles and horseshoe crabs, have shown very little evolution in their morphology, or the shape and structure of their bodies, over hundreds of millions of years. These organisms are sometimes called living fossils. Which explains why these “living fossils” remain morphologically unchanged?

   A. Mutations that change body structure do not occur in these species.

B. There is no natural selective pressure for these species to evolve a different morphology.
C. These species are incapable of evolution.
D. Morphological evolution in these species is not heritable.

Use the following information to answer questions 2 and 3.

The cerulean-capped manakin (*Lepidothrix coeruleocapilla*) is a tropical bird that lives in forests in the Andes mountains in South America. Global climate change has resulted in increased average temperature in the Andes, and, as a consequence, change in the ranges of the plants and animals that live there. The

abundance of *L. coeruleocapilla* was measured at different elevations on a mountain in Peru in 1985, and then again on the same mountain in 2017. The number of *L. coeruleocapilla* observed at each elevation in each year is given in the following table.

Sampling elevation (m)	**450**	**650**	**850**	**1050**	**1350**
Number of birds observed in 1985	**0**	**0**	**1**	**24**	**22**
Number of birds observed in 2017	**0**	**0**	**0**	**10**	**29**

Use the following figure to answer question 2.

1. Which plot best illustrates the data?

   A. a
   B. b
   C. c
   D. d

2. Based on the data provided, which is the best prediction of what would happen to the *L. coeruleocapilla* population on this mountain if climate change were to continue on its present trajectory?

   A. The birds would adapt to the higher temperatures.

B. The birds would be forced to migrate to a new mountain.
C. The birds would expand their range into lower elevations.
D. The birds would be at risk of extinction from the mountain if the highest elevations became too warm.

3. Pyrethroids are a class of chemical insecticides that are used to kill pest insects on farms. One use of pyrethroids is to control the number of house flies on dairy farms. However, after many years of use, pyrethroids have become less effective at reducing the number of house flies on farms. Which of the following statements is most

likely to explain this observation?

A. The house flies needed to resist the pyrethroid so they developed a mutation that prevents them from being killed.
B. House flies carrying a mutation that protects them from being killed by pyrethroids are able to survive and reproduce more than house flies that don't carry this mutation.
C. Each house fly evolved resistance to pyrethroids over their life span.
D. After many years of exposure, the house flies have learned to avoid environments

contaminated with pyrethroids.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

An industrial factory built on the shore of a river pumps in water from the river to maintain a low temperature, and then pumps the water back out into the river. The factory was built in 1950. In 1970, environmental scientists collected aquatic snails from a site just

downstream of the spot where the factory released water back into the river. The environmental scientists collected snails from the same spot again in 1994. In both years, the scientists also collected samples of the same species of snail from a site in the river upstream of the factory. Additionally, the scientists were able to secure museum samples of the snail that were collected from both locations in 1921, before the factory was built.

The *Tol1* gene encodes a protein that is involved in stress responses. There are two known alleles of the *Tol1* gene: *T* and *t*. The scientists determined the genotype at the *Tol1*

gene of all snail specimens and obtained the data shown in the table.

Location	Year	Genotype (percent)
		tt
Upstream of factory	1901	[illegible]
Upstream of factory	1970	[illegible]
Upstream of factory	1984	[illegible]
Downstream of factory	1901	[illegible]
Downstream of factory	1970	[illegible]
Downstream of factory	1984	[illegible]

a. **Construct** a histogram to illustrate the frequencies of all three genotypes in all three years at both locations.
b. **Describe** the role of sampling the site upstream of the factory in the experiment.
c. **Make a claim** to explain the difference in genotype

frequencies between the two locations in 1994.

d. **Propose a new experiment** to test the hypothesis that is described in part c above. **Describe** the results that would be expected from this experiment if the hypothesis is true.

Module 46

Phylogeny

LEARNING GOALS

- **LG 46.1 The history of life on Earth can be described as a branching tree.**
- **LG 46.2 Shared traits are present in more than one species.**
- **LG 46.3 Evolutionary trees can be built in several ways.**
- **LG 46.4 Phylogenetic trees can help solve practical problems.**

Life originated on Earth more than 3.5 billion years ago. Today, an

estimated 10 million species inhabit the planet. Short of inventing a time machine, how can we reconstruct those 3.5 billion years of evolutionary history in order to understand the extraordinary series of events that have ultimately resulted in the biological diversity we see around us today?

One way to explore evolutionary history is to look at fossils, which we discussed in Module 44. Fossils provide direct evidence of past life. The fossil record provides insights that we would otherwise not know or be aware of, such as information about extinct organisms and mass extinctions. At the same time, the

fossil record is incomplete because some organisms are more likely to be preserved than others.

Another way to understand evolutionary history is to look at traits of living organisms. As noted in Module 40, humans and chimpanzees are more similar to each other than they are to other primates. Humans, chimpanzees, and other primates in turn are more similar to one another than any one of them is to a mouse. And humans, chimpanzees, other primates, and mice are more similar to one another than any of them is to a catfish. This pattern of nested similarity was recognized more than 200 years ago and used by the Swedish

naturalist Carolus Linnaeus to classify all life on Earth. A century later, Charles Darwin recognized this pattern as the expected outcome of a process of “descent with modification,” or evolution.

The process of evolution can be visualized as an evolutionary tree. Evolutionary trees provide a visual model of the past and show us how all the species alive today are related to one another. In this module, we will discuss how we can use the traits of living organisms to work backward and build an evolutionary tree that describes what happened over time. We will discuss both how to read a tree and how to build a tree given a

set of species. Finally, we will put evolutionary trees to practical use and learn how they can be used to solve problems.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Think about what is possible for scientists to learn about the evolutionary history of a species and how species are related from a phylogenetic tree.

46.1 The history of life on Earth can be described as a branching tree

Darwin recognized that the species he observed were the modified descendants of earlier species. Distinct populations of an ancestral species separate and diverge through time, again and again, giving rise to

multiple descendant species through the evolutionary processes we explored in earlier modules. The result is the pattern of nested similarities observed in nature. The evolutionary history showing the relatedness of a group of organisms is called a **phylogeny**. A phylogeny is much like the genealogy that records our own family histories. We introduced phylogenetic trees in Module 40. In this section, we will look at them more closely and describe how scientists use them.

Phylogenetic Trees

As you learned in Module 40, a phylogenetic tree is a visual

representation of the evolutionary history of organisms over time. Phylogenetic trees can also be called phylogenies, evolutionary trees, or simply trees. The tree in **FIGURE 46.1** is a phylogenetic tree of chimpanzees, humans, and cows. In this tree, time runs from left to right, from the root of the tree to the tips of the branches. The root, which is at the base of the tree, represents the common ancestor of all the groups represented in the tree, and the tips of the branches represent the descendants of that ancestor. As you move from the root of a phylogenetic tree to the tips, you are moving forward in time.

FIGURE 46.1 A phylogenetic tree of chimpanzees, humans, cows, and

their ancestors

In this tree, time runs from left to right, from the root to the tips of the branches. Nodes represent common ancestors.

The groups of interest are listed at the tips of the branches. These groups, called taxa (singular, taxon), can be any group of organisms, including individuals, species, or even domains. In Figure 46.1, the three taxa are chimpanzees, humans, and cows. The point on a phylogenetic tree where a branch splits is a node. A node represents the common ancestor from which the descendant species diverged, and therefore also the time

when one species split into two.

A phylogenetic tree shows us the evolutionary history of groups of organisms, and it also illustrates how they are related to one another. The more recent the common ancestor—which is indicated by a node—the more closely related two groups are to each other. **FIGURE 46.2** shows that humans and chimpanzees share a more recent common ancestor (about 7 million years ago) than humans and cows (about 95 million years ago). This means that humans and chimpanzees are more closely related to each other than either is to cows. Groups that are more closely related to each other than to any other group

on the tree are sister groups. For example, in Figure 46.2, chimpanzees and humans are sister groups, indicated in red.

FIGURE 46.2 Close and distant relationships on a phylogenetic tree

Humans and chimpanzees are sister groups, indicated in red; they are more closely related to each other than either is to cows because they share a more recent common ancestor with each other than they share with cows.

Nodes in a phylogenetic tree can be rotated without changing the evolutionary relationships of the taxa. In the tree of humans, chimpanzees,

and cows, for example, humans can be placed above chimpanzees simply by rotating the node where the chimpanzee and human lines diverge, as shown in **FIGURE 46.3**. Evolutionary relatedness is determined by following nodes from the root to the tips of the tree, rather than by reading the order of the tips on the page. In other words, what matters is the branching order over time: the line that leads to cows branches off the line that leads to chimpanzees and humans earlier than the chimpanzee line and human line branch off from each other. What's not important is the order of the taxa on the page (from top to bottom or bottom to top in this tree),

as this arrangement can be changed by rotating nodes.

FIGURE 46.3 Rotating nodes

Nodes can be rotated without changing evolutionary relationships. The node representing the common ancestor of humans and chimpanzees has been rotated in this tree compared to that in Figure 46.2. Notice that the branching order over time is the same here as in Figure 46.2, but the order of the taxa is different along the tips of the branches.

In addition to rotating nodes, trees can be drawn in different styles. Some of these styles are shown in **FIGURE 46.4**. In 46.4a, time runs

from left to right, but in Figure 46.4b, time runs from right to left. In both Figures 46.4c and 46.4d, time runs from bottom to top, but the lines are horizontal or vertical in Figure 46.4c, while they are angled in Figure 46.4d. You can tell that these four trees are equivalent by following the branching order over time. In each case, if you start from the root of the tree, the first node, or branch point, separates the line that leads to cows from the line that leads to chimpanzees and humans, and the second node separates the line that leads to chimpanzees from the line that leads to humans.

FIGURE 46.4 Tree styles

All four trees show the same evolutionary relationships and history. In (a), time runs from left to right; in (b), time runs from right to left. In (c) and (d), time runs from bottom to top, but the angles of the branch points are different.

FIGURE 46.5 shows a phylogenetic tree that includes more vertebrate animals. The informal name at the end of each branch represents a group of organisms, many of them familiar. We sometimes find it useful to refer to groups of species this way, for example, “frogs,” rather than name all the individual species of frogs or list the characteristics they have in common. Remember, though,

that such named groups represent a number of species. If, for example, we could zoom in on the branch labeled “Frogs,” we would see that it consists of many smaller branches, each representing a distinct species of frog, either living or extinct.

FIGURE 46.5 A phylogenetic tree of vertebrate animals

This tree shows the evolutionary history and relationships among different groups of vertebrates.

The tree in Figure 46.5 provides information about evolutionary relationships among vertebrates. For example, it suggests that the closest

living relatives of birds are crocodiles and alligators because the two groups share a more recent common ancestor than they do with any other group. The tree also proposes that the closest relatives of all tetrapod (four-legged) vertebrates are lungfish, which are fish with lobed limbs and the ability to breathe air.

Nodes in this tree can be rotated without changing the evolutionary relationships, just like in all trees. **FIGURE 46.6** shows four trees from the larger tree in Figure 46.5, just focusing on turtles, crocodiles and alligators, and birds. Each tree is made by rotating one of the nodes of the previous tree. Although the trees

look different, they are all the same because they show the same branching order over time and therefore the same evolutionary relationships. For example, in all four trees, the closest living relatives of birds are crocodiles and alligators because the two groups share a more recent common ancestor than they do with any other group in the tree.

FIGURE 46.6 Equivalent trees

Rotating nodes does not change the evolutionary relationships of the groups. These four trees are equivalent.

A phylogenetic tree does not in any way imply that more recently evolved

groups are more “advanced” than groups that arose earlier. A modern lungfish, for example, is not more primitive or “less evolved” than an alligator, even though its group branches off the branch of the vertebrate tree in Figure 46.5 from an earlier node than the alligator group does. After all, both species are the products of the same interval of evolution since their divergence from a common ancestor.

AP® EXAM TIP

PREP FOR THE AP® EXAM

The AP® Biology Exam often uses phylogenetic trees to assess understanding of evolutionary relationships. Make sure you are

familiar with evolutionary trees and what they represent. You should be able to extract data from the trees and use the data to construct an evolutionary history of the species or taxa represented.

Phylogenetic Trees as Hypotheses

A phylogenetic tree is a hypothesis about the evolutionary history, or phylogeny, of a species. Phylogenetic trees are hypotheses because they represent the best model, or explanation, of the relatedness of organisms on the basis of existing data. As is the case with all hypotheses, as more information is

collected that supports a given tree, confidence that the tree accurately represents evolutionary relationships grows. And, like all hypotheses, if new information is not consistent with a given tree, the tree is revised.

For example, the tree in Figure 46.5 was built from careful analyses of the morphological features, such as the presence or absence of a jaw or walking legs, and molecular attributes of the species or other groups under study. In essence, a tree is a hypothesis about the order of branching events in evolution, and that hypothesis can be tested by gathering more information about anatomical and molecular traits.

What happens if different sources of data produce trees showing different evolutionary relationships? How do scientists select one of many trees? There are several ways to try to resolve conflicting evolutionary trees. The principle of parsimony, for example, states that the simplest explanation is the most likely. Applied to phylogenetic trees, we assume that the phylogenetic tree requiring the fewest evolutionary steps or changes is likely the most accurate. Over time, most features of organisms stay the same: we have the same number of ears as our ancestors, the same number of fingers, and so on.

In some cases, there is no way to

determine which evolutionary hypothesis is most likely. In these cases, all trees are considered equally likely until more data are collected to support one tree over another. Today, DNA sequencing is providing a wealth of molecular data that can be used to build and evaluate evolutionary trees. Molecular data on its own is not more accurate than morphological data, but the sheer quantity of molecular data means that scientists have high confidence in the trees that they construct to show the evolutionary history and relatedness of groups of organisms.

Classification

The nested pattern of similarities among species has been recognized by naturalists for centuries and is the basis for our modern classification system, called the Linnaean classification system. **FIGURE 46.7** shows how the classification system works for dogs. Note that as you move up from the level of species, each group includes more and more organisms. For example, closely related species are grouped into a genus (plural, genera). Closely related genera in turn belong to a larger, more inclusive branch of the tree, known as a family. Closely related families form an order, orders form a class, classes form a phylum (plural, phyla), and phyla form a kingdom,

with each more inclusive group occupying a successively larger branch on the tree. Biologists today refer to the three largest branches of the entire tree of life as domains, which were introduced in Unit 2. The three domains are Eukarya, Bacteria, and Archaea.

FIGURE 46.7 The Linnaean classification system

The levels are more and more inclusive as you move up in the classification system.

Although the Linnaean classification system was developed before Darwin proposed his theory of evolution, it

reflects, in essence, the evolutionary process over time. We can see this relationship by superimposing the classification system on an evolutionary tree of life, as shown in **FIGURE 46.8**. In this tree, we can see that closely related species belong to the same genus; closely related genera belong to the same family; and so on.

FIGURE 46.8 Relationship between the Linnaean classification system and the evolutionary process

Classification reflects our understanding of phylogenetic relationships, and the groupings reflect the order of branching.

Cladograms

Up to this point, we have used the word “group” to mean all the species at some taxonomic level, such as a genus or family. A different way to group organisms is by reference to their common ancestor. A clade, also called a monophyletic group, is a group of organisms that includes a common ancestor and all of its descendants. For example, consider the group labeled Amphibians in Figure 46.5. Amphibians are monophyletic because all of the groups classified as amphibians share a common ancestor not shared by any other taxa.

In contrast, consider the group of animals traditionally recognized as reptiles in Figure 46.5, which includes turtles, snakes, lizards, crocodiles, and alligators. Traditionally, birds were not considered reptiles, although they share a common ancestor with the included animals. The traditional group reptiles is paraphyletic, meaning that it includes some, but not all, of the descendants of a common ancestor. However, if we make one large group that includes birds, turtles, snakes, lizards, crocodiles, and alligators, that group is monophyletic because it includes a common ancestor and all of its descendants. This group (birds + traditional reptiles) is called

sauropsids.

There is a simple way to distinguish between monophyletic and paraphyletic groups, which is illustrated in **FIGURE 46.9**. If you need to make only one cut to separate a group from the rest of the phylogenetic tree, the group is monophyletic, as shown in blue in the figure. The group amphibians is a clade because only one cut separates it from the tree. If you need to make two cuts to separate the group from the rest of the tree, the group is paraphyletic, as shown in green in Figure 46.8. The group reptiles requires two cuts to separate it from the tree because birds are

traditionally not considered to be reptiles. Therefore, the traditional group reptiles is not a clade.

FIGURE 46.9 Clades

Only clades, or monophyletic groups, reflect evolutionary relationships because only they include all the descendants of a common ancestor.

Identifying clades is a major goal of phylogenetics because they include all descendants of a common ancestor and only the descendants of that common ancestor. As a consequence, clades alone show the evolutionary path a given group has taken since its origin. Omitting some

members of a group, as in the case of reptiles and other paraphyletic groups, can provide a misleading sense of evolutionary history. By referencing clades, we effectively convey our knowledge of their evolutionary history.

A **cladogram** is a type of evolutionary tree based on clades. Some biologists use the terms “phylogenetic tree” and “cladogram” interchangeably. Some biologists, however, make a distinction between the two types of trees. In a phylogenetic tree, the lengths of the branches may be drawn proportional to the amount of time that elapsed, whereas in a cladogram, the branch lengths are

arbitrary.

The amount of time represented by the length of a branch can be determined in some cases by finding a fossil that represents the common ancestor of two groups. Alternatively, scientists can use the number of DNA sequence differences between two groups to estimate the time that they have been separated from each other. The more time that has elapsed since two groups have separated, the more opportunities for different mutations to occur in the two groups and for them to spread throughout the populations, so the DNA sequences will be more different in the two groups. The less time, the more

similar the DNA sequences of the two groups will be. As we saw in Module 44, using DNA sequence differences between two groups to measure the time since they shared a common ancestor is known as a molecular clock.

✓ Concept Check

1. **Identify** the parts of a phylogenetic tree.

2. **Explain** why you should not read a phylogenetic tree by looking at the order of taxa along the tips.

3. **Describe** a clade.

46.2 Shared traits are present in more than one species

Phylogenetic trees are built by comparing traits, or *characters,* of different groups of organisms. **Characters** are the anatomical, physiological, or molecular features that make up organisms. In general, characters have several observed conditions, called character states.

In the simplest case, a character can be present or absent. For example, lungs are present in tetrapods and lungfish, but absent in other vertebrate animals. Alternatively, there may be multiple character states for a given trait. Petals are a character of flowers, for example, and each observed arrangement—petals arranged in a helical pattern, petals arranged in a whorl, or petals fused into a tube—can be considered a state of the character of petal arrangement.

Characters sometimes present in two or more groups of organisms. In this case, they are considered **shared characters**. Shared characters arise

for one of two reasons. The character may have been present in the common ancestor of the two groups and retained over time. In other words, the character is shared because of common ancestry. Alternatively, the character may have evolved independently in the two groups as an adaptation to similar environments. In other words, the character is shared because of convergent evolution, which is discussed in Module 41. As we saw in Module 44, characters that are similar because of common ancestry are homologous, or a homology among different species. Characters that are similar due to convergent evolution are analogous, or an analogy among

different species.

Consider two examples. Mammals and birds both produce amniotic eggs, which are water-tight eggs that allow reproduction on land. Amniotic eggs occur only in groups descended from the common ancestor at the node connecting the mammal and sauropsid branches of the tree shown in **FIGURE 46.10**. Thus, we reason that birds and mammals each inherited this character from a common ancestor in which the amniotic egg first evolved. The other sauropsids inherited this trait from the same common ancestor.

FIGURE 46.10 Homology and analogy

A homology is a similarity that results

from shared ancestry, such as the amniotic egg in sauropsids and mammals. An analogy is a similarity that results from convergent evolution, such as wings in birds and bats.

Now let's consider a second example. Wings are a character shared by birds and bats. Much evidence supports the view that wings in these two groups do not reflect descent from a common, winged ancestor; instead, wings evolved independently in the two groups as adaptations to their environments. Notice in Figure 46.10 that wings are shown twice, indicating that they evolved separately and independently in birds

and bats. They are the result of convergent evolution.

We know of many examples of convergent evolution less dramatic than wings. In some cases, we understand the genetic basis of the convergence. For example, some organisms use echolocation to locate objects in their surroundings by emitting sounds and interpreting the patterns of echoes. Echolocation has evolved in both bats and dolphins, but not in most other mammals. Echolocation requires a protein called prestin. Prestin is in the hair cells of mammalian ears and is involved in hearing ultrasonic frequencies. Bats and dolphins independently evolved

similar changes in their prestin genes, apparently convergent adaptations for echolocation. Similarly, unrelated fishes that live in freezing water at the poles, Arctic and Antarctic, have evolved similar glycoproteins that act as molecular "antifreeze," preventing the formation of ice in their tissues. They evolved this trait independently, so it's an example of an analogy in these fishes.

A phylogenetic tree can help you see the difference between homologous and analogous traits. If a trait appears once in the tree and then is maintained over time, it's a homology among the descendant species. If a trait appears more than once, it

evolved multiple times and is an analogy among the descendant species. Both types of traits can be seen in Figure 46.10.

How do scientists determine whether a shared trait among different species is homologous or analogous? Typically, they weigh evidence that suggests where other traits place the two organisms on a phylogenetic tree, look at where on the organisms the trait occurs, and examine the anatomical or genetic details of how the trait is constructed. Wings in birds and bats are similar in morphological position—both are modified forelimbs. However, wings in the two differ in details of

construction. For example, the bat wing is supported by long fingers, while the bird wing is formed by the entire forelimb. Moreover, all other traits of birds and bats place them at the tips of different lineages, with many nonwinged species between them and their most recent common ancestor. Collectively, these pieces of information suggest that bats and birds did not retain wings from a common ancestor, but rather evolved wings independently.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be able to articulate the differences between analogous and homologous structures.

✓ Concept Check

4. **Describe** why two species might share the same characteristic or trait.

5. **Describe** similarities and differences between homologous traits and analogous traits.

46.3 Evolutionary trees can be built in several ways

Up to this point, we have focused on how to read a phylogenetic tree. But how do we infer evolutionary history from a group of organisms? That is, how do we actually build a phylogenetic tree? Biologists use traits or characteristics of organisms to figure out their relationships. These traits can be morphological, such as legs, wings, feathers, and so on. Traits can also be developmental, for example, three germ layers or the amniotic egg. Finally, scientists can use molecular traits, such as specific nucleic acid or protein sequences.

In this section, we will discuss two different ways that evolutionary trees can be built given the traits of living

organisms. The first approach uses homologies and the second approach uses overall similarity.

Shared, Derived Characters

Similarities among organisms are particularly important for building trees because they sometimes suggest shared ancestry. However, a key principle of constructing trees is that only some similarities can actually tell us about evolutionary relationships among species. Other similarities can be misleading. We have already seen that homologous traits reflect inheritance from a common ancestor and therefore are

useful for building trees. Analogous traits arise by convergent evolution, so are not useful for building trees.

In addition, it turns out that only some homologies are useful for building trees. For example, character states that are unique to a given species or clade can't tell us anything about its sister group. Because they evolved after the divergence of the group from its sister group, they can be used to characterize a group but not to relate it to other groups. Consider wings again: we know that wings evolved in an ancestor of bats, but they do not occur in any other mammal. Because no other mammal has wings, this character cannot tell

us which mammalian group is the sister group to bats.

Similarly, homologies formed in the common ancestor of the entire group and therefore present in all its descendants do not help to identify sister-group relationships among the descendants of that common ancestor. All bats have wings, so wings by themselves do not help us to sort out evolutionary relationships among different bat species. To build phylogenetic trees, we need homologies that are shared by some, but not all, of the members of the group under consideration.

A **derived character** state is an

evolutionary innovation, such as the change from five toes to a single toe—the hoof—in the ancestor of horses and donkeys. When this kind of novelty arises in the common ancestor of two taxa, it is shared by both and is known as a synapomorphy. The hoof is a synapomorphy, or shared derived character, defining horses and donkeys as sister groups.

The opposable thumb is a derived trait found in both humans and chimpanzees. This shared trait indicates that humans and chimpanzees have a more recent common ancestor than either group has with cows, which don't have

opposable thumbs. The opposable thumb was an evolutionary innovation in the lineage that eventually produced humans and chimpanzees and is therefore shared by both humans and chimpanzees.

FIGURE 46.11 illustrates the major shared derived characters that have helped us construct the phylogeny of vertebrates. For example, the lung is a character present in lungfish and tetrapods, but absent in other vertebrates. The presence of lungs provides one piece of evidence that lungfish are the sister group of tetrapods.

FIGURE 46.11 Shared derived characters of vertebrate animals

Homologies that are present in some, but not all, members of a group are called shared derived characters and they can be used to construct phylogenetic trees.

Building a phylogenetic tree on the basis of shared derived characters is called cladistics. **FIGURE 46.12a** uses cladistics to build a phylogenetic tree of horses, humans, and lizards. Humans and horses are both mammals with many shared derived traits, such as mammary glands, hair, and three middle ear bones. Humans and horses are therefore more closely related to each other than either is to lizards. Put another way, humans and

horses share a more recent common ancestor than either shares with lizards.

FIGURE 46.12 Phylogenetic trees of horses, humans, and lizards

These two phylogenetic trees were built using shared derived traits. (a) This tree was constructed using the shared derived traits of mammary glands, hair, and three middle-ear bones. (b) This tree was constructed using the shared derived trait of warm bloodedness.

We can also use blood temperature to build a tree that includes humans, horses, and lizards. Humans and horses are warm-blooded, that is,

they maintain a relatively stable body temperature; lizards are cold-blooded, that is, they have a body temperature that changes with the environment. Warm bloodedness is a shared derived trait; it is shared by horses and humans because it arose in a mammal from which both are descended. Based on their common physiological trait, humans and horses are placed together as they are in Figure 46.12b, which is the same tree as in Figure 46.12a. Using shared derived characters for phylogenetic reconstruction is the foundation of the cladistics approach.

Warm bloodedness is a more recent trait in evolutionary history that is

derived from the older, ancestral condition of cold bloodedness. In a cladistics-based approach, scientists determine whether a particular trait is ancestral or derived, and then use shared derived traits when building a tree. Consider again the number of fingers in humans and horses. How do scientists know that five fingers is ancestral and one finger (the hoof) is derived, and not the other way around? One way to answer this question is by looking in the fossil record. The phylogenetic tree shown in **FIGURE 46.13** illustrates a human, a horse, and *Proterogyrinus,* a four-legged vertebrate (tetrapod) that is a common ancestor of horses and humans. Because the common

ancestor of horses and humans had five fingers, we infer that five fingers is ancestral and the single hoof of horses is derived.

FIGURE 46.13 The evolution of hooves and hands from a five-fingered tetrapod

Because the fossil organism *Proterogyrinus* had five fingers, we infer that five fingers is the ancestral state and one finger (the hoof) is the derived state.

What if there are no available fossils? How do scientists determine whether a trait is ancestral or derived? In this case, they can make an *outgroup*

comparison. An **outgroup** is a taxon whose common ancestor with the group of interest, known as the ingroup, is older than the common ancestor of the group of interest. Outgroup comparison is based on the idea that traits are more likely to stay the same than they are to change. For this reason, scientists expect an outgroup to have preserved the ancestral state in most instances.

If the group of interest includes horses and humans, an outgroup can be lizards, as shown in **FIGURE 46.14**. Lizards can serve as an outgroup for horses and humans because the common ancestor of lizards, humans, and horses, indicated by the node

CA1 on the tree, is older than the common ancestor of humans and horses, indicated by the node CA2 on the tree. Because the outgroup—the lizard—has five fingers, you can conclude that having five fingers is the ancestral state and having one finger (a hoof) is the derived state. Note that this is the same answer at which we arrived by looking at the fossil record. In science, when two different approaches or datasets give you the same answer, scientists have more confidence in the result.

FIGURE 46.14 Outgroup comparison

The lizard is considered an outgroup with respect to humans and horses because the common ancestor of lizards

and humans/horses (CA1) is older than the common ancestor of humans and horses (CA2).

So far, we have seen how morphological traits, such as the number of fingers, and physiological traits, such as blood temperature, are used to build evolutionary trees. Today, biologists typically use molecular data to build trees. The data are different, but the logic is the same. The sequence of amino acids of a protein can be used for this purpose, as can the nucleotides along a strand of DNA.

From genealogy to phylogeny, tracing

mutations in DNA or RNA sequences has revolutionized the reconstruction of historical genetic connections. Whether we are tracing the paternity of the children of Sally Hemings, the mother of several of Thomas Jefferson's children; identifying the origin of a recent cholera epidemic in Haiti; or placing whales in a phylogenetic tree of mammals, molecular data are a rich source of phylogenetic insight.

Molecular data do not provide an intrinsically better record of history than anatomical data; molecular data simply provide more information because there are more characters that can vary among the species. A

sequence of DNA with hundreds or thousands of nucleotides can represent that many characters, as opposed to the tens of characters usually visible in morphological studies. For microbes and viruses, for example, very little morphology is available, so molecular information is critical for building trees. Once a gene or other stretch of DNA or RNA is identified that seems likely to vary among the species to be studied, sequences are obtained and aligned to identify homologous nucleotide sites. Analyses of this kind commonly involve comparisons of sequences of about 1000 nucleotides from one or more genes.

Increasingly, though, the availability of whole-genome sequences is changing the way we do molecular phylogenetics. With this approach, rather than comparing the sequences of a few genes, we compare the sequences of entire genomes. The process of using molecular data is conceptually similar to the process described earlier for morphological data. Through comparison to an outgroup, we can identify shared derived molecular characters, whether DNA nucleotides or amino acids in proteins, and generate the phylogeny on the basis of synapomorphies as before.

Distance Methods

We have seen that phylogenetic trees can be built using shared derived traits. An alternative approach to building phylogenetic trees is based on overall similarity. With this approach, the assumption is that the descendants of a recent common ancestor will have had relatively little time to evolve differences, whereas the descendants of an ancient common ancestor have had a lot of time to do so. Thus, the extent of similarity indicates how recently two groups shared a common ancestor.

Biologists measure similarity using some measure of distance between the two species, such as morphological (anatomical) similarity

or the number of base pair differences between DNA sequences. In other words, according to this distance-based approach, the more similar two species appear or the more similar their DNA sequences are, the more closely related they are.

This distance-based approach works well in some cases. For example, humans and chimpanzees appear more similar to each other than humans appear to cows, so we conclude that humans and chimpanzees share a more recent common ancestor than humans share with cows. Humans and chimpanzees have had less time to evolve differences and therefore appear

similar to each other. Humans and cows have had more time to evolve differences and therefore look quite different from one another.

Note that this distance-based approach works for molecular analysis of humans, chimpanzees, and cows, too: for a given gene, there are fewer base pair differences between humans and chimpanzees than there are between humans and cows.

FIGURE 46.15 shows how distance methods work, using great apes and molecular traits. In the top part of the figure, we see DNA sequences for humans, chimpanzees, gorillas, and

gibbons. The bases in black are the same in all four species; the bases in red are variable. We then count the number of base differences between each pair of species. For example, the human and chimp sequences differ at two nucleotides, and the human and gorilla sequences differ at four nucleotides. We continue to compare the DNA sequences of all pairs of species, and then record the number of sequence differences in the following table the sequences. Those with the fewest differences are considered to be most closely related; those with a greater number of differences are considered to be more distantly related. Therefore, we build the tree starting with humans and

chimps because they have the fewest differences. Then we add gorillas, and so on. In the end, we have a phylogenetic tree that includes all four species on the right side of the figure.

FIGURE 46.15 Building a phylogenetic tree using distance methods

Sequence data can be used to reconstruct phylogeny on the basis of distance, where distance is measured in the number of sequence differences between species.

Underpinning this approach is the assumption that the rate of evolution, or change, is more or less constant in

different groups. If evolutionary rates vary, then we can't use this approach because it can produce an incorrect tree. Consider the tree in **FIGURE 46.16a**. As you can see in the tree, sharks and rays are more closely related to each other than either of them is to the other major group of living fishes, called bony fish. If you were to use distance measures to build a tree, you could focus on morphological similarity among sharks, rays, and bony fish. Because sharks and bony fish have similar body forms, you would conclude, incorrectly, that sharks and bony fish have a more recent common ancestor and are therefore more closely related than sharks and rays, as shown in

Figure 46.16b.

FIGURE 46.16 Correct and incorrect phylogenetic trees of sharks, rays, and bony fish

Distance measures sometimes produce an incorrect tree. (a) This tree correctly indicates that sharks are more closely related to rays than sharks are to bony fish. Note that sharks and rays share a more recent common ancestor than sharks and bony fish do. (b) This incorrect tree assumes that sharks are more closely related to bony fish than sharks are to rays because sharks look very similar to bony fish but very different from rays.

This is a case in which distance measures have resulted in the incorrect tree. What went wrong? The distance-based approach assumes that evolution proceeds at equal or constant rates in different groups over time. However, in this example, new morphological traits appeared relatively quickly in the line that led to rays, indicated by the red lines along the branches of the tree in **FIGURE 46.17**, and much more slowly in the lines that led to sharks and bony fish. As a result, rays look very different from sharks, even though rays and sharks are actually closely related to each other.

FIGURE 46.17 Varying rates of evolution in different groups

Many new morphological traits, indicated by the red lines, appeared in the line that led to rays, and fewer appeared in the lines that led to sharks and rays, which explains why a distance approach does not work in this case.

In other words, the mistake stems from grouping sharks and bony fish together on the basis of neither of them having changed very much over time. Rays, in contrast, have changed a great deal. So even though sharks and bony fish look more similar to each other than either of them looks like rays, sharks are actually more closely related to rays than they are to bony fish. In this case, looks are

deceiving.

This type of problem is often less of an issue with molecular data than it is with morphological data. As a result, distance-based measures are commonly used to build phylogenetic trees with data obtained from DNA sequencing.

AP® EXAM TIP

PREP FOR THE AP® EXAM

When describing an evolutionary relationship between taxa or groups, be sure to use morphological, fossil, and molecular data whenever possible.

✓ Concept Check

6. **Describe** two different ways to build evolutionary trees.

7. **Describe** why molecular traits are useful when building trees.

46.4 Phylogenetic trees can help solve practical problems

The sequence of changes on a tree from its root to its tips documents evolutionary changes that have accumulated through time. Trees

suggest how species are related to one another, and which traits came first and which followed later. Building phylogenetic trees, therefore, reveals a great deal about evolutionary history.

It can have practical uses as well. For example, oomycetes, which are the microorganisms responsible for potato blight and other important diseases of food crops, were long thought to be fungi because they look like some fungal species. The discovery, using molecular characters, that oomycetes belong to a very different group of eukaryotic organisms has opened new possibilities for understanding and

controlling these plant pathogens.

Similarly, in 2006, researchers used DNA sequences to identify the Malaysian parent population of a species of butterfly called lime swallowtails that have become an invasive species in the Dominican Republic, pinpointing the source populations from which natural predators of this pest can be sought.

Phylogenetics was also employed to solve a famous case in which a dentist in Florida was accused of infecting his patients with human immunodeficiency virus (HIV). HIV nucleotide sequences evolve so rapidly that biologists can build

phylogenetic trees that trace the spread of specific strains from one individual to the next. Phylogenetic study of HIV present in samples from several infected patients, the HIV-positive dentist, and other individuals provided evidence that the dentist had, indeed, infected his patients, as described in "Practicing Science 46.1: Did an HIV-positive dentist spread the AIDS virus to his patients?"

Practicing Science 46.1

Did an HIV-positive dentist spread the AIDS virus to his patients?

PREP FOR THE AP® EXAM

Background In the late 1980s, several patients of a Florida dentist contracted acquired immunodeficiency syndrome (AIDS), the disease caused by HIV infection. Molecular analysis showed that the dentist was HIV-positive.

Hypothesis It was hypothesized that the patients acquired HIV during dental procedures carried out by the infected dentist.

Method Researchers obtained two HIV samples each, denoted 1 and 2 in the following figure from several people. Samples were obtained from the dentist, denoted Dentist 1 and Dentist 2; several of his patients, denoted Patients A through G; and other HIV-positive individuals chosen at random from the local population, denoted as LP

followed by numbers to indicate different people. In addition, a strain of HIV from Africa (HIVELI) was included in the analysis as an outgroup.

Results Biologists constructed a phylogeny based on the nucleotide sequence of a rapidly evolving gene in the genome of HIV. Because the gene evolves so quickly, its mutations preserve a record of evolutionary relatedness on a very fine scale. The HIV samples taken from some of the infected patients—patients A, B, C, E, and G—were more closely related to the dentist's HIV than they were to samples taken from other infected individuals. Some patients' sequences, however, were different enough from the dentist's

that they were not on the same part of the tree, suggesting that these patients, D and F, had acquired their HIV infections from other sources.

Conclusion HIV phylogeny makes it highly likely that the dentist infected several of his patients. The details of how the patients were infected remain unknown, but the safety practices now rigidly observed in dentistry make it unlikely that such a tragedy could occur again.

Follow-up Work Phylogenies based on molecular sequence characters are now routinely used to study the origin and spread of infectious diseases, such as swine flu and Ebola.

Cunningham. 1994. “Application and Accuracy of Molecular Phylogenies.” *Science* 264:671–677.

AP® PRACTICE QUESTION

In Unit 6, you learned that the processing of genetic information is not perfect and results in genetic variation. One method utilized to construct a phylogenetic tree like the one shown is to score the degree of similarity between sequences of nucleotides. **Explain** the evolution of the HIV virus based on the placement of patients D-1, C-1, and C-2 relative to Dentist 2 in terms of their corresponding nucleotide sequences by answering the following:

a. **Make a claim** identifying which of the three patients were infected by Dentist-2.

b. **Justify** your claim with evidence based on the placement of each patient in the tree.
c. **Provide reasoning** for your claim based on the evolution of nucleotide sequences over time.

Similarly, phylogenetic studies of influenza virus, which causes the flu, and SARS-CoV-2, which causes COVID-19, have been used to determine where strains and variants originate and their subsequent movements among geographic regions and individual patients. Today, there is a growing effort to use specific DNA sequences as a kind of fingerprint or barcode for tracking biological material. These efforts rely on the DNA sequencing techniques

described in Module 38. Such information could quickly identify samples of shipments of meat as being from endangered species or track newly emerging pests. The Consortium for the Barcode of Life has already accumulated species-specific DNA barcodes for more than 100,000 species. Phylogenetic evidence provides a powerful tool for evolutionary analysis and is useful across timescales ranging from months to the entire history of life, from the rise of pandemics to the origins of metabolic diversity.

✓ Concept Check

8. **Identify** the type of trait (morphological, developmental, or

molecular) that is used to track HIV or influenza samples and build trees.

9. **Describe** one practical use of building evolutionary trees.

Module 46 Summary

REVISIT THE BIG IDEAS

EVOLUTION: Use the content of this module to **describe** two types of evidence that can be used to determine placement of a species on a phylogenetic tree.

LG 46.1 The history of life on Earth can be described as a branching tree.

- The nested pattern of similarities seen among organisms is a result of descent with modification and can be represented as a phylogenetic tree. Page 645
- A node is a branching point on a phylogenetic tree; it represents a common ancestor and it can be

rotated without changing evolutionary relationships. Page 646

- Sister groups are more closely related to one another than they are to any other group. Page 646
- Evolutionary relatedness is determined by following the sequence of nodes on a phylogenetic tree over time; more closely related groups share more recent common ancestors than more distantly related groups. Page 646
- A phylogenetic tree is a hypothesis or model of the evolutionary relationships among organisms. Page 648
- Organisms are classified into

species, genus, family, order, class, phylum, kingdom, and domain. Page 648

- A monophyletic group, or clade, includes a common ancestor and all of its descendants. Page 649
- A paraphyletic group includes a common ancestor and some, but not all, of its descendants. Page 649
- A cladogram is a phylogenetic tree that shows clades, or monophyletic groups. Page 650

LG 46.2 Shared traits are present in more than one species.

- Shared character states are sometimes used to build phylogenetic trees. Page 651

- Homologies are similarities based on common ancestry. Page 651
- Analogies are similarities based on convergent evolutions. Page 651

LG 46.3 Evolutionary trees can be built in several ways.

- A phylogenetic tree can be built on the basis of shared derived characters. Page 652
- Molecular data, such as DNA sequences, provide a wealth of characters that complement other types of information in building phylogenetic trees. Page 655
- A phylogenetic tree can also be built by looking at overall similarity in form or molecular

sequences. Page 655

LG 46.4 Phylogenetic trees can help solve practical problems.

- Phylogenetic trees can be used to understand evolutionary relationships of organisms. Page 657
- They can also be used to solve practical problems, such as how viruses evolve over time. Page 657

Review Questions

1. The evolutionary history of a group of organisms is called a

A. phylogeny.
B. taxonomy.
C. morphology.
D. fossil.

2. A group that includes a single common ancestor and all its descendants is

A. monophyletic.
B. paraphyletic.
C. polyphyletic.
D. phyletic.

3. Which statement is true regarding phylogenetic trees?

A. Phylogenetic trees can be considered physical representations of hypotheses that seek to establish the evolutionary relationships between different organisms.
B. Given the sheer number of species on Earth, it is impossible to create a phylogenetic tree encompassing all of these organisms.
C. Phylogenetic trees are constructed based solely on the morphological characteristics of species, not molecular characteristics.
D. Within a phylogenetic tree, the order of groups located at the

tree tips determines evolutionary relationships.

4. The nodes on a phylogenetic tree represent

A. sister groups.
B. descendant lineages.
C. common ancestors.
D. present-day groups.

5. Two taxa that are more closely related to each other than to any other taxon are called

A. sister groups.
B. paraphyletic groups.
C. homologous groups.
D. analogous groups.

6. If two organisms are in the same

class, then which of the following must also be true?

A. They are in the same phylum.
B. They are in the same family.
C. They are in the same genus.
D. They are in the same order.

7. Traits that are similar in two species as a result of common ancestry are referred to as

A. convergent.
B. analogous.
C. homologous.
D. derived.

Module 46 AP® Practice Questions

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

Use the following figure to answer question 1.

1. Which tree indicates an evolutionary relationship that is different from the others?

   A. a
   B. b
   C. c
   D. d

Use the following figure to answer question 2.

1. *Ceratitis capitata* is a species of fruit fly that lives in the Mediterranean region of the world. Multiple times in its history, *C. capitata* has been accidentally transported to other parts of the world with shipments of produce. The imported *C. capitata* establish new, reproductively isolated populations in each new location. A team of scientists used DNA sequences to study the evolutionary relationships among *C. capitata* captured around the

world between 1992 and 2002, and constructed the tree shown. Based on the tree, what is most likely the number of times that Australia was invaded by the Mediterranean population of *C. capitata*?

A. 1
B. 2
C. 3
D. 4

Questions 3 and 4 refer to the following figure, which illustrates the evolutionary relationships among seven species, labeled J–P.

1. Which species is most closely

related to species M?

A. Species J
B. Species K
C. Species L
D. Species P

2. Which species is the outgroup on the phylogenetic tree?

A. Species J
B. Species L
C. Species M
D. Species P

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples.

Where calculations are required, show your work.

The figure illustrates the evolutionary relationships between major plant groups. Key traits are indicated with letters on the phylogeny.

a. **Identify** the outgroup relative to all other organisms in the tree.
b. **Describe** which node represents the common ancestor between lycophytes and monocots.
c. **Determine** how long ago gymnosperms and dicots shared a common ancestor.
d. **Identify** which trait is shared by monocots, dicots, and

gymnosperms but is absent from all other plants.

e. **Identify** which plant group is vascular and produces flowers and seeds for reproduction, but does not have reticulate leaf venation.

Module 47

Speciation

LEARNING GOALS

- **LG 47.1 Species are reproductively isolated from other species.**
- **LG 47.2 Reproductive isolation is caused by barriers to reproduction before or after fertilization.**
- **LG 47.3 New species arise by the process of speciation.**

In the last module, we discussed phylogenetic trees. These trees provide a visual model or

representation of the evolutionary history of different groups of organisms. They also illustrate how organisms are related to one another: species that share a more recent common ancestor are more closely related to each other than those that share a more ancient common ancestor.

Phylogenetic trees have a root at the base; branches that proceed from the past to the present; and tips of the branches, where we place groups of organisms, called taxa. The branches split into two at points called nodes. In the last module, we described these nodes as representing common ancestors. That is, if you move

forward in time from a node, you can find the various organisms that descended from this common ancestor. Nodes split into two branches, so they also represent events where one species gives rise to two separate species. In this module, we will take a closer look at these places of divergence.

We will begin by examining the concept of species. In the Linnaean classification scheme introduced in Module 46, a species is the smallest, least inclusive group of organisms. However, this is not a very precise definition, so we will discuss in more detail what it means to be a member of a species. Then we will consider

why species are distinct from one another and what prevents them from merging into one large group of organisms. Finally, we will discuss the process by which one species becomes two species, the point on a phylogenetic tree where one branch splits into two.

47.1 Species are reproductively isolated from other species

The definition of "species" has been a long-standing subject of debate in biology. In *On the Origin of Species,* Darwin wrote, "No one definition has as yet satisfied all naturalists; yet every naturalist knows vaguely what he means when he speaks of a species." The difficulty of defining species has come to be called the species problem.

Here is the problem in a nutshell. The key point of the Darwinian revolution is that species are not fixed and unchanging. Therefore, a species must be fluid and capable of changing

in a way that gives rise through evolution to new species. Yet how can we establish a fixed definition of the concept of species if a species can change over time, sometimes enough to create something entirely different—a new species? In this section, we will look at different ways to think about the concept of species.

The Biological Species Concept

We can plainly see the diversity of organisms all around us. When we call a group of organisms a species, is it a separate biological entity or are we using the term as just a convenient way to organize the natural world? To

test whether the concept of species reflects reality, we can start by examining characteristics of different living organisms we see in the natural world. **FIGURE 47.1** shows a graph that plots antenna length and wing length of three different types of butterflies that appear to be different. Note that the dots, which represent individual organisms, fall into non-overlapping clusters. The fact that the clusters are distinct implies that each cluster is a biologically distinct species.

FIGURE 47.1 Comparing characteristics of species

When we graph two characteristics, such as antenna length and wing length, for

different species of butterflies, we find that they fall into discrete clusters, which suggests that species are real biological groupings.

While the data points in Figure 47.1 cluster into three distinct groups, we also see distances between dots within each cluster. These distances reflect variations among individuals within a species. Similarly, humans are more similar to one another than to our most humanlike relative, the chimpanzee, and also, within the group, humans are highly variable. On a plot such as the one in Figure 47.1, humans would form a messy cluster, but that cluster would not

overlap with the chimpanzee cluster.

Species, then, are real biological entities, not just a way to group organisms. The definition of "species" continues to be debated to this day. The most widely used and generally accepted definition of a species is known as the *biological species concept*. The **biological species concept (BSC)** was described by the evolutionary biologist Ernst Mayr as follows:

> *Species are groups of actually or potentially interbreeding populations that are reproductively isolated from other such groups.*

Let's look at this definition closely. At its heart is the idea of reproductive compatibility. Members of the same

species are capable of producing offspring, whereas members of different species are incapable of producing offspring. Therefore, members of different species are reproductively isolated from one another.

As Mayr and many others realized, however, reproductive compatibility entails more than just the ability to produce offspring. The offspring must be fertile and, therefore, capable of passing their genes on to their own offspring. For example, although a horse and a donkey—which are two different species—can mate to produce a mule, the mule is infertile. If a hybrid offspring is

infertile, then it represents a genetic dead end.

Note, too, the part of Mayr's definition that indicates species are groups that can potentially interbreed. Consider an Asian elephant living on the island of Sri Lanka and one living in nearby India, pictured in **FIGURE 47.2**. These two elephants are considered members of the same species, *Elephas maximus,* even though Sri Lankan and Indian Asian elephants never have a chance to mate with each other in nature because they are geographically separated. If they were placed in the same region, they could interbreed and produce fertile offspring. In other words, they can

potentially interbreed, even if they don't actually interbreed because of their geographic separation.

FIGURE 47.2 Reproductive compatibility in Asian elephants

Asian elephants in India and Sri Lanka are considered to be the same species, even though they will never actually interbreed with each other because they don't live in the same place. However, they could potentially interbreed if they were moved to the same geographical area.

Therefore, whether two individuals are members of the same species is a reflection of whether they are able to

exchange genetic material by producing fertile offspring. Consider a new advantageous mutation that appears initially in a single individual. That individual and its offspring that inherit the mutation will have a competitive advantage over other members of the population—they will be more fit. As a result, the mutation will increase in frequency until it reaches 100%, or become fixed in the population. The mutation spreads within the species but, with some rare exceptions, cannot spread beyond it. Therefore, a species represents a closed gene pool, in which gene variants (alleles) are shared among members of that species, but usually not with members of other species.

Shortcomings of the BSC

The BSC is the most widely accepted way to define species. Nevertheless, the BSC has shortcomings. First, it can be difficult to apply. Imagine you are on a field expedition in a rainforest and you find two insects that look reasonably alike. Are they members of the same species? To use the BSC, you would need to test whether they are capable of producing fertile offspring. In practice, you probably will not have the time and resources to perform such a test. Even if you do attempt such a test, it is possible that members of the same species will not

reproduce when you place them together in a laboratory setting or in your field camp. The conditions may be too unnatural for the insects to behave in a normal way. Finally, if they do mate, you may not have time to determine whether their offspring are fertile. Thus, we consider the BSC to be a valid framework for thinking about species, but one that is difficult to apply to real-world settings.

In addition to the difficulty of putting the BSC into practice, a second problem is that it cannot be applied to all organisms. For example, because it is based on reproduction, or the sexual exchange of genetic information, the BSC does not apply

to species that reproduce asexually, such as bacteria. Furthermore, because it depends on reproduction, the BSC cannot be applied to species that are extinct and known only through the fossil record, such as different groups of trilobites and dinosaurs.

Finally, populations of one species may vary in the extent to which they are reproductively isolated from another, closely related species. In one location, the two species may be reproductively isolated from each other. At the same time, in another location, the two species might interbreed to produce fertile hybrid offspring, which in this context are

offspring produced by two different species. According to the BSC, the first pair of populations represents two species, whereas the second pair represents just one. An example is shown in **FIGURE 47.3**. Two closely related birds, the spotted towhee (*Pipilo maculatus*) and the collared towhee (*Pipilo ocai*), co-occur in various locations in Mexico. In some places they interbreed, indicated by the yellow checkers in the map; in others they do not, indicated by the orange checkers in the map.

FIGURE 47.3 Hybridization in towhee species

Bird species called towhees interbreed in some places but not in others. (a) The

two species of closely related birds, *Pipilo maculatus* and *Pipilo ocai,* produce hybrid offspring. (b) The two species overlap in places in their distributions in central Mexico. In some locations, shown in yellow checkers, they hybridize; in other locations, shown in orange checkers, they do not.

Data from Futuyma, D. J. 2009. *Evolution*, 2nd ed. Sunderland, MA: Sinauer Associates, Fig. 18.7, p. 484.

This kind of incomplete reproductive isolation seems to be especially common in plants. For example, many different species of willow, oak, and dandelion are still capable of exchanging genes with other species

in their genera, even though we call them separate species because they maintain their different appearances in spite of interbreeding. According to the BSC, these different forms should be considered one large species because they are able to reproduce and produce fertile offspring. However, because the species maintain their distinct appearances, we call them distinct species.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be able to describe the biological species concept. Remember that it does not apply to species that reproduce asexually

such as bacteria, nor can it apply to species present in the fossil record.

Other Species Concepts

Scientists have addressed the shortcomings of the BSC by modifying it and suggesting many alternative definitions of species. In general, these efforts highlight how difficult it is to make all species fit easily into one definition. The natural world truly defies neat categorization!

One alternative way of categorizing species is called the morphospecies concept, which is used by biologists on a day-to-day basis. The

morphospecies concept holds that members of the same species usually look alike. For example, the shape, size, and coloration of the bald eagle (*Haliaeetus leucocephalus*) make it reasonably straightforward to determine whether a bird observed in the wild is a member of the bald eagle species.

Today, the morphospecies concept has been extended to the molecular level. As we discussed in Module 46, members of the same species usually have similar DNA sequences that are distinct from those of other species. A remarkable project called the Barcode of Life has established a database linking DNA sequences to

species. Scientists can use it to identify species from DNA alone by sequencing the relevant segment of DNA and finding the matching sequence and therefore the species in the Barcode of Life database. Through the use of this database scientists can determine those biological clusters at the molecular level, like the morphological clusters shown in Figure 47.1 in which members of a species fall close to one another within a single, discrete group.

Although the morphospecies concept is useful and generally applicable, it is not without its own set of issues. Members of a species may not always look alike. Some species show

different phenotypes. For example, some species of birds display color differences. Sometimes, males of a species may look different from females—think of the showy peacock, which differs dramatically from the relatively drab peahen. Young can also be very different from old: caterpillars that mature into butterflies are a striking example.

We have seen that members of the same species can look quite different from one another. But it is also true that members of different species can look quite similar. For example, some species of butterfly appear similar but have chromosomal differences that can be observed only with the aid of a

microscope, as illustrated in **FIGURE 47.4**. These chromosomal differences prevent the formation of hybrid offspring, so those butterflies meet the BSC definition—they are different species because they do not interbreed—but they do not meet the morphospecies definition because they look so much alike.

FIGURE 47.4 Three species of *Agrodiaetus* butterflies

These butterflies look very similar to each other but have different numbers of chromosomes, so they are unable to interbreed, and are therefore different species.

Biologists sometimes describe species according to their ecological *niche*. An ecological **niche** is a complete description of the role the species plays in its environment and of its abiotic and biotic requirements. We will discuss the concept of niche in more detail in Unit 8. Niche can sometimes be relevant to determining species because two species can not coexist in the same location if their niches are too similar. If two very similar species attempt to exist in the same niche, competition for resources inevitably leads to the extinction of one species. This observation has given rise to the ecological species concept, the idea that there is a one-to-one

correspondence between a species and its niche.

We can apply this concept to bacteria, which don't reproduce sexually and which therefore can't be separated into different species based on the BSC. Instead, we can determine whether different bacteria are distinct species on the basis of differences or similarities in their ecological requirements. If two types of bacteria have very different nutritional needs, for example, we can infer on ecological grounds that they are separate species.

Another species concept is the phylogenetic species concept, which

emphasizes that members of a species all share a common ancestry and a common fate, like a single branch on an evolutionary tree. After all, species rather than individuals originate and become extinct. The phylogenetic species concept requires that all members of a species be descended from a single common ancestor. It can be useful when thinking about asexual species such as bacteria and archaea. However, in other cases, its usefulness is limited. For example, all mammals descend from a common ancestor, but include many species, not one.

It is worth bearing these ecological and evolutionary considerations in

mind when thinking about species. Despite the shortcomings of the BSC and the usefulness of alternative ideas, the BSC remains the most constructive way to think about species and still the most widely used and accepted among biologists. In particular, by focusing on reproductive isolation—the inability of different species to produce viable, fertile offspring—the BSC gives us a means of studying and understanding how two populations, originally members of the same species, become distinct species.

✓ Concept Check

1. **Describe** how the term "species" is defined according to the biological

species concept.

2. **Identify** two species that don't fit easily into the biological species concept, and suggest an alternative way to define them.

47.2 Reproductive isolation is caused by barriers to reproduction before or after fertilization

At the heart of the biological species concept is reproductive isolation, in which two different species cannot interbreed with each other to produce viable, fertile offspring. Factors that cause reproductive isolation are generally divided into two categories, depending on when they act relative to the zygote, which is a fertilized egg.

Prezygotic factors act before the fertilization of an egg and prevent fertilization from taking place. **Postzygotic** factors come into play after fertilization and prevent the fertilized egg from developing into a fertile individual. In this section, we will provide examples of both prezygotic and postzygotic factors that serve to reproductively isolate different species.

Prezygotic Factors

Most species are reproductively isolated by prezygotic factors, which can take many forms. Plants and animals can be isolated in space, called geographic isolation or

ecological isolation. This type of isolation can be dramatic, like two species on either side of a canyon. It can also be subtle. For example, the two Japanese species of ladybug beetle shown in **FIGURE 47.5** can be found living side by side in the same field, but they feed and mate on different plants. Because their life cycles are intimately associated with their host plants, these two species never breed with each other. This ecological separation is what leads to their prezygotic isolation.

FIGURE 47.5 Ecological isolation

The ladybugs (a) *Henosepilachna yasutomii* and (b) *H. niponica* are reproductively isolated from each other

because they feed and mate on different host plants.

Both plants and animals may also be prezygotically isolated in time, called temporal isolation. For example, closely related plant species may flower at different times of the year, so there is no chance that the pollen of one species will come into contact with the flowers of the other. Similarly, members of a nocturnal animal species are unlikely to encounter members of closely related species that are active only during the day.

Among animals, species often show behavioral isolation, meaning that

individuals mate only with other individuals based on specific courtship rituals, songs, or other behaviors. Birds of paradise in the rainforests of Southeast Asia, for example, have elaborate courtship dances that involve very specific and ritualized displays, songs, and dances. Closely related birds can have very different displays that only work within members of a species, but fail to provoke even the faintest reproductive impulse in a different species. In this case, the prezygotic reproductive isolation is behavioral.

Behavior does not play a role in plants, but prezygotic factors can still be important in their reproductive

isolation. Prezygotic isolation in plants can take the form of incompatibility between the incoming pollen and the receiving flower, such that fertilization fails to take place. We see similar forms of isolation between members of marine animals, such as abalone (a sea snail), which simply discharge their gametes into the water. In these cases, membrane-associated proteins on the surface of sperm interact specifically with membrane-associated proteins on the surface of eggs of the same species, but not with those of different species. These specific interactions ensure that a sperm from one abalone species, *Haliotis rufescens,* fertilizes only an egg of its

own species and not an egg from *H. corrugata,* a closely related species. Incompatibility between the gametes of two different species is called gametic isolation.

In some animals, especially insects, incompatibility arises earlier in the reproductive process. As an example, the genitalia of males of the fruit fly *Drosophila melanogaster* are configured in such a way that they fit only with the genitalia of females of the same species. Thus, attempts by males of *D. melanogaster* to mate with females of another species of fruit fly, *D. virilis,* are prevented by mechanical isolation.

Postzygotic Factors

Postzygotic factors involve mechanisms that come into play after fertilization of the egg. Typically, they involve some kind of genetic incompatibility between the two organisms. One example, which we saw earlier in Figure 47.4, is the case of two organisms with different numbers of chromosomes.

In some instances, the effect can be extreme. For example, the zygote may fail to develop after fertilization because the two parental genomes are sufficiently different to prevent normal development. In this case, the hybrid offspring is not viable.

In others, the effect is less obvious. Some matings between different species produce perfectly viable adults, as in the case of the horse–donkey hybrid, the mule. As we have seen, though, all is not well with the mule from an evolutionary perspective. Because horses and donkeys have different chromosome numbers, proper homologous chromosome pairing in meiosis in the mule cannot take place, resulting in infertility of the mule. In this case, the hybrid offspring is viable, but sterile.

These examples of prezygotic and postzygotic isolating mechanisms are summarized in **TABLE 47.1**.

Prezygotic factors are often considered to be more efficient than postzygotic factors because organisms do not waste the time, energy, and resources in forming and at least partially supporting an embryo when prezygotic isolating factors are in place. Nevertheless, both prezygotic and postzygotic factors present barriers to gene flow. And when there is no gene flow between groups of organisms, they are considered to be different species according to the BSC.

Isolating factor	Example	Explanation
Prezygotic	Geographic	Individuals are separated in space.
	Ecological	Individuals are separated by

		habitat or other ecological specialization.
	Temporal	Individuals are reproductively active at different times.
	Behavioral	Individuals only mate with other individuals based on specific courtship rituals, songs, or displays.
	Gametic	Gametes are incompatible and do not fuse to form a fertilized egg.
	Mechanical	Individuals are unable to mate.
Postzygotic	Hybrid inviability	Embryo forms but does not fully develop.
	Hybrid sterility	Offspring are produced but are

	sterile.

47.3 New species arise by the process of speciation

Recognizing that species are groups of individuals that are reproductively isolated from other such groups, we are now in a position to recast the key question addressed in this module. That is, instead of asking, "How do new species arise?" we can ask, "How does reproductive isolation arise between populations?" In this section we will examine **speciation**, the

process by which new species are produced. We will focus on two types of speciation, one that involves a geographic barrier that separates one population into two populations, and one that does not involve a geographic barrier. We will end with a discussion about rates of speciation in different groups of organisms.

Allopatric Speciation

The key to speciation is the fundamental evolutionary process of genetic divergence between isolated populations. **Divergent evolution** occurs when two populations of organisms become genetically and physically different from each other.

FIGURE 47.6 illustrates this process. If a single population is split into two populations that are isolated from each other, different mutations appear by chance in the two populations. Like all mutations, these are subject to genetic drift, natural selection, or both. Over time, these mechanisms lead to the genetic divergence of the two populations. Two separate populations that are initially identical will, over a long time, gradually become distinct as different mutations occur and spread through each of the populations. At some stage in the course of evolutionary divergence, changes occur in one population that lead to its members becoming reproductively

isolated from members of the other population. It is this process that results in speciation.

FIGURE 47.6 Speciation, the process by which one species becomes two species

Speciation occurs when two populations, A and B, genetically diverge until they become reproductively isolated from each other. At first, there is not enough genetic divergence and so they are able to interbreed, as indicated by the green check marks. Later, the populations have diverged genetically to such an extent that they can no longer interbreed, as indicated by the red x.

Speciation—the development of reproductive isolation between populations—is, therefore, typically a by-product of the genetic divergence of separated populations. Because this process requires genetic isolation between the diverging populations and because geography is the easiest way to ensure physical and therefore genetic isolation, many models of speciation focus on geography.

The process usually begins with the creation of **allopatric** (literally, “different place”) populations, which are geographically separated from each other. Clearly, physical separation does not immediately cause reproductive isolation. If a

single population is split in two by a geographic barrier for just a few generations and then individuals from each population are able to interbreed again, they will still be capable of producing fertile offspring. In this case, for speciation to occur, geographic separation is not enough; the process also requires enough time for different mutations to occur, increase in frequency, and eventually become fixed in the two separated populations so that the two populations become reproductively isolated from each other.

There are two ways in which populations may become allopatric. The first is by dispersal, in which

some individuals colonize a distant place, such as an island, far from the main source population. The second is by vicariance, in which a geographic barrier arises within a single population, separating it into two or more isolated populations.

Let's consider each way in more detail. For dispersal, a few individuals from a mainland population, the central population of a species, disperse to a new location remote from the original population. This new population then evolves separately from the original population. The change in location may be an intentional act of dispersal, such as young mammals

migrating away from where they were raised, or it could be an accident brought about by, for example, an unusual storm that blows migrating birds off their normal route. The result is a distant, isolated island population.

“Island” in this case may refer to a true island—such as Hawaii—or may simply refer to a patch of habitat on the mainland that is appropriate for the species but is geographically remote from the mainland population’s habitat area. For a species adapted to life on mountaintops, a new island might be another previously uninhabited mountaintop. For a rainforest tree

species, that new island might be a patch of lowland forest on the far side of a range of mountains that separates it from its mainland forest population.

Evolutionary change may occur rapidly in the island population for two reasons. First, the island population is often small and, as we discussed in Module 43, genetic drift is more pronounced in smaller populations than in larger ones. Second, the environment may differ between the mainland and the island, and the process of natural selection can drive differences between the two populations as they adapt to their different environments. Together,

these two mechanisms cause genetic divergence of the island population from the mainland one, ultimately leading to speciation.

FIGURE 47.7 provides a glimpse of this process in action. Studies of the kingfisher *Tanysiptera galatea* on the island of New Guinea and other nearby islands in the Pacific near Australia show the process under way. There are eight recognized forms of *T. galatea*. Three forms are found on mainland New Guinea where they exist in large populations separated by mountain ranges. Five forms live in small populations on small nearby islands. The mainland forms are still quite similar to one

another, but the island forms are much more distinct, suggesting that genetic divergence is occurring rapidly in the small island populations. If we wait long enough, these different groups of birds will probably diverge into new species.

FIGURE 47.7 Allopatric speciation by dispersal

There are eight forms of kingfishers on New Guinea and the surrounding islands near Australia, indicated by the eight different colors. The three on New Guinea are very similar to one another, but the five on the nearby islands are quite distinct from one another, suggesting that speciation is underway.

Data from Futuyma, D. J. 2009. *Evolution,* 2nd

ed. Sunderland, MA: Sinauer Associates, Fig. 18.7, p. 484.

FIGURE 47.8 shows the best-known example of dispersal, the finches of the Galápagos Islands, made famous by Charles Darwin. We know that the oldest of the Galápagos Islands were formed 4–5 million years ago by volcanic action. Early in the history of the Galápagos, individuals of a small South American finch species arrived there. Conditions on the Galápagos are very different from those on the South American continent, where the mainland population of this ancestral finch lived, so the isolated island population evolved to become distinct

from its mainland ancestor and eventually became a new species.

FIGURE 47.8 Darwin's finches

Today, 18 different species of Darwin's finches are recognized. Here we show the 14 major groups, all descended from a common ancestor from the South American mainland.

Data from: Grant, P. R., and B. R. Grant. 2008. *How and Why Species Multiply*. Princeton, NJ: Princeton University Press, Fig. 2.1, p. 15.

The finches subsequently dispersed among the other islands of the Galápagos, which led to further speciation. Today, there are at least 15 different species of finches on the

Galápagos, as shown in the phylogenetic tree in Figure 47.8. Furthermore, the number of finch species is correlated with the number of islands in the archipelago. As the number of islands increased over time, so did the number of finch species, as shown in the graph in **FIGURE 47.9**. This is a clear indication of the importance of geographic separation (allopatry) in speciation: the availability of islands provided opportunities for populations to become isolated from one another, allowing speciation. The result was the evolution of many species of finches, collectively known today as Darwin's finches.

FIGURE 47.9 Graph of number of

islands and number of species over time

As the number of islands in the Galápagos increased, so did the number of species of finches. This observation supports the idea that geographic separation is a key factor in promoting reproductive isolation, and therefore speciation.

Data from Grant, P. R., and B. R. Grant. 2008. *How and Why Species Multiply*. Princeton, NJ: Princeton University Press, Fig. 2.4, p. 23.

Darwin's finches provide a clear and ongoing example of the evolution of a single population through dispersal. In contrast, vicariance involves a

geographic barrier arising and splitting one population into two or more populations. For example, when sea levels rose at the end of the most recent ice age, new islands formed along coastlines as the low-lying land around them was flooded. The populations on those new islands suddenly found themselves isolated from other populations of their species. Note that the individuals in this case did not disperse to these new islands, as was the case in the Galápagos. Instead, the individuals were already there, and the islands formed around them by the rising sea level. This kind of island formation is called a vicariance event.

Regardless of how the allopatric populations came about—whether through dispersal or vicariance—the outcome is the same: the two separated populations diverge genetically until speciation occurs. However, allopatric speciation by vicariance is often easier to study than allopatric speciation by dispersal because we can date the time at which the populations were separated based on the date when the barrier arose. One such event whose history is well known is the formation of the Isthmus of Panama between Central and South America, described in "Practicing Science 47.1: Can a new geographic barrier cause speciation?" This event took place approximately

3.5 million years ago. In its wake, populations of marine organisms in the western Caribbean and eastern Pacific that had formerly been able to interbreed freely were separated from each other. The result was the formation of many distinct species, with each one's closest relative being on the other side of the isthmus.

Practicing Science 47.1

Can a new geographic barrier cause speciation?

PREP FOR THE AP® EXAM

Background More than 3.5 million years ago, the Isthmus of Panama connecting North and South America was not

completely formed, as shown in the map. An isthmus is a narrow stretch of land connecting two larger areas of land. Several marine corridors remained open, indicated by the black arrows. These corridors allowed interbreeding between marine populations in the Caribbean Sea and the eastern Pacific Ocean. Subsequently, about 3.5 million years ago, the marine corridors were completely closed, separating the Caribbean and eastern Pacific populations and preventing gene flow between them, shown in the map.

Hypothesis In 1993, American marine biologist Nancy Knowlton and her colleagues hypothesized that patterns of speciation would reflect the fact that

direct marine connections between the Pacific and the Caribbean were closed. Specifically, they reasoned that each ancestor species from the time before the formation of the isthmus would have split into two daughter species, one in the Caribbean and the other in the Pacific. They predicted that the closest relative of each current Pacific species would be a Caribbean species, and that the closest relative of each current Caribbean species would be a Pacific species.

Experiment One study focused on 17 species of snapping shrimp in the genus *Alpheus,* a group that is distributed on both sides of the isthmus. The first step was to sequence the same segment of DNA from each species. The next step was to compare those sequences in

order to reconstruct the phylogenetic relationships among species.

Results The phylogenic tree that the researchers created from their data is shown in the figure. It reveals that the closest relative of each species is one from the other side of the isthmus. For example, the closest relative of Pacific 6 is Caribbean 6. These two species share a common ancestor, indicated by the yellow dot, that is more recent than either shares with any other species. This paired pattern of relatedness holds for many of the species studied and results from the geographic separation of the species by vicariance and subsequent speciation.

Conclusion The consistent Pacific–

Caribbean sister species pairings strongly support the hypothesis that the vicariance caused by the formation of the Isthmus of Panama has driven speciation in *Alpheus*. Each Pacific–Caribbean pairing is derived from a single ancestral species whose continuous distribution between the Caribbean and eastern Pacific was disrupted by the formation of the isthmus. Here, we see striking evidence of the role of vicariance in multiple speciation events.

Follow-up Work Speciation is about more than just genetic differences between isolated populations, as shown here. Knowlton and colleagues also tested the different species for reproductive isolation and found that there were high levels of isolation

between Caribbean–Pacific pairs. Because we know that the Isthmus of Panama formed 3.5 million years ago, we know that speciation in these shrimp played out within this timeframe.

AP® PRACTICE QUESTION

a. **Identify** the following:

1. The question being investigated
2. The hypotheses tested
3. The experimental group
4. The control group: against what were the results compared?
5. The independent variable

6. The dependent variable

b. **Explain** the results of the experiment by **identifying** the researchers' claim and **justifying** the claim with the evidence and the reasoning the researchers used (CER).

Sympatric Speciation

Can speciation occur without geographical separation of populations? The answer to this question is "yes," although evolutionary biologists are still exploring how common this phenomenon is. Recall our discussion of Figure 47.6, which shows how separated populations inevitably diverge genetically over time. If a

mutation arises in population A after it has separated from population B, that mutation will be present only in population A. The mutation may eventually become fixed in population A—its frequency will be 100% and all members of the population have it. This can happen either through natural selection, if the mutation is advantageous, or through genetic drift, if it is neutral. Once the mutation is fixed in population A, it represents a genetic difference between populations A and B. Over time, repeated independent fixations of different mutations in the two populations will cause the populations to diverge genetically and become reproductively isolated.

Now imagine that populations A and B are not completely separated, and there is some gene flow between them. The mutation that arose in population A can, in principle, appear in population B as members of the two populations interbreed. Gene flow prevents the genetic divergence of populations. If there is gene flow, a pair of populations may change over time, but they do so together. How, then, can speciation occur if gene flow exists? The term we use to describe populations that are in the same geographic location is **sympatric** (literally, "same place"). So, we can rephrase the question as follows: how can speciation occur sympatrically?

For speciation to occur sympatrically, natural selection must act strongly to counteract the effect of gene flow. Consider two sympatric populations of finch like birds, represented in the graph in **FIGURE 47.10**. One population begins to specialize in feeding on small seeds and the other in feeding on large seeds. If the two populations freely interbreed, no genetic differences between the two occur, and speciation does not take place.

FIGURE 47.10 Sympatric speciation by disruptive selection

Natural selection eliminates individuals in the middle of the spectrum, in this case birds with medium bills, because of

the absence of medium-sized seeds. It favors the extremes, birds with small and large bills, because of the presence of small and large seeds.

Now suppose that the offspring produced by the pairing of a big-seed specialist with a small-seed specialist is an individual best adapted to eat medium seeds, and there are no medium-sized seeds available in the environment. Natural selection acts against the hybrids, which starve to death because there are no medium-sized seeds for them to eat and they are not well adapted to compete with the big- or small-seed specialists. Natural selection, in effect,

eliminates the products of gene flow. So, although gene flow is occurring, it does not affect the divergence of the two populations because the hybrid individuals do not survive to reproduce. As discussed in Module 41, this form of natural selection, which operates against the middle of a spectrum of variation, is called disruptive selection.

It turns out to be difficult to find evidence of sympatric speciation in nature. We might find two very closely related species in the same location and argue that they arose through sympatric speciation. But there is an alternative explanation; one species could have arisen

elsewhere by allopatric speciation and subsequently moved into the environment of the other species.

However, recent studies of plants on an isolated island have provided strong, if not definite, evidence of sympatric speciation. Lord Howe Island is a tiny island off the coast of Australia. Two species of palm tree that are found only on this island are each other's closest relatives. Because the island is so small, there is little chance that the two species could be geographically separated from each other, meaning that the species are and were sympatric. Moreover, because of the distance between Lord Howe Island and Australia or other

islands, it is extremely likely that the palms evolved and speciated from a common ancestor on the island and were not transported there from Australia.

The two palm tree species on Lord Howe Island and other evidence show that sympatric speciation can occur. We must recognize, however, that we do not yet know just how much of all speciation is sympatric and how much is allopatric.

Speciation Rates

Speciation is typically a gradual process. If we try to cross members of two populations that have genetically diverged but not yet diverged far

enough for full reproductive isolation to have arisen, we may find that the populations are partially reproductively isolated. In other words, they are not truly separate species, but the genetic differences between them are extensive enough that the hybrid offspring they produce have reduced fertility or viability compared to offspring produced by crosses between individuals within each population.

Because genetic divergence is typically gradual, we often find allopatric populations that have yet to evolve even partial reproductive isolation but that have accumulated a few population-specific traits. This

genetic distinctness is sometimes recognized by taxonomists, who call each geographic form a subspecies and add a further designation after its species name. For example, Sri Lankan Asian elephants, subspecies *Elephas maximus maximus,* are generally larger and darker than their Indian counterparts, subspecies *Elephas maximus indicus,* both shown in Figure 47.2.

Occasionally, speciation can occur rapidly. Let's return to the example of the Galápagos finches. Consider the finch ancestor immigrants arriving on the Galápagos. Many ecological opportunities were open and available to them. Until the arrival of

the colonizing immigrant birds, there were no birds on the islands to eat the plant seeds, or to eat the insects on the plants, and so on. Suppose that the finch ancestors fed specifically on medium-sized seeds on the South American mainland; that is, they were medium-seed specialists, with bills that were the right size for handling medium-sized seeds. On the mainland, they were constrained to that size of seed because any attempt to eat larger or smaller seeds brought them into conflict with other species—a large-seed specialist and a small-seed specialist—that already used these resources.

When the medium-billed immigrants

first arrived on the Galápagos, however, no such competition would have existed. Therefore, natural selection could have promoted the formation of new species of small- and large-seed specialists from the original medium-seed-eating ancestral stock. Selection would have favored the large and small extremes of the bill-size spectrum because these individuals could take advantage of the abundance of unused resources, consisting of small and large seeds. In addition, some finches would have specialized in other food sources, like insects. In the end, one species of finch gave rise to about 15 species of finch in a relatively short period of time.

The Galápagos finches and their frenzy of speciation illustrate the idea of **adaptive radiation**, a bout of unusually rapid evolutionary diversification in which natural selection accelerates the rates of both speciation and adaptation. Adaptive radiation occurs when an environment offers many ecological opportunities for exploitation.

In some cases, speciation can occur even more rapidly, in a single generation. Typically, cases of such rapid speciation are caused by hybridization between two species in which the offspring are reproductively isolated from both parents. For example, hybridization

in the past between two sunflower species, *Helianthus annuus* and *H. petiolaris* (the ancestor of the cultivated sunflower), has apparently given rise to three new sunflower species, one of which, *H. anomalus,* is shown in **FIGURE 47.11**. *H. petiolaris* and *H. annuus* have probably formed innumerable hybrids in nature, virtually all of them not viable. However, a few hybrids survived to yield these three daughter species. Each of these new species acquired a different mix of parental chromosomes. It is this species-specific chromosome complement that makes all three distinct and reproductively isolated from the parent species and from one another.

FIGURE 47.11 Speciation by hybridization in sunflowers

Helianthus anomalus (bottom) is the product of hybridization between *H. annuus* (top left) and *H. petiolaris* (top right).

In many cases of hybridization, chromosome numbers are different in the offspring compared to the parents. Two diploid parent species with 5 pairs of chromosomes, for a total of 10 chromosomes each, may produce a hybrid offspring with double the number of chromosomes. That is, the hybrid inherits a full paired set of chromosomes from each

parental species for a total of 20. In this case, the hybrid has 4 genomes rather than the diploid number of 2. We call such a double diploid a tetraploid. Tetraploidy is a type of polyploidy, where organisms have more than two sets of chromosomes, as described in Module 37. In general, animals cannot sustain this kind of expansion in chromosome number, but plants often can. As a result, the formation of new species through polyploidy has been relatively common in plants.

Do we ever see rapid speciation without changes in chromosome number? Analysis of Darwin's finches in the Galápagos Islands suggests that

hybridization between closely related species may occasionally result in the evolution of a new species, as shown in **FIGURE 47.12**. Detailed study of a population of finches on one small island, Daphne Major, allowed scientists to identify a hybridization event between a resident *Geospiza fortis* female and an incoming male *G. conirostris* from another island, Española. The offspring of this pairing were able to breed to produce a population that is reproductively isolated from Daphne Major's resident *G. fortis*.

FIGURE 47.12 Speciation by hybridization in Darwin's finches

A new species of Darwin's finch derived

from a mating between members of two closely related finch (*Geospiza*) species.

Data from Sangeet Lamichhaney, modified from Lamichhaney et al. 2018. “Rapid Hybrid Speciation in Darwin’s Finches.” *Science* 359:214–218.

The bill size of the new species is different from those of other finch species, so the new species can specialize on food resources not readily accessed by other species. Remarkably, this new species, informally called Big Bird, evolved over just two generations, so is another great example of evolution in our time, discussed in Module 44. Undoubtedly this was an unusual

event, but, given the vast periods of time over which the evolutionary process unspools, perhaps rare events such as this one play an important role in the generation of new species.

Given the different rates for speciation, from slow to rapid, there are different models to explain change over time. In one extreme, called **gradualism**, species change slowly over time, adapting to environments that are changing slowly. At the other extreme is **punctuated equilibrium**, a model in which there are periods of relatively little change, followed by periods of rapid diversification. In other words, periods of stability, or equilibrium,

are interrupted or punctuated by periods of rapid change in the number of species. Rapid changes often occur when the environment changes suddenly or when species find themselves in novel environments. In both cases, we see evolution occurring in response to environmental change; they differ in the rate and pattern of change of the environment.

"**Visual Synthesis 7.1: Speciation**" summarizes the evolutionary mechanisms that lead to speciation. Speciation is caused by the accumulation of genetic differences between populations. Mutation is therefore a key component of the

process, but so, too, is the fixation process. Recall from Module 42 that fixation occurs when the frequency of a mutation or allele reaches 1, or 100%, meaning that all of the individuals in a population have it. For example, a mutation can be fixed by selection if it is advantageous, or by genetic drift if it is neutral. Multiple evolutionary mechanisms acting over long periods on each population produce the differences that accumulate between diverging populations.

✓ Concept Check

5. **Describe** the difference between allopatric and sympatric speciation.

6. **Describe** the difference between

allopatric speciation by dispersal and allopatric speciation by vicariance.

7. **Describe** why there are so many examples of adaptive radiation on volcanic islands such as the Galápagos.

Module 47 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Using the content of this module, **describe** one type of barrier that might lead to reproductive isolation between populations.

LG 47.1 Species are reproductively isolated from other species.

- The biological species concept (BSC) states that species are groups of actually or potentially interbreeding populations that are reproductively isolated from other such groups. Page 663
- The BSC does not apply to asexual or extinct organisms. Page 664
- Hybridization among closely related species further demonstrates that the BSC is not a comprehensive definition of species. Page 664
- Other species concepts include the morphospecies concept, ecological species concept, and phylogenetic species concept. Page 665
- The BSC is especially useful

because it emphasizes reproductive isolation. Page 666

LG 47.2 Reproductive isolation is caused by barriers to reproduction before or after fertilization.

- Reproductive barriers can be prezygotic, occurring before egg fertilization, or postzygotic, occurring after egg fertilization. Page 666
- Prezygotic isolation may be geographic, ecological, temporal, behavioral, gametic, or mechanical. Page 667
- In postzygotic isolation, mating occurs but genetic incompatibilities prevent the development of viable, fertile

offspring. Page 667

LG 47.3 New species arise by the process of speciation.

- Speciation underlies the diversity of life on Earth. Page 668
- Speciation is typically a by-product of genetic divergence that occurs as a result of the fixation of different mutations in two populations that are not regularly exchanging genes. Page 668
- Most speciation is thought to be allopatric, involving two geographically separated populations. Page 668
- If divergence continues long enough, chance differences will arise that result in reproductive

barriers between the two populations. Page 669

- Geographic separation may be caused by dispersal, resulting in the establishment of a new and distant population, or by vicariance, in which the range of a species is split by a change in the environment. Page 669
- Speciation may be sympatric, meaning that there is no geographic separation between the diverging populations. Page 673
- Speciation is typically gradual, but can also occur rapidly or even instantaneously. Page 674
- Adaptive radiation, in which speciation occurs rapidly to

generate a variety of ecologically diverse forms, is best documented on oceanic islands following the arrival of a single ancestral species. Page 676

Review Questions

1. The biological species concept states that species are reproductively isolated from other species and are actually or potentially

A. interbreeding.
B. cohabitating.
C. naturally selected.
D. physically similar.

2. When you use a field guide to identify a species by its appearance, you are applying the

A. ecological species concept.
B. biological species concept.
C. morphospecies concept.
D. evolutionary species concept.

3. Speciation requires that two populations become

A. geographically separated.
B. reproductively isolated.
C. temporally separated.
D. behaviorally separated.

4. Populations that are geographically separated from one another are called

A. allopatric.
B. sympatric.
C. patric.
D. hybrids.

5. Which is the process by which two populations of the same species living in the same habitat diverge into separate species?

A. Allopatric speciation
B. Sympatric speciation

C. Adaptive radiation
D. Co-speciation

6. It is difficult to apply the biological species concept to bacteria because

A. bacteria are haploid.
B. bacteria reproduce asexually.
C. bacteria lack morphological variation.
D. bacteria are found everywhere.

7. The biological species concept is least useful for

A. identifying plant species.
B. identifying animal species.
C. identifying species represented by fossils.
D. identifying species in marine

environments.

Module 47 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

1. Which is an example of postzygotic isolation?

   A. Members of two species do not recognize each other's courtship displays.
   B. Members of two species

attempt to mate but are physically unable to do so.

C. Members of two species mate but the sperm is unable to enter the egg.

D. Members of two species mate but their offspring are sterile.

2. Which scenario would most likely result in allopatric speciation?

A. A rapid change in the environment imposes new selective pressures on a species.

B. A major environmental event eliminates the dominant species from an ecosystem, allowing previously rare species to flourish.

C. A major geologic event separates a formerly continuous species range into two isolated ranges.
D. A long period of environmental stability promotes gradual evolution in a species.

Use the following information to answer questions 3 and 4.

The caterpillars of the European corn borer (ECB) moth do tremendous damage to cornfields in North America. There are two common types of ECB, both common across the entire species range. As shown in the graph, the univoltine type produces one generation per year

with adult moths emerging in late June and early July. The bivoltine type produces two generations per year with adult moths emerging in early June and early August. The adult moths mate and lay eggs to form the next generation. In the laboratory, univoltine and bivoltine moths are capable of mating and producing viable and fertile offspring.

1. Based on the data provided, which statement most accurately describes this system?

   A. The two moths are different species because the adult moths never encounter each

other and therefore cannot interbreed.

B. The two moths are the same species because they interbreed and produce fertile offspring in the laboratory.

C. The two forms are different species because they are developmentally and morphologically distinct.

D. The two forms are the same species because they reach similar numbers in the natural environment.

2. Chemical insecticides are used to control ECB outbreaks in agricultural settings. Which would be most likely to occur if a mutation conferring resistance to

insecticide appeared in a univoltine individual?

A. Natural selection would increase the frequency of the resistance mutation in univoltine ECB only.
B. Natural selection would increase the frequency of the resistance mutation in bivoltine ECB only.
C. Natural selection would increase the frequency of the resistance mutation in both univoltine and bivoltine ECB.
D. Natural selection would increase the frequency of bivoltine ECB in the population.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

The island of Plaza Sur is home to two groups of iguanas. The marine iguana (*Amblyrhynchus cristatus*) has a solid gray or black color and lives near the water's edge. The marine iguana is a strong swimmer whose food source is underwater seaweed. The land iguana (*Conolophus subcristatus*) has a brown or gray back and yellow or orange legs and underside. Land iguanas remain on land and primarily eat

cactus. Occasionally marine iguanas and land iguanas mate. The offspring from these matings have dark bodies with yellow stripes, are capable of swimming, and eat both cactus and seaweed. The offspring from matings between marine iguanas and land iguanas are sterile.

a. Based on the data provided, should marine iguanas and land iguanas be considered separate species? **Justify** your claim with reasoning.
b. Imagine that a new mutation occurs in a marine iguana. The new mutation causes the marine iguana to become more attracted to the mating displays of other marine iguanas and less attracted

to the mating displays of land iguanas. **Predict** whether this mutation will be advantageous, disadvantageous, or selectively neutral. **Support your claim** with reasoning.

c. Imagine that a new mutation occurs in a land iguana. The new mutation causes the land iguana to become more attracted to the mating displays of marine iguanas. **Predict** whether this mutation will be advantageous, disadvantageous, or selectively neutral. **Support your claim** with reasoning.

VISUAL SYNTHESIS 7.1 SPECIATION

Speciation is the process by which one species becomes two species. In this example, a single population of fish, the parent population, is physically separated into two populations, daughter populations A and B, by a geographic barrier. Different mutations occur and then are fixed in the two daughter populations by processes such as genetic drift and natural selection. Over time, the two populations become so genetically different from each other

that they can no longer interbreed with each other and produce fertile offspring. At this point, speciation is complete.

Module 48

Extinction

LEARNING GOALS

- **LG 48.1 Species are lost by the process of extinction.**
- **LG 48.2 Five mass extinctions have altered the course of evolution.**
- **LG 48.3 Extinction opens up habitats that can be filled by other species.**
- **LG 48.4 Humans are changing the environment, leading to the loss of many species.**

In the last module, we discussed speciation, the process by which one species becomes two species. On a phylogenetic tree, we represent speciation as a branch point, where one line splits into two. This process of branching, played out over time, has led to the remarkable diversity of species we see today. Currently, Earth is home to an estimated 10 million species, all descended from a single common ancestor. We have named and described only a small fraction of these species, which differ in many ways and are adapted to a multitude of habitats across the planet.

At the same time, scientists estimate that 99% of species that have ever

lived no longer exist. So, just as speciation is common, so is **extinction**, the loss of a group of organisms. Extinction is the flip side of speciation: whereas speciation is the engine of biodiversity, extinction represents the loss of species and biodiversity. Both speciation and extinction have occurred repeatedly over the history of life on Earth. At any point of time, even today, the number of species present reflects the rate of both speciation and extinction.

In this module, we will focus on the process of extinction—what it is, when it has occurred in the history of life, the open habitats it often leaves

in its wake, and the staggering rates of extinction we are seeing today as a result of human activity.

FOCUS ON THE BIG IDEAS

48.1 Species are lost by the

process of extinction

Charles Darwin wrote, “When a species has once disappeared from the face of the Earth … the same identical form never reappears.” He wasn’t being sentimental or nostalgic when he wrote this sentence. Instead, he was describing the process of extinction in clear terms. Every species is the result of its unique history. Therefore, when a species goes extinct, that group of organisms is lost forever. It cannot be recreated because it is impossible to go back in time and replay the path it took from its beginning. The same can be said about any individual, including you. Species and individuals exist at a

specific time and result from their own unique genetic and evolutionary histories.

On a phylogenetic tree, we can represent an extinction event as a branch that simply stops before making it to the present day. **FIGURE 48.1** shows a phylogenetic tree of birds and their extinct relatives, the dinosaurs. Note that many branches stop before making it to the present day. These are species that have gone extinct.

FIGURE 48.1 Birds, crocodiles, and their extinct relatives

This phylogenetic tree shows the evolutionary relationships of crocodiles, extinct dinosaurs, and living birds.

Notice that the branches that lead to different species of dinosaurs do not extend to the present. These are extinct groups of dinosaurs.

Data from Zimmer, C. 2009. *The Tangled Bank.* Greenwood Village, CO: Roberts and Company.

Extinction is exceedingly common in the history of life on Earth. Some species go extinct as a result of environmental change because they are unable to adapt quickly enough to survive. Some go extinct as a result of predation, hunting, or overharvesting. And some species simply change and adapt, so that, over time, the descendants of the

original species are so different from the original that we say that the original species has gone extinct.

Extinction occurs when the last individual of a species dies. Most extinctions go unnoticed and unrecorded. One exception was the death of Martha, the very last passenger pigeon (*Ectopistes migratorius*), who died in the Cincinnati Zoo on September 1, 1914. She is pictured in **FIGURE 48.2**. Although extinction occurs when the last surviving member of a species dies, species are often doomed to extinction well before then; once their populations fall to very low levels, the species is often not able to

recover.

FIGURE 48.2 Martha, the last passenger pigeon

This is a photograph of Martha, who lived in the Cincinnati Zoo and was the last surviving member of her species. She died on September 1, 1914. The 100th anniversary of the extinction of her entire species was marked by many exhibits and articles.

Extinction helps us to understand a key feature of any ecosystem, biodiversity. Biodiversity, or biological diversity, often refers to the number of species, but more broadly it includes the variety of genetic sequences among individuals of a species; the different cell types,

metabolisms, and life histories among species; or even groups of organisms in different habitats around the world. We can also consider biodiversity for a particular place, such as a single tropical rainforest, or the entire planet.

A common way to measure biodiversity is to count the number of species present in a particular area. We don't know how many species exist on our planet, although the number certainly runs into the millions and may exceed 10 million. Whether local or global, patterns of biodiversity reflect the processes of both speciation and extinction. The balance of the two processes

determines the total number of species. That is, the number of species at any point in time is the result of rates of speciation and extinction that have occurred in the past. So, a group of organisms, like a genus with many species, might have experienced high rates of speciation, low rates of extinction, or both.

When the number of species increases over time, we can infer that that rate of speciation exceeds the rate of extinction. When the number of species decreases over time, we can infer that the rate of extinction exceeds the rate of speciation. The two processes together help us to understand levels of biodiversity.

✓ Concept Check

1. **Describe** extinction.

2. **Describe** how to represent extinction on a phylogenetic tree.

3. **Identify** the two processes that determine the total number of species, which is one measure of biodiversity.

48.2 Five mass extinctions have altered the course of evolution

Beginning in the 1970s, American paleontologist Jack Sepkoski scoured the paleontological literature, recording the first and last appearances in the fossil record for every genus of marine animal he could find. The results of this monumental effort are shown in **FIGURE 48.3**. Sepkoski's diagram shows that animal diversity has increased over the past 500 million years. In fact, the biological diversity of animals in today's oceans may well be higher than it has ever been in the past. At the same time, it is clear that animal evolution is not simply a

history of continual accumulation. Instead, it is punctuated by periods of extinction.

FIGURE 48.3 Mass extinctions

Five times in the past 500 million years, Earth experienced a sudden and large loss of groups of organisms, called a mass extinction. Each significant drop in the graph represents a mass extinction, indicated by an arrow. Time periods are shown across the top.

Data from *Sepkoski's Online Genus Database*. http://strata.geology.wisc.edu/jack/

Five times during the past 500 million years or so, animal diversity in the oceans has dropped both rapidly and

substantially; waves of extinctions have also occurred on land. These are known as mass extinctions, which are periods of rapid and substantial loss of biodiversity. These events eliminated ecologically important taxa, that is, those that either played a key role in the functioning of an ecosystem or were dominant in terms of numbers of organisms. As a result, these extinctions provided evolutionary opportunities for the survivors.

The best-known mass extinction occurred 66 million years ago, at the end of the Cretaceous Period, indicated by the rightmost arrow in Figure 48.3. On land, dinosaurs

disappeared abruptly, following approximately 150 million years of dominance in terrestrial ecosystems. In the oceans, mollusks called ammonites, which had long been abundant predators, became extinct, and most skeleton-forming microorganisms in the oceans disappeared as well. A large body of geologic evidence supports the hypothesis that this biological catastrophe was caused by the impact of a giant meteorite, as discussed in detail in "Practicing Science 48.1: What caused the extinction of the dinosaurs?"

Practicing Science 48.1

What caused the extinction of the dinosaurs?

PREP FOR THE AP® EXAM

Background Dinosaurs dominated Earth for approximately 150 million years, but became extinct approximately 66 million years ago.

Observation Rock layers accumulate over time, with older layers deeper than younger layers. These layers can be dated using radioactive decay of isotopes, as described in Module 44. Iridium, a type of metal, was found in layers of rock that correspond to the time of the dinosaur extinction. Iridium does not originate on Earth, but is common in space, particularly in meteorites. The iridium layer can be

seen in the following photograph as the white band. (The knife is included for size comparison.) The graph next to the photo shows the peak of iridium in rock layers dated to the end of the Cretaceous Period.

Hypothesis Geologist Walter Alvarez and his colleagues hypothesized that a large meteorite struck Earth. The meteorite was so large and hit Earth with such force that it devastated the area of impact, and also sent soot and other debris into the atmosphere, reducing sunlight. Lack of sunlight disrupted plant communities, which in turn had a domino-like effect on other organisms. Whole communities and ecosystems on land and in the sea were

devastated, which led to the extinction of the dinosaurs and many other species.

Predictions A hypothesis makes predictions that can be tested by observation and experiments. To support the hypothesis, independent evidence of a meteor impact should be found in rock layers corresponding to the time of the extinction and be rare or absent in older and younger layers.

Further Observations A form of quartz called shocked quartz was also found in layers that correspond to the time of the extinction. Shocked quartz, shown in the following photo only forms at very high temperature and pressure, which is consistent with a meteorite impact. In addition, a large crater of the right age

was found off the coast of present-day Mexico, as shown on the map and in the following photo.

Conclusion A giant meteor struck Earth 66 million years ago, causing the extinction of many species, including the dinosaurs.

Follow-up Work Researchers have documented other mass extinctions, but the event that eliminated the dinosaurs appears to be the only one associated with a meteorite impact. Researchers are also studying other factors that contributed to the mass extinction event, such as massive volcanic activity in what is now India and a long period of global climate change both before and after the meteorite impact.

Alvarez, W. 1998. *T. rex and the Crater of Doom.* New York: Vintage Press.

AP® PRACTICE QUESTION

Identify the following:

1. The question being investigated by the experimenters
2. The hypothesis
3. The evidence that supports a meteor striking Earth at approximately the same time that the dinosaurs went extinct
4. The conclusion

Before dinosaurs ever walked on Earth, there were at least four other mass extinction events. The largest of all of these occurred 252 million years ago, at the end of the Permian Period,

when environmental catastrophe eliminated half of all groups of organisms called families in the oceans and approximately 80% of all genera. Estimates of marine species losses run as high as 90%. This mass extinction was so extreme that it is sometimes called the Great Dying.

Geologists have hypothesized that this large mass extinction occurred in the aftermath of massive volcanic eruptions. At the end of the Permian Period about 250 million years ago, most continents were gathered into the supercontinent Pangaea, shown in **FIGURE 48.4**, and a huge ocean covered more than half of Earth. Levels of oxygen in the deep waters of

this ocean were low because of sluggish ocean circulation and warm ocean temperatures.

FIGURE 48.4 The supercontinent Pangaea

Pangaea is a supercontinent that formed around the time of Permian mass extinction 252 million years ago.

Then a massive outpouring of ash and lava—a million times larger than any volcanic eruption experienced by humans—erupted across what is now Siberia in Russia. Enormous emissions of carbon dioxide and methane from the volcanoes caused global warming, so even less oxygen

reached the deep oceans. As some of the increased carbon dioxide in the atmosphere was absorbed by the oceans, the pH of the seawater decreased. Because a decrease in pH corresponds to an increase in acidity, this phenomenon is known as ocean acidification. Ocean acidification is harmful to marine life, including corals and algae that use calcium carbonate to make their skeletons.

The three-way insult of lack of oxygen, global warming, and ocean acidification caused the extinction of many species in the seas and on land. Seascapes that had been dominated for 200 million years by corals and shelled invertebrates called

brachiopods disappeared. On land, roughly a third of large animals went extinct and most of the trees disappeared.

As both the Cretaceous and Permian events illustrate, extinction rates can be extremely rapid during times of global ecological stress and disruption. Mass extinction events also teach us the important lesson that current levels of biodiversity—both in terms of number of species and what species are present—reflect the interplay through time of evolution, natural selection, and speciation, as well as rare massive perturbations to ecosystems. The fossil record provides a silent witness

to our planet's long and complex evolutionary history.

✓ Concept Check

4. **Identify** the difference between extinction and mass extinction.

5. **Explain** what caused the mass extinction event that eliminated the dinosaurs.

6. **Describe** what the five mass extinctions had in common.

48.3 Extinction opens up habitats that can be filled by other species

In Module 47, we discussed periods of rapid diversification that are commonly seen on islands where there is little or no competition or predation. These bouts of speciation are called adaptive radiation and result from the large number of open habitats that often exist on islands before the arrival of colonists.

What happens on islands is a microcosm of what occurs following a mass extinction. A mass extinction

eliminates many dominant species, opening habitats that were formerly occupied. So, for the survivors, mass extinctions provide ecological opportunities on a grand scale. As ecosystems recover from a mass extinction, they come to be dominated by new groups descended from survivors of the extinction. In other words, periods of extinction of some groups of organisms are often followed by periods of adaptive radiation of other groups of organisms.

For example, by eliminating dinosaurs and much of the biological diversity that had built up over millions of years on land, the mass

extinction at the end of the Cretaceous Period had the effect of generating new evolutionary possibilities for those animals that survived the event, including mammals. During the Mesozoic Era, dinosaurs were dominant both in terms of numbers and importance in land and ocean ecosystems. As a result, this time period in Earth history is sometimes called the Age of Dinosaurs.

Mammals were present during this period as well but were relatively small and not ecologically dominant. The first fossils that clearly show evidence of hair, a key mammalian trait, appeared approximately 210

million years ago, during the Triassic Period. The earliest mammals, the monotremes, lay eggs like birds. Monotremes still living today include the platypus and spiny anteater. The first mammals that gave birth to live young appeared in the Jurassic Period, about 160 million years ago. These animals gave rise to marsupial and placental mammals. The young of marsupial mammals are born at an early stage of development and today include kangaroos, koalas, and opossums. The placental mammals are named for an organ called the placenta, which provides nutrition for the embryo and enables offspring to be larger and more independent when born. Placental mammals

include carnivores, such as cats, dogs, and weasels; primates, including monkeys, apes, and humans; and hooved mammals, which include cattle, pigs, and deer.

Although mammals evolved and diversified during the Age of Dinosaurs, their numbers and ecological importance did not increase until after the end-Cretaceous extinction. In other words, the extinction of the dinosaurs provided many open ecological opportunities for mammals, so they were well poised to become ecologically dominant in the next time period, the Cenozoic Era, which is sometimes called the Age of

Mammals.

Similarly, following the Great Dying at the end of the Permian Period, new groups took the place of old ones. Bivalve and gastropod mollusks diversified in the absence of their former competitors; new groups of arthropods radiated, including the ancestors of the crabs and shrimps we see today. Surviving sea anemones evolved a new ability to make skeletons of calcium carbonate, resulting in the corals that build reefs. In short, this mass extinction reset the course of evolution, much as it did at the end of the Cretaceous Period. So, when you stroll through a zoo or snorkel above a coral reef, you are not

simply seeing the products of natural selection played out over Earth history. Instead, you are encountering the descendants of Earth's biological survivors.

✓ Concept Check

7. **Identify** the process by which speciation happens relatively quickly following a mass extinction or in any situation where there are lots of available habitats.

8. Dinosaurs once dominated many ecosystems. **Identify** the group of organisms that became dominant after the dinosaurs went extinct.

48.4 Humans are changing the environment, leading to the loss of many species

As we have seen, high rates of extinction often occur during periods of ecological stress. While species are often able to adapt to a slowly changing environment, sudden changes pose a particular challenge. In this case, there may be no variants present that can survive and

reproduce in the new environment. Therefore, if the environment changes too quickly and species are unable to adapt, they may go extinct. We saw examples of severe ecological stress in the aftermath of a meteorite striking Earth at the end of the Cretaceous Period and following massive volcanism at the end of the Permian Period. Today, humans are changing the environment on a global scale and in a relatively short amount of time, especially when we keep in mind the long arc of the history of life on this planet. Our actions are affecting, directly or indirectly, other species. By changing the environment, we are changing the selective landscape in which

organisms live and evolve.

Our effect on the environment is partly the result of our sheer numbers. More humans are alive today than ever before, and our numbers are climbing rapidly. A world that had approximately 500 million inhabitants in the year 1500 now supports more than 7.8 billion people. By the time you retire, our numbers will probably exceed 9 billion. You can see this remarkable growth of the human population in **FIGURE 48.5**. Although our numbers have grown exponentially, the population growth rate is slowing down and our numbers are expected to level off around 2100.

FIGURE 48.5 Growth of the human population over time

The human population has grown exponentially over time. Currently, humans number over 7.8 billion people.

As our numbers have grown, we have seen remarkable successes, particularly in the areas of public health and medicine. We have built great cities and created art, literature, and culture. We have developed sophisticated technologies that allow for rapid transportation, communication, and computing. At the same time, we use increasing amounts of energy, take up more and

more space, and consume ever more food. Along the way, we are also destroying habitats, overharvesting many species, polluting ecosystems, introducing invasive species, and changing the composition of the atmosphere and oceans by burning fossil fuels. Increasingly, scientists refer to the modern time as the Anthropocene, from the Greek *anthropos,* meaning "human." This name emphasizes the dominant impact of humans on the present-day Earth.

As our population has increased, some species have expanded along with us. Some of these species are shown in **FIGURE 48.6**. Our pursuit of

agriculture has sharply increased the abundance and distribution of animals and plants that we cultivate, such as corn, wheat, sheep, and cows. At the same time, we have inadvertently helped other species to expand—the crowded and not always clean environments of cities provide excellent habitats for cockroaches and rats.

FIGURE 48.6 Species that have benefited from human activity

Species that have benefited from human activity include (a) corn, (b) rats, and (c) cockroaches.

Other species are in decline, their populations reduced by hunting and fishing, changes in land use, and

other human activities. In fact, the numbers of species we are losing and the rapidity of this loss have forced scientists to consider whether we are in the midst of a sixth mass extinction, reminiscent in size and scale of the other five mass extinctions. However, this one differs from the other five in at least two important ways. First, it is occurring much more rapidly than the others. Second, current threats come not from meteorites or massive volcanism as in past mass extinctions, but rather from humans. This also means there is reason to hope, as we can do something about it if we choose to.

Several species that are endangered or extinct as a result of human activities are shown in **FIGURE 48.7**. At one time, large flightless birds called dodos (*Raphus cucullatus*) on the Indian Ocean island of Mauritius were plentiful. Within a century of Europeans arriving on the island, the dodo was extinct. Other species such as the Bali tiger (*Panthera tigris balica*) have gone extinct in recent decades. Still others are imperiled by human activities. Victimized by habitat destruction and poaching, the last surviving male of the northern white rhinoceros (*Ceratotherium simum cottoni*) died in 2018.

FIGURE 48.7 Species that are extinct as a result of human activity

Through hunting, habitat destruction, and other activities, humans have caused many species to go extinct, including (a) the dodo, (b) the Bali tiger, and (c) the northern white rhinoceros.

A 2016 census of population size for more than 3700 species of mammals, birds, fishes, and amphibians found that the total number of vertebrate animals in nature has declined by 60% over the past 50 years, prompting concern about mass extinction comparable to the mass extinctions of the past. Furthermore, as shown in **FIGURE 48.8** many species face the threat of extinction. Among mammals, for example, about a quarter of all species are vulnerable,

endangered, or critically endangered, meaning that they are unlikely to survive without human intervention.

FIGURE 48.8 Biodiversity at risk

Many mammal, bird, amphibian, fish, and coral species are at risk of extinction. These have been classified as vulnerable (likely to become endangered in the absence of intervention), endangered (likely to become extinct in the absence of intervention), or critically endangered (very high risk of extinction).

Data from IUCN Red List of Threatened Species.

The reasons for loss of species are

complex and various. Some are simply overhunted, prized for their hides or tusks or as sources of food. Some, like the dodo, have evolved in the absence of predators and so are vulnerable to human hunting and introduced species. Still others, like amphibians, are affected by multiple factors. Amphibian habitat is being destroyed in many parts of the world, especially old-growth forests that provide damp, food-rich environments in abundance. Amphibians also take in gases through their skin, making them vulnerable to pesticides and other toxins. Recently, infection has also been implicated in amphibian decline. The fungus *Batrachochytrium*

dendrobatidis (*Bd*) infects the skin of frogs and impairs many of the skin's functions.

The renowned biologist E. O. Wilson has estimated that Earth is losing 0.25% of its species annually—that is, 5000 to 25,000 species per year—depending on how many species actually exist. Even where ecosystems remain physically intact, pollution can erode populations. For example, recent studies in Europe show that levels of certain pesticides in soil and water accurately predict patterns of population decline in bees and birds.

Without question, there will be fewer species when the twenty-first century

ends than when it began. Lost species mean lost opportunities for the discovery of novel compounds for medical research. Diminished biodiversity may make ecological communities less productive and less resilient to fires, hurricanes, or other environmental events. There is a pressing need to feed the world, but there are also many good reasons to conserve the biodiversity that has evolved over 4 billion years. Balancing these two imperatives will entail creative approaches to both science and policy, including thoughtful ways of using land that serve both people and conservation.

In the words of the distinguished

biologist Paul Ehrlich, “The fate of biological diversity for the next 10 million years will almost certainly be determined during the next 50–100 years by the activities of a single species.” In this way, there is reason to be optimistic, as we have the unique ability to make choices that will ensure levels of biodiversity for a healthy planet.

PREP FOR THE AP® EXAM

When answering questions about extinction or changing environments, remember to consider the role of human activity.

✓ Concept Check

9. **Describe** three ways in which humans are causing biodiversity loss.

10. **Identify** one species that has gone extinct as a result of human activities.

Module 48 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Choose one extinct species discussed in the module and **describe** the series of environmental changes that led to the extinction event.

LG 48.1 Species are lost by the process of extinction.

- Extinction is the loss of a group of organisms, such as a species. Page 682
- Extinction is represented on a phylogenetic tree by a branch that does not extend to the present. Page 682
- Levels of biodiversity are determined by rates of speciation and rates of extinction. Page 684

LG 48.2 Five mass extinctions have altered the course of evolution.

- This history of life on Earth is characterized by five mass extinctions, large and rapid losses of biodiversity. Page 684
- Mass extinctions have changed the course of evolution by

eliminating some groups and providing opportunities for other groups to diversify. Page 684

- A meteorite struck Earth 66 million years ago, leading to environmental havoc and extinction of the dinosaurs, among other organisms. Page 685
- The largest documented mass extinction in the history of Earth occurred at the end of the Permian Period 252 million years ago. Page 686

LG 48.3 Extinction opens up habitats that can be filled by other species.

- Mass extinctions are often followed by adaptive radiation among the survivors due to the

availability of many open habitats. Page 686

- When the dinosaurs went extinct at the end of the Cretaceous Period, habitats were opened up that were filled in part by mammals. Page 687

LG 48.4 Humans are changing the environment, leading to the loss of many species.

- Humans have altered the landscape in dramatic ways, leading to the expansion of some species, such as corn and wheat, and the decrease and extinction of others, such as the dodo and Bali tiger. Page 688
- Some scientists believe that we

are currently experiencing extinction at a level and rate similar to other mass extinctions in Earth's history. Page 688

- Current biodiversity loss is due to human activities, such as habitat destruction, pollution, overharvesting, invasive species, and climate change. Page 690

Key Term

Extinction

Review Questions

1. Dinosaurs went extinct at the end of which period?

A. Cretaceous
B. Devonian
C. Permian

D. Triassic

2. During the Permian extinction, what percentage of species in the ocean disappeared?

A. 90%
B. 25%
C. 50%
D. 75%

3. The largest documented mass extinction on Earth occurred

A. 2.5 million years ago.
B. 25 million years ago.
C. 65 million years ago.
D. 252 million years ago.

4. One cause of biodiversity loss is the introduction of non-native species, or

A. convergent species.
B. invasive species.
C. natural species.
D. endemic species.

5. Which statement regarding biodiversity is true?

A. Earth is gaining 2.5% of its species annually.
B. There will be fewer species at the end of the twenty-first century than there are now.
C. Loss of biodiversity may result in more productive and resilient communities.
D. Habitat degradation is not a threat to biodiversity.

6. If the rate of extinction exceeds the

rate of speciation, which will occur?

A. The number of species will increase.
B. The number of species will decrease.
C. The number of species will stay the same.
D. The number of species will fluctuate up and down.

Module 48 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions

1–4.

1. Which of the following is a common cause of mass extinction?

   A. Adaptive radiation by previously rare species leads to increased competition and extinction.
   B. Gradual change in the environment leads to extinction of species that are unable to adapt.
   C. Rapid environmental change causes ecosystems around the world to collapse.
   D. Global populations become too large and require more environmental resources than

are available.

2. The number of species in an environment is frequently used as a measure of biodiversity. A scientist studying ferns in the fossil record over a defined geological period estimated that there were approximately 335 species at the beginning of the period. The scientist estimated that 42 of these species went extinct before the end of the period. The scientist also observed 15 speciation events where a single ancestral species gave rise to two descendant species. What is the best estimate of the number of fern species present at the end of the

geological period?

A. 293
B. 308
C. 323
D. 392

3. Jack Sepkoski was a scientist who used the fossil record from marine environments to document five mass extinctions over the past 500 million years. Which of the following is the most likely reason Sepkoski focused his research on marine animals?

A. Fossils are more likely to form in marine environments than in terrestrial environments.

B. The biodiversity in terrestrial environments is too low for identification of mass extinctions.
C. Terrestrial organisms do not experience mass extinctions.
D. Marine environments are more variable than terrestrial environments.

4. Approximately 66 million years ago, a massive meteor impacted Earth, resulting in the extinction of most dinosaurs and an adaptive radiation of mammals. Which statement most accurately describes this event and its consequences?

A. The meteor impact changed

the temperature of Earth, which gave mammals a competitive advantage over dinosaurs.

B. Plant life on Earth changed dramatically as a result of the meteor impact, generating ecosystems that could support mammals but not dinosaurs.

C. The meteor impact changed the chemical composition of Earth's atmosphere, and the new atmosphere was toxic to dinosaurs but not mammals.

D. The meteor impacted caused a major loss of dinosaur biodiversity, which created open ecological habitats that mammals exploited.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

White-tailed deer are currently extremely common in the eastern United States, but their populations have historically varied in size. The figure shows the number of white-tailed deer in Missouri from 1600 to 2020. Four important changes in human activity are indicated on the graph.

Population size of white-tailed deer in

Missouri

a. **Identify** which of the four human factors had the greatest impact on the white-tailed deer population in Missouri.
b. Wolves were hunted to extinction in Missouri between 1800 and 1950. Based on the data provided, and assuming all other factors remain unchanged after 2022, **predict** the effect that re-introducing wolves into Missouri would have on the white-tailed deer population.
c. A scientist claimed that conversion of forest to farmland creates improved habitat for

white-tailed deer. Use the data provided to **support or refute** the scientist's claim.

Module 49

Variation in Populations

LEARNING GOALS

- **LG 49.1 Populations with low levels of genetic variation are at risk of extinction.**
- **LG 49.2 Populations with high levels of genetic variation are often resilient to environmental change.**
- **LG 49.3 Variants that are well adapted to one environment may not be well adapted to another environment.**

In the last module, we discussed the process of extinction, in which a group of organisms is lost. Extinction occurs when the last member of a group, such as a species, dies. However, well before this occurs, a species that is reduced in numbers is at risk of further decline and perhaps extinction. Small populations are at greater risk of decline and extinction because they often contain very little genetic variation. Populations with little genetic variation have a limited ability to adapt to a changing environment. In contrast, populations with considerable genetic variation tend to be resilient and can often adapt to a changing environment.

Genetic variation is fundamental to the ability of a species to adapt because of the role it plays in the evolutionary process. We have seen that genetic variation is the raw material on which evolution acts. It's the starting place for change over time. In fact, variation among members of a species is Darwin's first postulate, as we discussed in Module 41. If there is no variation, then individuals don't differ in fitness and natural selection can't operate. Without variation, there would be no evolution. And if a species can't change and adapt, it is vulnerable to changing environmental conditions.

The relationship between genetic

variation and the ability to adapt also affects the outcome of conservation efforts. Successful conservation programs do not focus only on saving individual members of a species. A sanctuary or zoo with few individuals of a particular species is often not enough to sustain that species over time. Rather, where there are enough individuals to have a genetically diverse and therefore robust population, conservation of habitat is more effective.

In this module, we will discuss what happens to populations with low levels of genetic variation and those with high levels of genetic variation. We will also consider what happens to

a population that is well adapted to a particular environment when the environment changes.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

49.1 Populations with low levels of genetic variation are at risk of extinction

When we think about natural selection, we often focus on the

variants that are best suited to a particular environment. These are the individuals that survive and reproduce, so that, over time, a population of individuals becomes exquisitely adapted to a particular environment.

However, it's important to realize that an environment is not fixed. Instead, it changes all of the time. The environment does not just include factors such as the weather, soil, and other physical aspects of a particular area, collectively called abiotic factors. The environment also includes all the organisms in the area, called biotic factors. These organisms are subject to natural selection and

other evolutionary mechanisms, and often change over time. Therefore, it's best to think of many environments as constantly in flux and changing. Sometimes, environmental change can be major, such as in the aftermath of a meteorite striking Earth, or it can be more subtle, such as changes in rainfall patterns or the numbers of predators. Either way, the environment in which organisms live is constantly changing.

Populations that harbor considerable genetic variation have many different variants available. Some of these may be well adapted to the current environment, and therefore have high fitness, and others less so, and

therefore have low fitness. But those that are less well adapted may be better adapted as the environment shifts. Conversely, those populations with little or no genetic variation are vulnerable to environmental change.

Let's take the example of crops, which are bred in such a way that they often have little genetic variation. We eat surprisingly few of the more than 400,000 species of plants on Earth today. Most of the plants we eat come from species that are grown in cultivation, and many of these cultivated species have, as a consequence of artificial selection, lost the ability to survive and reproduce on their own. Of the

approximately 200 such cultivated species, 12 account for more than 80% of human caloric intake. Just three—corn, wheat, and rice—make up more than two-thirds of the food we eat.

Crop breeders select for varieties that grow well under cultivation and are uniform so are easy to harvest. However, one consequence of selective breeding of crop species is low genetic diversity. Because pathogens and pests are always evolving, low genetic diversity of crop species creates substantial risks. For example, before 1970, the fungal pathogen *Bipolaris maydis* destroyed less than 1% of the U.S. corn crop

annually. In 1970, however, it destroyed more than 15% of the corn crop in a single year. The severity of the epidemic was due to the genetic uniformity of the corn varieties planted at that time. In natural plant populations, genetic variation for pathogen resistance makes it highly unlikely that a newly evolved pathogen strain will be able to infect every plant.

Bananas (*Musa acuminata*) are similarly vulnerable. You may have noticed that while your grocery store or supermarket has several types of apples for sale, there is usually only one type of banana. In fact, it's possible that every banana you have

ever eaten has been the same variety. Now the popular yellow fruit may be in trouble.

Years ago, the Western world favored a banana variety known as the Gros Michel. In the first part of the twentieth century, a devastating fungal infection called Panama disease wiped out Gros Michel plantations around the world. In the 1950s, banana growers turned instead to the Cavendish, a variety that displayed some natural resistance to Panama disease. Half a century later, the Cavendish banana, shown in **FIGURE 49.1**, remains the top-selling banana in supermarkets in North America and beyond.

FIGURE 49.1 Cavendish bananas

Cavendish bananas are a cultivated crop and the typical bananas that you find in a supermarket. They are in danger because of a lack of genetic variation, which is common among cultivated crops.

Yet the reign of the Cavendish may be coming to an end. For years, banana growers have battled black sigatoka, a fungal infection that can cause losses of 50% or more of the banana yield in infected regions. Making matters worse, Panama disease is once again posing a threat. A strain of the disease has emerged against which the Cavendish plants have no resistance. The disease has spread across Asia

and Australia, and experts fear it's only a matter of time before it reaches prime banana-growing regions in Latin America.

For those who enjoy bananas sliced into their breakfast cereal, the loss of bananas would be disappointing. For the millions of people in tropical countries who depend on bananas and related plantains for daily sustenance, the destruction of those crops would be much more serious.

Cultivated bananas are vulnerable to infection in a way that wild bananas are not. The bananas that we eat are sterile; they do not produce seeds. This means they must be propagated

vegetatively, a form of asexual reproduction, by replanting cuttings taken from parent plants. As a result, banana plantations contain virtually no genetic diversity. As Panama disease and black sigatoka are showing, that lack of diversity can have disastrous effects.

Another fungus is threatening global wheat production. Wheat, shown in **FIGURE 49.2**, is a staple crop. Throughout much of human history, wheat and other crops have been vulnerable to infection by the fungus *Puccinia graminis*. *P. graminis* first infects wheat leaves, and then extends within the plant's tissues to fuel its own growth. Rust-colored

pustules, shown in **FIGURE 49.3**, erupt along the stem, giving the infection the name stem rust. These pustules release a large number of spores, after which the plant withers and dies. Crop losses from *P. graminis* can be devastating.

FIGURE 49.2 Wheat, a vulnerable staple

Wheat crops harbor little genetic variation and are therefore susceptible to pathogens, such as fungal wheat rust.

FIGURE 49.3 Fungal wheat rust

The rust coloration on the stems of these wheat plants is the result of infection by a fungus, a major threat to the world's wheat crops.

During World War II, the plant biologist Norman Borlaug traveled to Mexico to help combat crop losses due to rust. Borlaug was eventually able to breed resistant wheat varieties. Much of the resistance shown by his varieties could be attributed to variation in a small number of genes. Wheat rusts were apparently vanquished by Borlaug's work.

However, in 2010, a new strain of wheat rust fungus emerged in the Middle East. In its first year, the disease wiped out as much as half of Syria's wheat crop. It has since spread to other countries in the region. Meanwhile, crop scientists have

warned that Ug99, a particularly damaging strain of *P. graminis*, could devastate global wheat crops. This strain first appeared in the east African country of Uganda, for which it is named.

Like corn farms and banana plantations, most modern wheat farms consist largely of monocultures, single crop species grown over a large area. In a given field of wheat, the plants are often genetically similar to one another. Growing only a single crop at a time makes it much easier to mechanize planting and harvesting. Unfortunately, it also means that a pathogen that can overcome a plant's

natural defenses has the potential to wipe out an entire field.

At the time that Ug99 was discovered, it was capable of defeating all known resistance genes in wheat. These genes provide protection against rusts. In the absence of variation in these and other genes, wheat is susceptible to fungal infection. Given that wheat accounts for 20% of daily global calorie consumption by humans and that 90% of cultivated wheat has little or no resistance to Ug99, the appearance of this resistant fungus is cause for major concern.

The map in **FIGURE 49.4** shows areas where Ug99 is currently found. It is

currently devastating wheat production in Kenya and has been found in Yemen, Iran, South Africa, and Egypt. As of 2019, it was present in 13 countries. In addition, Ug99 shows every sign of continuing to spread. The spread of Ug99 is not surprising given that a single hectare of infected wheat produces upward of 1 billion spores. As you read this, Ug99 is poised to reach the major wheat-growing regions of Turkey and South Asia. Even more rapid spread is possible if spores accidentally lodge on cargo or airline passengers.

FIGURE 49.4 The spread of Ug99

Ug99 is a highly damaging stem rust of wheat and a major threat to global food

production. It originated in Uganda and has spread to places indicated by the red circles.

Source: https://rusttracker.cimmyt.org/?page_id=22

Just before his death in 2009, Norman Borlaug urged the world to take this threat seriously. Today, plant breeders are actively searching ancestral wheat varieties for genetic sources of resistance to Ug99, while other scientists try to understand how plants defend themselves against rusts and what makes Ug99 so virulent.

Nicolai Vavilov, a Russian botanist

and geneticist, was one of the first to recognize the importance of safeguarding the genetic diversity of crop species and their wild relatives. In the early twentieth century, he mounted a series of expeditions to collect seeds from around the globe. Vavilov's observations of cultivated plants and their relatives led him to hypothesize that plants had been domesticated in specific locations. He called these regions centers of origin and they are shown in **FIGURE 49.5**. He believed that they coincided with the centers of diversity for both crop species and their wild relatives. From these locations, plant domestication spread through human migration and commerce. In World War II, during

the siege of Leningrad, scientists at the Vavilov Institute sought to protect what was then the world's largest collection of seeds. The dedication of these scientists illustrates the priceless nature of the genetic diversity on which our food supply rests.

FIGURE 49.5 Centers of origin for crops

The colored areas indicate where different crop species were first domesticated. They represent places where we might be able to find natural populations of our cultivated crops with high levels of genetic variation.

Today, seed banks help to preserve the genetic diversity of crop species and their wild relatives. One of the most significant seed banks is Svalbard Global Seed Vault, which was started in 2008 and currently holds approximately 6000 species of plants. However, seed banks can store only a fraction of the genetic diversity present in nature. To help make up the difference, some have suggested establishing protected areas that coincide with Vavilov's centers of origin. The resurgence of *P. graminis* and other fungi as serious threats to world food production underscores the importance of safeguarding the genetic diversity of agricultural species so that the evolutionary

battles with pathogenic species may be waged successfully.

The examples of corn, bananas, and wheat all focus on crops that have low levels of genetic variation because they have been bred this way by humans. In natural populations, we often see little genetic variation in populations that have undergone a population bottleneck. Recall from Module 43 that a population bottleneck occurs when a large population is reduced to a few individuals, which can happen after a sudden environmental change, such as a severe drought or large storm. As the number of individuals decreases, so does the level of genetic variation

that the population harbors. Similarly, genetic variation is often reduced significantly in the case of a founder effect, in which a new population is founded by a few individuals, also discussed in Module 43. Following a bottleneck or founder effect, the level of genetic variation will increase over time as the population grows, but this process occurs slowly because it depends on the occurrence and spread of new mutations.

For example, a recent study examined levels of genetic variation in platypuses (*Ornithorhynchus anatinus*) on two islands. Populations on islands tend to be small and isolated from the mainland, so they often begin with

low levels of genetic variation. Inbreeding and genetic drift can reduce genetic diversity even further. In the study, the researchers found very low levels of genetic variation among platypuses on these islands compared to mainland populations. Like island species, many endangered species also have little genetic variation because of their small population size. Examples of endangered species with low levels of genetic variation include sea otters (*Enhydra lutris*), cheetahs (*Acinonyx jubatus*), and Tasmanian devils (*Sarcophilus harrisii*).

AP® EXAM TIP

PREP FOR THE AP® EXAM

Remember that low genetic diversity makes a population more vulnerable to any stress, such a disease, drought, extreme temperatures, or increased predation.

✓ Concept Check

1. **Describe** why populations with little genetic variation are at risk of decline or extinction.

2. **Identify** a group of organisms that has very little genetic variation.

Photo: Anna Omelchenko/Dreamstime.com

49.2 Populations with high levels of genetic variation are often resilient to environmental change

Just as populations with little genetic variation are at risk of decline or even

extinction due to a change in the environment, such as the introduction of a pathogen, populations that have a lot of genetic variation are more resilient. These populations harbor genetic variants that may not be beneficial at any given time, but may be beneficial if the environment changes. Most natural populations have high levels of genetic variation as a result of mutation and recombination that have occurred in the past.

We can see the different effects of low and high genetic variation from a study of large cats. Cheetahs, shown in **FIGURE 49.6**, have very little genetic variation in part due to their

low population size and in part due to a population bottleneck they went through about 10,000 years ago. This event coincided with the end of last ice age, so it was likely the result of global climate change, and it caused declines or extinctions of many large mammal species. In 1982, a virus swept through a large cat breeding facility in Oregon. All of the cheetahs were infected and, after 3 years, 60% of the cheetahs died. By contrast, lions in the same facility, with much higher genetic variation, did not become ill. Presumably, the lions had gene variants (alleles) that provided protection against the virus and such variants were absent among the cheetahs.

FIGURE 49.6 Low levels of genetic variation in cheetahs

Cheetahs have very little genetic diversity because of a population bottleneck that occurred in the past and their small population size today.

Bacteria provide another example. In Module 41, we discussed antibiotic-sensitive and antibiotic-resistant bacteria. Imagine a population of genetically identical bacteria, all of which are sensitive to an antibiotic. In this case, application of an antibiotic represents a change in the environment. Due to their genetic uniformity, all the bacteria will be wiped out by the antibiotic.

Now imagine a population in which some bacteria are sensitive and some bacteria are resistant to an antibiotic. Because resistance to antibiotics has a genetic basis, the bacteria are genetically different from one another. In this case, application of the antibiotic will not kill all the bacteria. There will be differential reproductive success, with those bacteria that are antibiotic resistant surviving and reproducing better than the bacteria that are antibiotic sensitive. Over time, the population will evolve so that all the bacteria are resistant to the antibiotic. This is natural selection in action.

If a second antibiotic is now applied

to the bacteria, one that works differently from the first, the population will again be vulnerable. However, the more genetic variation the population of bacteria has, the more likely it will harbor a genetic variant that causes it to be resistant to an antibiotic that we use. The presence of this variant will allow the population of bacteria to evolve resistance over time when we apply antibiotics. Essentially, we are selecting for antibiotic-resistant bacteria.

In fact, this is the history of the use of antibiotics. Every time we use a new antibiotic, it is effective, but only for a short time, as the population of

bacteria evolve resistance as a result of preexisting mutations that were already present in the population. These mutations are then selected by our use of antibiotics. Today, antibiotic resistance is fast becoming a public health crisis, as bacteria are being found that are resistant to all known antibiotics. This is the result of applying antibiotics to a population of bacteria that have a lot of genetic variation.

In addition to allowing a population to adapt if the environment changes, genetic variation might allow members of a species to live in a range of different environmental conditions that are already present.

For example, consider an allele that is favored by natural selection in a dry environment and a different allele that is favored by natural selection in a wet environment. A species with both alleles will be well adapted to live in both environmental conditions, whereas a species with one or the other would be limited to just one condition.

This form of natural selection which acts to maintain two or more alleles of a given gene in a population is called balancing selection. This is different from earlier examples where we saw beneficial alleles increase in frequency in the population or harmful alleles

decrease in frequency under the influence of natural selection. In balancing selection, by contrast, both alleles are maintained in the population at some intermediate frequency.

49.3 Variants that are well adapted to one environment may not be well adapted in another environment

As we discussed in Module 41, the fitness of a particular variant depends in part on the variant and in part on the environment in which it is found. As a result, a genetic variant that is beneficial in one environment may not be beneficial or in fact may be harmful in a different environment. As an example, let's consider malaria.

Malaria is a disease that causes intermittent fevers, headaches, and sometimes death. It is caused by a parasite that is transmitted by mosquitoes. The malaria parasite spends part of its life cycle in human red blood cells. Within these cells is a molecule called hemoglobin, which carries oxygen and affects the structure of red blood cells.

Hemoglobin is made up of four subunits, including β-(beta-)globin. Mutations in β-globin can have a negative effect on the malaria parasite. For example, consider the *A* and *S* alleles of the β-globin gene, discussed in Module 37. The *A* allele has a GAG codon that translates to

glutamic acid (Glu) in the resulting protein. The *S* allele is a mutation that changes glutamic acid (Glu) to valine (Val). Although only one amino acid of the β-globin protein is affected, this change has a dramatic effect on the form and function of the protein, since the amino acid sequence determines how a protein folds, and protein folding in turn determines the protein's function, as discussed in Module 4.

For the *A* and *S* alleles, there are two homozygous genotypes, *AA* and *SS,* and one heterozygous genotype, *AS*. In *AA* individuals, a normal form of hemoglobin is produced. As a result, the red blood cells are round and fully

functional, as shown on the left in **FIGURE 49.7**. In *SS* individuals, the hemoglobin that is produced causes the red blood cell to distort into a half-moon or sickle shape, shown on the right in Figure 49.7. In this form, the red blood cell is unable to carry the normal amount of oxygen. In addition, the sickled cells can block small capillaries, interrupting the blood supply to vital tissues and organs, which causes debilitating, painful, and sometimes fatal episodes. This condition is called sickle-cell anemia. *AS* individuals have mild anemia, called sickle-cell trait. Sickle-cell trait is less severe than sickle-cell anemia, but, like all forms of anemia, it reduces the ability

of red blood cells to carry oxygen to tissues and organs, and so reduces the health of the individual.

FIGURE 49.7 Healthy and sickle-shaped red blood cells

A healthy red blood cell is shown on the left, and a sickle-shaped red blood cell is shown on the right. Red blood cells contain hemoglobin, which carries oxygen to tissues and organs. The sickle-shaped red blood cell results from a single mutation in the gene encoding a subunit of hemoglobin and results in the disease called sickle-cell anemia.

These three genotypes also differ in their susceptibility to malaria. *AA* individuals are healthy, but are susceptible to infection by malaria.

AS individuals have mild anemia, but have some protection against infection by malaria. *SS* individuals also have protection against infection by malaria, but have severe anemia. In areas where malaria is prevalent, *AS* individuals have higher fitness than either of the homozygotes because they only have mild disease and are protected from malaria. As a result, natural selection acts to maintain both the *A* and *S* alleles in the population. This form of natural selection is called heterozygote advantage. It is a form of balancing selection because, like the example we discussed in the last section, both alleles remain in the population at intermediate frequencies.

In areas where there is no malaria, however, this balance is shifted. While *AS* is favored by heterozygote advantage in areas with malaria and is therefore the most fit genotype, it is not favored in malaria-free regions. In this case, *AA* is favored and is the most fit genotype. The *AS* and *SS* genotypes have lower fitness in areas without malaria than the *AA* genotype because they both cause anemia, although to different degrees, and there is no advantage to carrying the *S* allele when malaria is not present. So, a genetic variant that is favored in one area is not in another.

Many people whose ancestors came from regions where malaria was

prevalent but now live in a malaria-free environment still carry the *S* allele, even though the allele is no longer beneficial to them in their current environment. If natural selection were to run its course among these people, the *S* allele would gradually be eliminated because it causes anemia as a heterozygote and homozygote. This is a slow process, however, and many more people will continue to suffer from sickle-cell anemia before it is eliminated from the population. Fortunately, medical interventions are available that can help those affected with the disease.

A second example of a genetic variant

being beneficial in one environment but not in another is antibiotic resistance in bacteria. A bacterium that has resistance to a particular antibiotic will likely not have resistance to a different type of antibiotic. The mutation that provides resistance is beneficial in one environment, but neutral or even harmful in a different environment. Both examples remind us that being well adapted, or having high fitness, depends on the environment, as we discussed in Module 41.

✓ Concept Check

5. **Describe** why *AS* individuals are well adapted to regions where there is malaria.

6. **Describe** why *AA* individuals are well adapted to regions without malaria.

7. **Describe** why a variant that is beneficial in one environment may not be beneficial in another.

Module 49 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

SYSTEMS INTERACTIONS: Using one example from the module, **provide**

evidence that a diverse gene pool increases the likelihood that a species will survive in the face of a changing environment.

LG 49.1 Populations with low levels of genetic variation are at risk of extinction.

- Populations that are genetically uniform are vulnerable to a change in the environment. Page 694
- Many crop species, such as corn and wheat, harbor very little genetic variation and so are vulnerable to new pathogens. Page 696

LG 49.2 Populations with high levels

of genetic variation are often resilient to environmental change.

- Populations of individuals that are genetically different have a better chance of withstanding changing environment. Page 698
- Antibiotic resistance among bacteria is a public health crisis because some bacteria are genetically variable and have evolved resistance to all known antibiotics. Page 699

LG 49.3 Variants that are well adapted to one environment may not be well adapted to another environment.

- Variants that are well suited to

one environment may not be well suited to a different environment. Page 700

- The *S* allele of β-globin provides protection against malaria in *AS* individuals, so it is beneficial as a heterozygote, but only in malaria-prone regions. Page 700

Review Questions

1. Which population is likely to be most resilient to a changing environment?

A. A population with very little genetic variation
B. A population in which individuals are genetically identical
C. A population with a lot of

genetic variation

D. A population that is genetically uniform

2. Variation is important for evolution and the ability of organisms to adapt to an environment because

A. it increases the likelihood that the population will go extinct.
B. it is the raw material on which evolution acts.
C. it is the source of harmful mutations.
D. it makes individuals of a population all the same.

3. Ug99 is a

A. fungus that infects wheat.
B. bacterium that infects

bananas.

C. protist that infects humans.

D. virus that infects the malaria parasite.

4. Most of the crops we eat are

A. genetically diverse.

B. genetically uniform.

C. made up of individuals that are genetically different from one another.

D. relatively resistant to new pathogens.

5. In areas where malaria is present, which genotype is the most fit?

A. *AA*

B. *AS*

C. *SS*

D. *AAA*

6. In areas where malaria is absent, which genotype is the most fit?

A. *AA*
B. *AS*
C. *SS*
D. *AAA*

7. Genetic variation is ultimately the result of

A. natural selection.
B. genetic drift.
C. migration.
D. mutation.

Module 49 AP® Practice Questions

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–3.

1. Which of the following describes a reason why small populations have a higher risk of extinction?

   A. Genetic drift is a weaker force in small populations.
   B. Individuals in small populations often choose not to reproduce with close relatives.
   C. Small populations are more vulnerable to high levels of

predation.

D. Small populations lack genetic variation that enables adaptation to changing environments.

2. Which of the following statements about environmental variation is most accurate?

A. Different natural selective pressures in different environments can maintain genetic variation in populations.

B. Environmental change cannot increase genetic variation in populations because natural selection acts on individuals.

C. Environmental change usually

increases genetic variation because natural selection drives novel mutations to fixation.

D. Environmental change leads to extinction because genetic diversity prevents adaptation.

3. Which of the following statements about heterozygote advantage is most accurate?

A. Heterozygote advantage is most common in haploid organisms like bacteria.

B. Heterozygote advantage can only occur when one of the alleles is dominant.

C. Heterozygote advantage occurs when a heterozygote has

higher fitness than all homozygotes.

D. Heterozygote advantage often leads to the formation of new species.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Common frogs (*Rana temporaria*) are amphibians. Because they can live both on land and in water, adult frogs can move between different bodies of water. Adult frogs lay their eggs in

water, and when the eggs hatch, the tadpoles remain in the water until they undergo metamorphosis to become adult frogs. Thus, the aquatic environment imposes a strong evolutionary pressure on the frogs.

A researcher hypothesized that some genotypes of *R. temporaria* might have higher fitness than others in different aquatic environments. To test this hypothesis, the researcher collected frog eggs from a pond with high levels of salt, or salinity. The researcher also collected eggs from a pond with low salinity. The frogs in these two ponds are known to be genetically different from each other.

The researcher transferred half of the eggs from each collection into a high-salinity aquarium in the lab, and the other half into a low-salinity aquarium in the lab. After the eggs hatched, the researcher measured the proportion of tadpoles from each collection that survived to metamorphosis in each aquarium. The data that the researcher obtained are illustrated in the figure.

a. **Identify** the source of the eggs that have the highest survival to metamorphosis in the high-salinity aquarium.
b. The researcher makes a claim that the egg genotypes in each

pond are adapted to their native salinity environment. **Provide reasoning** to support or refute this claim.

c. Environmental factors like salinity can be highly variable over geography and over time. **Explain** why genetic diversity can help populations survive environmental change and avoid extinction.

Module 50

Origin of Life on Earth

LEARNING GOALS

- **LG 50.1 The building blocks of organic molecules can be synthesized from inorganic precursors.**
- **LG 50.2 The formation of organic molecules set the stage for the first cell.**
- **LG 50.3 Life originated on Earth at least 3.5 billion years ago.**
- **LG 50.4 The history of life was mostly unicellular, with familiar organisms appearing later.**

In the preceding 10 modules, we have explored the process of evolution. We have described how life changes over time, and discussed mechanisms by which this change occurs. We have seen how one of these mechanisms—natural selection—can account for the remarkable adaptations all around us. The evolution of life on Earth began with the very first cell—the first form of life—and continues today.

Where did life come from in the first place? This is a fascinating question and is the subject of much research. The question is also intimately connected with the search for life on other planets, such as Mars. If we

understand the conditions in which life arises, perhaps we will have a better chance of finding it elsewhere in our solar system or the universe.

It's important to emphasize that the process by which life evolves is not the same as the process by which life originates. These are distinct and separate processes. Life evolves by the five mechanisms we discussed in Module 43—natural selection, genetic drift, migration, mutation, and nonrandom mating. We have a good understanding of these processes and can explain them in detail. By contrast, the process by which life arises from nonliving materials—called abiogenesis—does not occur by

the evolutionary mechanisms we have explored and is not as well understood.

To understand how life first arose, let's work backward. As we saw in Unit 2, the smallest living entity is the cell. This is why the cell is considered the fundamental unit of life. Anything smaller is not alive. So, the question of how life originated becomes: how did the first cell arise? Cells have certain features, such as the ability to store and transmit information, maintain homeostasis, and harness energy from the environment, so we can ask: how did these functions emerge? Finally, cells are made up of organic molecules, such as proteins,

nucleic acids, carbohydrates, and lipids, so we can ask: how were these molecules first made?

In this module, we will consider how life originated on this planet by working forward through these steps —How were organic molecules synthesized on the young Earth? How did they perform functions essential for life? And how did they come together to build the first cell? We will end with a brief overview of what happened after that time, which comprises the history of life on Earth.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

SYSTEMS INTERACTIONS: Look for connections between the chemical building blocks available on the early Earth and the organic molecules necessary for life.

50.1 The building blocks of organic molecules can be synthesized from inorganic precursors

Estimates of the age of Earth indicate that it formed about 4.6 billion years ago. Analyses of ancient rocks, dated to within 0.3 billion years of Earth's formation, suggest that the early Earth was markedly different from

Earth today. For instance, the young Earth was very hot and had a lot of volcanic activity. Liquid water is thought to have been first present anywhere from shortly after the planet was formed to 4.3 billion years ago. This is relevant to life's origin because water is essential to life as we know it. In fact, where we find water, we often find life. In this section, we will look at the environment of the young Earth and describe the types of molecules that were present.

The Atmosphere of Ancient Earth

Geological evidence suggests that a number of molecules existed early in

Earth's history. These included relatively large amounts of the gases carbon dioxide (CO2)(CO_2) and nitrogen (N2)(N_2), with smaller amounts of carbon monoxide (CO) (CO), hydrogen (H2)(H_2), hydrogen sulfide (H2S)(H_2S), ammonia (NH3) (NH_3), and methane (CH4)(CH_4).

A notable absence was oxygen gas (O2)(O_2), which today makes up approximately 21% of Earth's atmosphere. Because oxygen is now present in our atmosphere, we have what is sometimes called an oxidative atmosphere. This description refers to oxygen's highly reactive properties that allow it to react with a large number of compounds. For example,

when iron is exposed to oxygen and a little moisture, it quickly oxidizes and becomes rust, a familiar site on many cars as shown in **FIGURE 50.1a**. Similarly, hydrogen gas (H2)(H_2) explodes when it reacts with oxygen, releasing large quantities of energy, as dramatically demonstrated when the *Hindenburg*, filled with hydrogen gas, burst into flames as shown in Figure 50.1b.

Figure 50.1 The reactivity of oxygen

Oxygen reacts with a large number of chemicals. (a) Rust forms on metals like cars when oxygen and water react with iron. (b) The *Hindenburg* was an airship called a zeppelin filled with hydrogen gas to keep it afloat. It burst into flames

in 1937 when oxygen in the air reacted with hydrogen gas as it attempted to dock.

In contrast to the oxidative atmosphere that we are familiar with, the atmosphere of ancient Earth was what is called a reducing atmosphere because of the lack of oxygen gas. The absence of oxygen gas was significant because of oxygen's reactive properties. Its presence in the early Earth's atmosphere would likely have destroyed any newly made molecules that had been synthesized from the other chemicals that were present. Therefore, any chemicals formed before the presence of oxygen gas would have been far more stable. The

stability of the newly formed, ancient molecules could then lead to further reactions that could synthesize the molecules necessary for life.

The Building Blocks of Organic Molecules

As we saw in Unit 2, the molecules of life, or organic molecules, include proteins, nucleic acids, carbohydrates, and lipids. As we discussed, these molecules are made up of simpler molecules joined together. Proteins are made up of amino acids; nucleic acids are made up of nucleotides; carbohydrates are made up of simpler sugars; and some lipids are made up of glycerol and

fatty acids. To understand how these organic molecules may have emerged on the early Earth, we first need to understand how these building blocks formed. Thus, if we want to understand how proteins formed, we should begin with the synthesis of amino acids, and if we are interested in nucleic acids, we should focus on nucleotides.

Research into the origins of life was catapulted into the experimental age in 1953 with an elegant experiment carried out by Stanley Miller, then a graduate student at the University of Chicago in the laboratory of Nobel laureate Harold Urey. This experiment is outlined in "Practicing

Science 50.1: Could the building blocks of organic molecules have been generated on the early Earth?”

Miller started with water vapor, methane (CH4)(CH_4), ammonia (NH3)(NH_3), and hydrogen gas (H2)(H_2)—all of which are thought to have been present in the early atmosphere. He put these gases into a sealed flask and then passed a spark through the mixture. On the primitive Earth, lightning or volcanic heat might have supplied the energy needed to drive chemical reactions, and the spark was meant to simulate these effects. Analysis of the contents of the flask showed that several amino acids were generated.

Practicing Science

50.1

Could the building blocks of organic molecules have been generated on the early Earth?

PREP FOR THE AP® EXAM

Background In the 1950s, it was widely believed that Earth's early atmosphere was rich in water vapor, methane, ammonia, and hydrogen gas, with no free oxygen.

Experiment Stanley Miller built an apparatus, illustrated in the figure, designed to simulate Earth's early atmosphere. He began by heating liquid water to produce water vapor (H2O) (H_2O). This water vapor then mixed with other gases thought to be present on the

early Earth, including methane (CH4) (CH_4), ammonia (NH3)(NH_3), and hydrogen gas (H2)(H_2). To simulate lightning, Miller passed a spark through the mixture of gases. The gas mixture was then cooled, allowing liquid water to form again and dissolve any molecules that were synthesized. These were collected at the bottom of the apparatus and obtained through a sampling valve for analysis.

Results As the experiment proceeded, reddish material accumulated at the bottom of the apparatus. Analysis showed that this material included a number of amino acids, the building blocks that make up proteins, which are the key structural and functional

molecules that do much of the work of the cell.

Conclusion Amino acids can be generated in conditions that mimic those of the early Earth.

Follow-up Work Recent analysis of the original extracts, saved by Miller, shows that the experiment produced about 20 different amino acids, not all of them found in organisms.

SOURCES:
Miller, S. L. 1953. "Production of Amino Acids under Possible Primitive Earth Conditions." *Science* 117:528–529; Johnson, A. P., et al. 2008. "The Miller Volcanic Spark Discharge Experiment." *Science* 322:404.

AP® PRACTICE QUESTION

a. **Identify** the following:

1. The question being investigated by the experimenters
2. The hypothesis they tested
3. The independent variable
4. The dependent variable
5. Future testable questions that arise in light of the results of this experiment

b. **Explain** the results of the experiment by **identifying** the researchers' claim and **justifying** the claim with the evidence and the reasoning researchers used (CER).

Recall that amino acids are the basic units from which proteins are made. Their synthesis in the laboratory under conditions that mimic the early Earth opens the possibility that amino acids could have been made on

ancient Earth in a similar way. We now know that amino acids can be used by today's cells to make not only proteins but also the nucleotides required for DNA and RNA synthesis. While such a pathway was unlikely to have existed at the time, the synthesis of amino acids from basic inorganic molecules, as demonstrated by Miller and Urey's experiment, supports the concept that the basic units of organic molecules could have been formed on ancient Earth prior to the existence of living organisms.

Miller and others conducted many variations on his original experiment, all with similar results. Later experiments showed that other

chemical reactions can generate nucleotides, simple sugars, and lipids. For example, in 2009, John Sutherland and his colleagues synthesized nucleotides from their sugar, base, and phosphate components.

Another striking observation comes from examining meteorites. Meteorites provide chemical samples of the early solar system. Analyses of certain meteorites have found a variety of different molecules, including amino acids. Finding these molecules on meteorites brings up the possibility that the building blocks of organic molecules were synthesized in space and brought to Earth by a meteorite.

Whether formed in space or on Earth, it's clear that the building blocks of organic molecules can be built by chemical reactions from even simpler chemicals such as water, H2H_2, CH4 CH_4, CO2CO_2, N2N_2, and NH3NH_3 in the absence of life. Furthermore, these observations provide evidence that the building blocks of organic molecules can be synthesized under conditions thought to resemble those at the time of the young Earth.

AP® EXAM TIP

PREP FOR THE AP® EXAM

When answering a free-response question, be sure to include the relevant data to support your answer. For example, if asked how

amino acids might have formed before any cells existed on Earth, you should cite that chemicals such as CO_2, N_2, CO, H_2, H_2S, NH_3, and CH_4 were present in the ancient atmosphere, and that energy, such as from lightning or volcanoes, could have been the catalyst that caused these chemicals to react and produce amino acids among the products.

50.2 The formation of organic molecules set the stage for the first cell

We have discussed some of the evidence that life's building blocks can be generated under conditions likely to have been present on the early Earth. In this section, we will consider how these subunits can be

linked to form larger molecules, such as proteins, nucleic acids, and carbohydrates. These molecules are called polymers, which are large molecules made up of smaller subunits repeated over and over.

Synthesis of Organic Molecules

Today we know that cells synthesize many polymers such as proteins using dehydration synthesis reactions, as we discussed in Module 4. Careful experiments have shown how polymers could have formed in the conditions of the early Earth. Researchers have demonstrated that dry mixtures of amino acids, when

heated sufficiently, will join and form larger molecules, effectively demonstrating that proteins can be synthesized from their basic units.

Another important observation that helps us understand how subunits could have assembled into polymers on the young Earth comes from clay minerals, pictured in **FIGURE 50.2**. Clay minerals form from volcanic rocks and are able to bind nucleotides on their surfaces in such a way that nucleotides are placed near one another. As a result, the nucleotides are able to form bonds and form chains or single strands of nucleic acids like RNA.

FIGURE 50.2 Surface for the

spontaneous polymerization of nucleotides

The image shows stacked sheet like crystals of clay from Australia. Each layer is about 8 microns wide. Clays, such as the one shown here, provide a surface on which individual nucleotides can join, or polymerize, to form nucleic acids.

Following up on the observation that a single strand of nucleic acid can be built on clay minerals, British biochemist Leslie Orgel wondered whether a single strand of nucleic acid, however it may have been formed, could serve as a template for synthesis of a complementary strand. In a classic experiment, he placed a

short nucleic acid sequence into a tube and then added individual nucleotides that had been chemically modified to join, or polymerize, if brought close together. The added nucleotides did polymerize, and they did so in a way to form a sequence complementary to the nucleic acid already present, as shown in **FIGURE 50.3**. In the first panel, we see the single-stranded nucleic acid and added nucleotides. In the second panel, we see the growing strand that is complementary to the template strand. In the third panel, we see both the template strand and the newly synthesized daughter strand.

FIGURE 50.3 Spontaneous polymerization of nucleotides

Addition of a short RNA molecule (the template strand) to a flask containing nucleotides results in the formation of a complementary RNA strand.

RNA World

For life to arise on Earth, a critical step was the synthesis of a molecule that could store information and pass it on through the process of replication. In this way, a cell would be able to reproduce and pass traits from parental to daughter generations. Of all the molecules present in cells today, only nucleic acids have the ability to be replicated and passed to daughter cells.

Today, DNA serves the function of storing and transmitting information present in cells, as we discuss in Module 32. RNA, like DNA, is made up of nucleotides, can store information in its sequence of nucleotides, and is able to make copies of itself by serving as a template for a daughter strand. In addition, RNA has one function that DNA does not have: some RNA molecules actually act as enzymes that facilitate chemical reactions. Such RNA molecules are called ribozymes and act as catalysts in biochemical reactions.

Ingenious experiments carried out by Jack W. Szostak and collaborators showed how RNA could have evolved

the ability to catalyze a simple reaction. These researchers synthesized a strand of RNA in the laboratory and then replicated it many times to produce a large population of identical RNA molecules. Next, they exposed the RNA to a chemical that induced random changes in the identity of some of the nucleotides in these molecules. These random changes were mutations that created a population of diverse RNA molecules, much in the way that mutation builds genetic variation in cells.

Next, the researchers placed all these RNA molecules into a tube, and those RNA variants that successfully

catalyzed a simple reaction—cleaving a strand of RNA, for example, or joining two strands together—were isolated, and the cycle was repeated. In each round of the experiment, the RNA molecules that functioned best were retained, replicated, subjected to treatments that induced additional mutations, and then tested for the ability to catalyze the same reaction. With each generation, the RNA catalyzed the reaction more efficiently, and after only a few dozen rounds of the procedure, very efficient RNA catalysts had evolved.

Experiments such as these suggest that RNA molecules can evolve over time and act as catalysts. This type of

experimental evidence has led many scientists to conclude that RNA, with its dual functions of information storage and catalysis, was a key molecule in the very first forms of life.

Because RNA has properties of both DNA (information storage and transmission) and proteins (enzymes), many scientists think that RNA, not DNA, was the original information-storage molecule in the earliest forms of life on Earth. This idea is known as the **RNA world hypothesis**. The RNA world hypothesis is supported by other evidence as well. Notably, as we discussed in earlier modules, RNA is

involved in key cellular processes, including DNA replication (Module 32), transcription (Module 33), and translation (Module 34). Many scientists think that this involvement is a vestige of a time when RNA played a more central role in life's fundamental processes.

If RNA played a key role on ancient Earth, why do cells now use DNA for information storage and proteins to carry out many other cellular processes? RNA is much less stable than DNA, and proteins are more versatile catalysts, so a reasonable hypothesis is that life evolved from an RNA-based world to one in which DNA, RNA, and proteins are

specialized for different functions.

✓ Concept Check

3. **Describe** the importance of experiments that showed nucleic acids and proteins can be made by the polymerization of their respective building blocks.

4. **Describe** the significance of experiments that demonstrated certain RNAs have catalytic activities.

50.3 Life originated on Earth at least 3.5 billion years ago

Up to this point, we have discussed how organic molecules formed on the early Earth and we have paid special attention to RNA. As we saw, scientists have gathered evidence suggesting that RNA, rather than DNA, stored information in early cells. Very likely, RNA performed other functions in early cells as well,

catalyzing chemical reactions much as proteins do today. However, all life as we know it is cellular. Biologists express this idea as the cell theory. The cell theory states that the cell is the basic unit of life and that all organisms are made up of cells. Today, all cells come from pre-existing cells, which brings up an important question: how and when did the first cell arise on ancient Earth?

This is one of the biggest questions in biology. Chemical evidence from 3.5-billion-year-old rocks in Australia indicates that biologically based carbon and sulfur cycles existed at the time those rocks formed. Because

living organisms drive these cycles, life must have been established then, and therefore originated even earlier. Evidence from other continents appears to push the origin of life back to 3.8 billion years or even earlier.

All cells require an archive of information, a membrane to separate the inside of the cell from its surroundings, and the ability to harness energy from the environment. We have already discussed the earliest information-storing molecule. In this section, we will focus on how simple membranes and metabolisms might have originated.

Early Cell Membranes

All cells, whether found as single-celled bacteria or by the trillions in trees or humans, are individually encased in a cell membrane, or plasma membrane. Membranes are made up of lipids, specifically phospholipids, among other molecules. Research shows that phospholipids possess properties that may have led them to form spontaneously on the early Earth. As we discussed in Unit 2, phospholipids are able to form micelles, liposomes, and lipid bilayers when placed in water. If the conditions are appropriate and certain phospholipids are present, bilayer

structures form spontaneously and without the action of an enzyme. For example, if phospholipids are added to a test tube of water at neutral pH, they spontaneously form spherical bilayer structures called liposomes that surround a central space. A liposome is shown in **FIGURE 50.4**. This observation is significant, as it suggests that cell-like structures might have formed spontaneously on the early Earth.

FIGURE 50.4 A liposome

Phospholipids can form liposomes when placed in water. Liposomes have a central fluid-filled space and so may have been the precursor of the first cell.

Such processes may have been at work in the early evolution of life on Earth. Experiments have shown that liposomes can form, break, and re-form in environments such as tidal flats that are repeatedly dried and flooded with water. Liposomes can even grow, incorporating more and more lipids from the environment, capturing nucleic acids and other molecules in their interiors. Note that a liposome is a sphere, with a fluid-filled space in its interior. Thus, when liposomes form, they may capture molecules present in solution. A critical step in the formation of a cell might have occurred when a liposome captured a self-replicating RNA.

At first, the membranes were probably quite simple—straightforward but leaky barriers that kept the contents of early cells separated from the outside world. Over time, as chance variations arose, those membranes that provided a better barrier were favored by natural selection. Moreover, proteins became embedded in membranes, providing gates or channels that regulated the transport of ions and small molecules into and out of the cell. In this way, early organisms gained the capacity to regulate cell interiors—what biologists call homeostasis. Homeostasis, as we saw in Unit 2, is the active maintenance of a steady internal environment of cells and

organisms, even when the external environment changes.

Given that Earth existed for approximately 800 hundred million years before geological evidence suggests that life arose, it is possible that self-replicating RNAs could have been encapsulated by liposomes numerous times and that a prototype "first cell" was made. Evidence thus suggests that membranes formed originally by straightforward physical processes and that their composition, complexity, and functions evolved over time to yield what exists today.

Early Cell Metabolisms

In addition to storing information and maintaining homeostasis, a third essential characteristic of living things is the ability to harness energy from the environment. Here, too, a series of natural chemical processes might have led to cells that could achieve this feat. Simple reactions that produced carbon-containing molecules as by-products would have enabled more complex reactions down the road. Ultimately, that collection of reactions—combined with an archive of information and enclosed in some kind of primitive membrane—evolved into individual units that could grow, reproduce, and evolve.

Metabolism is the set of all the chemical reactions a cell requires and the capturing of the energy necessary to perform those reactions, as we discussed in Module 13. An ancient cell, even one with a primitive metabolism, would have a definite advantage compared to those cells that lacked a metabolism. While it is not known for sure, we can speculate on how a metabolism may have been gained by an ancient cell.

One of the simplest types of metabolism known today is fermentation. Recall from Unit 3 that fermentation is a process that extracts energy from organic molecules but does not require

oxygen, so is anaerobic. There are many different fermentation reactions, all of which begin with glycolysis. Glycolysis breaks down a molecule of glucose into two molecules of pyruvate, generating ATP and NADH. Fermentation reactions then regenerate NAD+ NAD^+ from NADH and allow the process to continue. Notably, these reactions do not require oxygen gas (O2)(O_2) and thus could have occurred on ancient Earth as a way for early cells to generate ATP.

A second type of metabolism is anaerobic respiration, which is respiration that occurs without oxygen. Respiration reactions involve

an electron transport chain in which electrons are removed from one molecule and delivered to another molecule, an electron acceptor, that is not derived from the original molecule. In the process, energy is released and ATP is synthesized for use by the cell. Anaerobic respiration probably evolved later than the fermentation reactions, but the two metabolic processes were likely important for the function of early cells on the young Earth.

A third type of early metabolism is photosynthesis. In photosynthesis, light energy is used to excite electrons and move them from one compound to another, in the process releasing

energy. In Unit 3, we discussed a form of photosynthesis in which oxygen is produced as a by-product, called oxygenic photosynthesis. Earlier forms of photosynthesis did not use water as a source of electrons and so did not produce oxygen gas. As with fermentation and anaerobic respiration, the energy released by photosynthesis can be captured, resulting in the production of ATP. Some bacteria today carry out photosynthesis that doesn't use water (H2O)(H_2O) as an electron donor; instead, they use other molecules, such as hydrogen sulfide (H2S)(H_2S). This form of photosynthesis, called anoxygenic photosynthesis, may also have

evolved relatively early in the history of life on Earth.

Once ancient cells acquired a metabolism, the path was set for cells to become more independent and self-sufficient. Metabolism would allow cells to exercise greater control over their interactions with their environments and to gain complexity that further supported their survival and reproduction. While the earliest cells were very likely to be primitive compared to today's existing cells, they would have captured the essential qualities of having a self-directed, reproducing heredity material; the ability to separate themselves from their environment;

and at least a rudimentary metabolism that provided a source of usable energy.

✓ Concept Check

5. **Identify** three essential functions of all cells.

6. **Describe** the significance of the observation that phospholipids can spontaneously assemble themselves into various structures, such as liposomes.

7. **Identify** one metabolic reaction that might have been present in the earliest cells.

50.4 The history of life was mostly unicellular, with familiar organisms appearing later

We have seen how organic molecules might have formed on the young Earth, and how they might have come together to form the first cell capable of storing information, maintaining homeostasis, and harnessing energy. It is difficult to say whether life

originated once and then continued to evolve over time, or whether it emerged and died off multiple times before it took hold. Either way, multiple lines of evidence support the idea that all organisms alive today descended from a single common ancestor. Life was certainly established 3.5 billion years ago, likely earlier, as shown in the timeline of Earth and life in **FIGURE 50.5**.

FIGURE 50.5 A timeline of the history of Earth and life

The Earth is 4.6 billion years old. Life originated at least 3.5 billion years ago. Other major events in the history of life are also shown on the timeline. Note that animals, plants, and other familiar

organisms evolved relatively late, with modern humans evolving only very recently and occupying just a tiny slice of time.

What did this universal common ancestor look like? It was prokaryotic: a single-celled organism without a nucleus. Modern descendants of these early life forms include two of the three great domains of life—Bacteria and Archaea. Note that the bacteria and archaea that are alive today are not the same as the ones that were present on the young Earth. Like all organisms, they have continued to evolve since their origin.

The first 2 billion years of life on Earth—almost half of the time life has existed on the planet—were dominated by these prokaryotic organisms, as can be seen from the timeline in Figure 50.5. It was a time of great diversification. The bacteria and archaea remained unicellular, but they evolved many different ways to gather materials and harness energy from the environment. Today, these prokaryotes cycle elements in diverse ways, and life as we know it would therefore not be possible without them.

One group of bacteria—cyanobacteria—evolved the ability to carry out oxygenic photosynthesis. As we saw

in Unit 3, oxygenic photosynthesis is the process in which energy from sunlight is used to build sugars from carbon dioxide and water. This form of photosynthesis is similar to earlier forms of photosynthesis, but by using water as the source of electrons, it produces oxygen gas as a by-product. So, for the first time, oxygen gas started to accumulate in the atmosphere. This event is indicated on the timeline in Figure 50.5 as the "First evidence of an oxygen-rich environment." As we discussed earlier in this module, O 2 CO_2 is a very reactive molecule. Therefore, although we take it for granted today and can't live without it, at the time, the accumulation of O 2 CO_2 in the

atmosphere represented a major crisis for life on Earth, earning the name oxygen catastrophe as many forms of life, adapted for an oxygen-free atmosphere, went extinct.

No other group evolved this ability—ever—in the history of life on Earth. It evolved just once in cyanobacteria. Organisms alive today, like plants and algae, that are also capable of oxygenic photosynthesis can only do so because they incorporated, in one way or another, these bacteria. For example, organelles called chloroplasts, where photosynthesis takes place in plants, were once free-living cyanobacteria, as we discussed in Module 12.

The next key event on the timeline of life in Figure 50.5 is the evolution of the third domain of life—the Eukaryotes—with cells that have a nucleus, like our own. This event occurred about 2 billion year ago, over half of the way along the timeline. These cells are the ancestors of our cells, but the organisms, like the bacteria and archaea that preceded them, were single-celled.

It took another billion years, about 1 billion years ago, before cells started getting together to form first simple and then more complex associations. Multicellularity didn't evolve once, but several times independently in different groups of organisms. For

example, it evolved one time in the line of organisms that led to modern-day plants, and it evolved separately in a different line of organisms that led to modern-day animals. Put another way, the common ancestor of plants and animals was unicellular, not multicellular.

About 541 million years ago, or roughly 90% of the way along Earth's timeline, there was a sudden appearance in the fossil record of many marine animals. This relatively rapid diversification of animals is called the Cambrian explosion, and it is marked on the timeline in Figure 50.5. We know about it from a remarkable set of fossils collected

from what is now British Columbia in Canada and called the Burgess Shale, as we discussed in Module 44. It preserves a record of early animal marine life.

Up until this time, life existed entirely in the oceans. The movement onto land presented many challenges for organisms that were adapted for aquatic life. Fungi and plants likely moved onto land first, followed by animals. The invasion of land required adaptation to a dry environment. The first land vertebrates were amphibians; reptiles, birds, and mammals evolved later, well after life was well established on land. And what about

us? Modern humans evolved just 200,000–300,000 years ago in Africa. In other words, all humans alive today can trace their ancestry back to Africa not that long ago. If the 4.6-billion-year history of the Earth played out over 60 seconds, we would only get a very tiny fraction of a second of time.

In short, the history of life on Earth is one with humble beginnings that eventually gave rise to the abundant diversity of life we see around us. This arc is described memorably by Charles Darwin in the final paragraph of *On the Origin of Species:*

> It is interesting to contemplate an entangled bank, clothed with

many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth, and to reflect that these elaborately constructed forms, so different from each other, and dependent on each other in so complex a manner, have all been produced by laws acting around us … There is grandeur in this view of life, with its several powers, having been originally breathed into a few forms or into one; and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being,

evolved.

✓ Concept Check

8. **Describe** the first cell.

9. **Describe** where oxygen in the atmosphere comes from and when in the history of life on Earth it first accumulated.

10. **Describe** the significance of the Cambrian explosion.

Module 50 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

SYSTEMS INTERACTIONS: Use one scientific theory from the module to **describe** how the chemical building blocks available on the early Earth might have been utilized to synthesize the components of the earliest cells.

LG 50.1 The building blocks of organic molecules can be synthesized from inorganic precursors.

- The age of the Earth is about 4.6 billion years. Page 704
- The early Earth had the inorganic molecules carbon dioxide, nitrogen gas, carbon monoxide, hydrogen gas, hydrogen sulfide, ammonia, and methane. Page 705
- Oxygen gas (O 2) (O_2) was absent during the early periods of Earth's history. Page 705
- Experiments indicate that the building blocks of organic molecules can be generated from inorganic molecules under conditions that mimic those of

ancient Earth. Page 707

- The building blocks of organic molecules are also found on meteorites. Page 707

LG 50.2 The formation of organic molecules set the stage for the first cell.

- Experiments suggest that polymerization of amino acids to form proteins and nucleotides to make nucleic acids could have occurred without cells being present. Page 707
- Some RNA molecules have catalytic activity and can therefore serve both as the template and the catalyst to make additional RNA molecules. Page

708

- The proposal that RNA was the original self-replicating, hereditary material is known as the RNA world hypothesis. Page 709

LG 50.3 Life originated on Earth at least 3.5 billion years ago.

- The earliest record of life is about 3.8 billion years ago, and it was certainly in place 3.5 billion years ago. Page 709
- Early cells required a way to store and transmit information, a membrane to separate inside from outside, and the ability to harness energy. Page 709
- The formation of liposomes from

phospholipids could have been the first cell membrane. Page 709
- This liposome might have encapsulated a self-replicating RNA molecule. Page 709
- Metabolism is the full set of biochemical reactions that are required to sustain life. Page 710
- Fermentation, anaerobic respiration, and photosynthesis, all of which produce ATP without the involvement of O 2 CO_2, may have been metabolic reactions present in early cells. Page 710

LG 50.4 The history of life was mostly unicellular, with familiar organisms appearing later.

- The first cells were prokaryotic.

Page 711

- Cyanobacteria evolved the ability to carry out oxygenic photosynthesis about 2.5 billion years ago, and oxygen gas accumulated in the atmosphere for the first time. Page 711
- Eukaryotic cells, which have a nucleus and other internal membranes, evolved around 2 billion years ago. Page 711
- Multicellularity evolved several times independently about 1 billion years ago. Page 711
- The Cambrian explosion was a great diversification of marine animals that occurred 541 million years ago. Page 711
- Humans appeared very recently,

approximately 200,000-300,000 years ago in Africa. Page 712

Key Term

RNA world hypothesis

Review Questions

1. Which chemical was not present in the ancient atmosphere of Earth?

A. Oxygen gas
B. Nitrogen gas
C. Ammonia
D. Carbon dioxide

2. Which statement does not support the RNA world hypothesis?

A. RNA can catalyze reactions.
B. RNA can make copies of itself.

C. RNA molecules can evolve to become more efficient.
D. RNA is unstable and degrades quickly.

3. Which is the fundamental unit of life?

A. A self-replicating molecule
B. A liposome
C. A cell
D. An organism

4. Based on the geological record, how long do scientists estimate it took for the first cells to appear on Earth?

A. 8 million years
B. 80 million years
C. 800 million years
D. 8000 million (8 billion) years

5. What was the significance of liposomes in the evolution of life on Earth?

A. Liposomes provided energy sources to the self-replicating RNA they contained.
B. Liposomes may have encapsulated a self-replicating RNA and provided protection from the environment.
C. Liposomes were the sites of protein synthesis in the first cells.
D. The phospholipids that make up liposomes were able to self-replicate, which led to the formation of cells.

6. Which best describes the role of

oxygen in the making of early organic molecules?

A. The lack of oxygen on the early Earth was necessary as organic molecules do not contain oxygen atoms.
B. The lack of oxygen gas on the early Earth provided an environment in which the building blocks of organic molecules were stable.
C. The presence of oxygen on the early Earth was necessary to act as a catalyst in the formation of the building blocks of organic molecules.
D. The presence of oxygen on the early Earth prevented predators from consuming the

organic molecules present.

7. Where did oxygen gas in the atmosphere first come from?

A. It was present in the atmosphere from the time of the formation of Earth.
B. It slowly seeped out of cracks in Earth and accumulated over time.
C. It was produced by lush rainforests.
D. It was produced by cyanobacteria.

Module 50 AP® Practice Questions

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–3.

1. Which of the following is an attribute of the early Earth atmosphere that might have contributed to spontaneous accumulation of organic molecules?

   A. Nitrogen gas was absent from the early Earth atmosphere, which could have enabled spontaneous formation of amino acids.
   B. Oxygen gas was absent from the early Earth atmosphere,

which could have lowered the rate at which organic molecules were degraded.

C. Nitrogen gas was present in the early Earth atmosphere, which could have enabled spontaneous formation of DNA.

D. Oxygen gas was present in the early Earth atmosphere, which could have increased the rate at which organic molecules were synthesized.

2. Which of the following is most likely to have been a metabolic process found in early forms of life on Earth?

A. Aerobic respiration

B. Krebs cycle
C. Fermentation
D. Calvin cycle

3. Which of the following most accurately describes the possible role of spontaneous liposome formation in the early evolution of life on Earth?

A. Liposomes could have served as primitive membranes for the Krebs cycle.
B. Liposomes could have provided mechanical structures that would bring enzymes into contact with their substrates.
C. Liposomes could have protected catalytically active

RNAs from the external environment.

D. Liposomes could have acted as essential intermediates in the synthesis of DNA.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Hydrogen cyanide and ammonia are chemicals that were abundant in the early Earth atmosphere. Scientists wanted to determine whether these chemicals could spontaneously react

to form molecules essential for life under early Earth conditions. The scientists mixed a limiting amount of hydrogen cyanide with a large excess of ammonia in a reaction flask and allowed the chemicals to react at 70°C (158°F) for 8 days. The scientists measured the amounts of adenine and hydrogen cyanide in the flask on days 0, 1, 3, 5, and 8 and obtained the data shown in the figure.

a. **Identify** two biologically important molecules that incorporate adenine.
b. **Predict** what would have happened to the level of adenine if additional hydrogen cyanide

had been added to the flask at day 4. **Provide reasoning** to support your prediction.

c. **Predict** what would have happened to the level of adenine if additional ammonia had been added to the flask at day 4. **Provide reasoning** to support your prediction.

d. **Explain** how the data from this experiment could be used to support the hypothesis that life on Earth originated from nonliving chemicals.

Unit 7

AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–15.

1. Which of the following provides the most complete definition of evolution?

   A. Any genetic change in a population over time
   B. An increase in the frequency of alleles that give adaptive benefits
   C. Creation of new genetic variation through mutation
   D. Phenotypic change in a species due to natural selection

2. Which of the following

statements about fitness is most accurate?

A. The fitness of an individual is always determined by its genotype.
B. Fitness is irrelevant to evolution when there is competition among individuals.
C. Individuals with the same phenotype could have different fitnesses in different environments.
D. Individuals with high fitness are not affected by genetic drift.

3. Nematodes are microscopic, soft-bodied worms that do not

fossilize. In the absence of fossils, which of the following is a method that can be used to determine how nematode species are related to each other?

A. The phylogenetic relationship of known predators of nematodes can be used to infer relatedness of the nematodes.
B. Fossilized burrows or other traces that ancient nematodes left in the environment can be used to reconstruct their relationships.
C. The DNA sequence of currently living nematodes can be used to infer common ancestry and relatedness.
D. Identification of extinct

nematodes can illustrate the relatedness of living nematodes.

Use the following figure to answer question 4.

1. Which tree represents the same evolutionary relationships as the tree shown in the figure?

A. a

B. b

C. c

D. d

Use the following character matrix to answer question 5.

	Trait 1	Trait 2	Trait 3	Trait 4	Trait 5
Species J			+		
Species K			+		
Species L			+		
Species M			+		
Species N			+		

1. Which tree in the figure correctly represents the phylogenetic relationship that would be inferred from the character matrix?

A. a

B. b

C. c

D. d

2. Which of the following modes of natural selection is most likely to increase variability within a population?

A. Directional selection

B. Disruptive selection

C. Random mating selection

D. Stabilizing (or purifying)

selection

Use the following information to answer questions 7 and 8.

A student grew tomatoes in a backyard garden for 10 consecutive years. Different sections of the garden retain water differently in the soil and have different exposure to sunlight. In the first year, the student started the garden from a packet of genetically true-breeding seeds purchased from a local store. Every year, the student counted how many tomatoes were produced by each plant in the garden. The student collected seeds from the plant that produced the most fruit and used those seeds to plant the garden the

following year. The student plotted the average number of tomatoes per plant each year and obtained the following graph. Error bars are calculated as ±1 standard deviation on either side of the mean.

1. What is the most likely reason the average number of tomatoes is not greater in the tenth year than it is in the first?

   A. It is not possible to increase the number of tomatoes by artificial selection.
   B. The tomato plants became inbred and unhealthy during the 10-year period.

C. There is no heritable variation for tomato number.
D. New negative mutations arose and eliminated the effects of artificial selection.

2. What is the mostly likely explanation for the large number of tomatoes harvested in year 4?

A. The environmental conditions were very good for tomato production in year 4.
B. Artificial selection reached peak efficiency in year 4.
C. A beneficial mutation went to fixation in year 4.
D. Genetic variation was highest in year 4.

3. Why are molecular clocks valuable for interpreting phylogenetic trees?

   A. They can be used to demonstrate divergence from species that have not been sampled.
   B. They can be used to measure differences in protein or DNA sequences used to construct a tree.
   C. They can be used to estimate the age of the common ancestor of two species.
   D. They can be used to determine the age of fossils.

Use the following information to answer questions 10 and 11.

White campion (*Silene latifolia*) is a flowering plant whose species range is distributed throughout Europe, western Asia, and northern Africa. Wild populations of *S. latifolia* are sometimes infected by a fungal pathogen called anther smut (*Microbotryum lychnidid-dioiciae*). A team of researchers collected seeds from a population of white campion in Germany and another population in Hungary. The two populations are more than 1000 kilometers apart and the researchers demonstrated that they are genetically distinct. The researchers additionally collected spores of anther smut in Germany and Hungary and demonstrated that they also are genetically distinct.

In the laboratory, the researchers grew white campion from the seeds collected at each location. They then inoculated each plant with anther smut spores either collected from the same population or collected from the opposite population and measured the proportion of plants that became infected. The data that the researchers obtained are shown in the table.

	Origin of anther smut	
Origin of white campion	Germany	Hungary
Germany	0.85	0.68
Hungary	0.78	0.69

Proportion of White Campion Plants That Became Infected by Anther Smut Fungus

1. Which graph in the figure most accurately represents the data shown in the table?

A. a

B. b

C. c

D. d

2. Which of the following statements provides the most

likely explanation for the data shown in the table?

A. The anther smut is highly adapted to the plant genotypes it encounters most.
B. The white campion and the anther smut do not coevolve because the populations are geographically far apart.
C. Genetic diversity is higher in anther smut than it is in white campion.
D. The white campion evolves resistance to local anther smut genotypes.

Use the following information to answer questions 12–14.

Aedes aegypti mosquitoes transmit viruses that cause human diseases like dengue and yellow fever. In order to control disease, widespread use of insecticides is often used to kill mosquito populations. Some *A. aegypti* populations contain mutations that give resistance to commonly used insecticides. Resistance is usually partially dominant, such that *RR* genotypes are completely resistant to the insecticide, "±" genotypes are partially resistant, and *SS* genotypes are completely susceptible. A team of researchers collected *A. aegypti* from Veracruz, Mexico, in 2007 and measured the frequencies of resistant genotypes. The researchers returned to Veracruz in 2009 and again

determined the frequencies of resistant genotypes in the *A. aegypti* population. The data they obtained are shown in the table.

	RR	*RS*	*SS*
2007		45	55
2009		26	26

Data from https://bioone.org/journals/Journal-of-the-American-Mosquito-Control-Association/volume-27/issue-4/11-6149.1/Update-On-the-Frequency-of-Ile1016-Mutation-In-Voltage-Gated/10.2987/11-6149.1.short

Number of *A. aegypti* Mosquitoes with Each Genotype Collected in 2007 and 2009

1. What is the frequency of the *R* allele in 2007?

   A. 0.17

   B. 0.25

   C. 0.42

D. 0.5

2. What is the difference in the frequency of the *SS* genotype between 2007 and 2009?

   A. 0.13
   B. 0.22
   C. 0.25
   D. 0.27

3. What would be the expected number of *RS* heterozygotes if the population were in Hardy–Weinberg equilibrium in 2009?

   A. 37
   B. 49
   C. 51
   D. 62

4. If researchers used a statistical test to determine whether the *A. aegypti* population is in Hardy–Weinberg equilibrium in 2009, would they see any evidence that the assumptions of Hardy–Weinberg equilibrium were violated in 2009?

   A. Yes, because the observed genotype frequencies do not match the expected genotype frequencies
   B. No, because the departure from Hardy–Weinberg expectations is not statistically significant
   C. Yes, because a chi-squared test gives a *P*-value smaller than 0.5
   D. Yes, because natural selection

changed the frequency of the *R* allele between 2007 and 2009

Section 2: Free-Response Questions

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

1. Caribbean islands are home to diverse species of lizards in the genus *Anolis*. Distinct *Anolis* species occupy different habitats on each island. Three common habitats for *Anolis* on each island are treetops, thin tree branches (twigs), and the ground. *Anolis*

species on every island show similar morphological adaptations to these environments, as shown in the table. Using DNA sequence to determine the phylogenetic relationships among *Anolis* species results in the tree shown in the figure. *Leiocephalus barahonensis* is a distant relative to *Anolis*.

Species name	Island	Habitat	Lizard color	Lizard size	Adaptation
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible] and long toes
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible] pads, sticky feet
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible] pads, sticky feet
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible] and long toes
[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible] pads, sticky feet

a. **Identify** the role of *Leiocephalus barahonensis* in the figure.
b. No competing species of lizard are believed to have lived on any of the islands before they were colonized by *Anolis*. The colonization of each island by *Anolis* has been called an adaptive radiation. **Define** adaptive radiation and **describe** how adaptive radiations result in phenotypic diversity.
c. Is the adaptive radiation of

Anolis lizards an example of evolutionary gradualism or punctuated equilibrium? **Provide reasoning** to explain your response.

d. **Identify** a trait that you can claim evolved convergently in two species of *Anolis*. Provide evidence to **support** your claim.

2. The European chiffchaff (*Phylloscopus collybita abientinus*) and the Siberian chiffchaff (*Phylloscopus tristis*) are two species of songbird. The species formed during the Pleistocene ice age when the geographic range of their ancestral species was fragmented by glaciers. The

currently known species diverged from each other during the ice age, but have recently reestablished contact with each other in a small geographic range (known as a hybrid zone) since the glaciers melted at the end of the ice age. European chiffchaff and Siberian chiffchaff have evolved differences in their mating songs, and each species prefers to mate with members of its own species. However, occasionally members of opposite species will mate with each other in the hybrid zone. The offspring of these matings have lower fitness than either pure species.

Scientists collected DNA samples

from birds in the hybrid zone. They also collected DNA from birds in the native range of each pure species. The data from a representative genetic polymorphism are shown in the table.

	European chiffchaff range	Hybrid zone	Siberian chiffchaff range
AA	40	10	
Aa	0	0	
aa	20	40	

Genotypes Obtained from Chiffchaff Birds in Three Geographic Regions

a. **Identify** the speciation process that led to the separation of European chiffchaff and

Siberian chiffchaff.

b. Based on the information provided, is there prezygotic isolation between European chiffchaff and Siberian chiffchaff? Is there postzygotic isolation between European chiffchaff and Siberian chiffchaff? **Justify** your responses.

c. Based on the data provided in the table, is the population in the hybrid zone in Hardy–Weinberg equilibrium? Use a statistical test to **evaluate** the null hypothesis.

d. A scientist makes a claim that European chiffchaff females would have increased fitness

from a mutation that made them more willing to mate with Siberian chiffchaff males because they would have more reproductive opportunity. **Provide reasoning** to support or refute the scientist's claim.

Unit 8

Ecology

Module 51

Responses to the Environment

Unit	51	52	53	54	55	56	57

LEARNING GOALS

- **LG 51.1 Ecological systems are organized in a hierarchy that starts with individuals.**
- **LG 51.2 Individuals adjust their physiology and behavior in response to environmental changes.**
- **LG 51.3 Individuals use communication to improve fitness.**
- **LG 51.4 Individual responses to the environment are vital to natural**

selection.

As we have proceeded through the units of this book, we have examined a wide range of topics including molecules, cells, cell cycles, genes, and gene expression. We have also examined the processes of heredity and evolution. With this understanding, we are now prepared to move to higher levels of complexity, ranging from individual organisms all way up to the entire biosphere of Earth. This is the realm of ecology, which examines how the adaptations of species help them survive and reproduce in the context of interactions with other species and the nonliving world. We will begin

this journey by examining the different levels of ecology. We will then focus on the physiological and behavioral responses of individuals that help them improve their fitness. We will then discuss how individuals use communication to further improve their survival and reproduction, and how innate and learned behaviors represent critical adaptations that have been favored by natural selection.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

EVOLUTION: Look for relationships between the way an organism

responds to its environment and its ability to survive and achieve reproductive success.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

51.1 Ecological systems are organized in a hierarchy that starts with individuals

When we examine the ecology of the natural world, we find it helpful to categorize the world into a hierarchy of levels: individuals, populations, communities, ecosystems, and the biosphere. You can see these different levels in **FIGURE 51.1**. As we will see in this section, moving from individual organisms to the entire

biosphere, each level is a subset of the next higher level, such that they exist in a hierarchy.

FIGURE 51.1 The hierarchy of ecological systems

At the lowest level, an individual, ecologists focus on the adaptations that improve survival and reproduction. The next level is a population, which is a group of individuals that experience changes in abundance and is the focus of evolutionary changes. The third level is a community, which is a collection of species in an area that interact with each other. The next higher level is an ecosystem, which combines the living and nonliving world with a focus on how energy and matter move throughout the

system. Finally, we have the biosphere, which includes all ecosystems on Earth.

Individuals

The individual is the smallest and most fundamental unit in the ecological hierarchy. While there are lower biological levels including organs, cells, and molecules, the individual is the first level that can live on its own in the environment. At the individual level, we focus on examining the adaptations that allow organisms to optimize their survival and reproduction. For example, you might recall the story of the Canada lynx and snowshoe hare at the

beginning of the book. At the individual level, biologists focus on the physiological, morphological, and behavioral adaptations that help the lynx evolve to be a better predator and the hare evolve to avoid being killed by the lynx.

Populations

A population consists of all individuals belonging to the same species within a given area. The area may include every individual of the species, such as an entire continent, or it may be delineated to be much smaller, such as the number of squirrels of a given species within Pennsylvania or the number of catfish

in a pond.

One challenge in defining a population is the ability to first define a species. As discussed in Module 47, biologists have historically defined a species as a group of individuals that naturally breed and produce fertile offspring. Over time, we have realized that some species do not fit this definition. For example, some species of salamanders consist of only female individuals that—without any breeding—produce only daughters. In addition, we now know that bacteria exchange genetic material with other very distantly related bacteria. Thus, there is no single definition of species that works for all organisms.

However, the historic definition continues to work well for many species of plants and animals.

AP® EXAM TIP

PREP FOR THE AP® EXAM

Remember that evolution works at the level of populations, not individuals; populations evolve, and individuals within a population are selected by evolution.

Communities

Moving up the ecological hierarchy, a community is a collection of populations in a given area that interact with each other. These interactions include predators eating

prey, pollinators fertilizing flowers, and plants competing with each other for nutrients. Similar to a population, the boundaries of a community can vary a great deal. For example, we may want to examine the community of species living in a city park or at the top of a mountain.

Ecosystems

Ecosystems are comprised of multiple communities as well as the nonliving physical and chemical environments, including sunlight, water, and temperature. For instance, we might examine the Great Lakes ecosystem that includes eight midwestern U.S. states and the province of Ontario, or

the Greater Yellowstone ecosystem, which spans parts of Wyoming, Montana, and Idaho. At the ecosystem level, we are primarily interested in the movement of energy and elements, such as carbon, nitrogen, and phosphorus, which make up a large proportion of the elements needed for living organisms.

Biosphere

The highest ecological level is the biosphere, which includes all ecosystems on Earth. At this level, we focus on the movement of matter and energy by air currents, water currents, and the long-distance

migration of organisms. Within the biosphere, nutrients cycle within and between the ecosystems, whereas energy is primarily provided by the sun and some fraction of the energy leaves Earth and is lost to space.

The Importance of Physical Principles

For each level of ecology, it is helpful to remember that the level is governed by physical principles. One important physical principle is the law of conservation of matter, discussed in Unit 3. As you will recall, the law of conservation of matter states that matter is not created or destroyed, but it can change form. We

will see an example of this later in this unit when we examine how important elements such as carbon and nitrogen cycle through ecosystems in different forms. The second physical principle is the law of conservation of energy, which states that energy cannot be created or destroyed, but it can be converted into different forms. Taken together, these physical principles tell us that we should be able to track the movement of elements and energy at each level in the hierarchy. We will see many examples of that principle throughout this unit.

✓ Concept Check

1. **Describe** why populations are

considered a subset of communities in the ecological hierarchy.

2. **Describe** the levels of communities and ecosystems.

3. **Describe** how physical principles help us track the movement of matter and energy in ecological systems.

51.2 Individuals adjust their physiology and behavior in response to environmental changes

At the individual level, ecologists focus on the adaptations that individuals possess as a result of natural selection. As we saw in the discussion of phenotypic plasticity in Module 29, a wide variety of organisms can detect changes in their environment and respond by altering

the phenotypes, including changes in their physiology and behavior. In this section, we will examine some other fascinating examples of how organisms make these adjustments in response to changes in their environment. These changes include individuals orienting toward or away from environmental stimuli, individuals navigating over long distances, and individuals possessing a biological clock. In each case, we will see how possessing physiological and behavioral responses improves individual performance and increases their fitness, suggesting that these responses are the product of natural selection.

Orientation Toward and Away From Environmental Stimuli

Organisms can respond to the environment by moving toward favorable stimuli and moving away from unfavorable stimuli. For example, bacteria and protozoa that experience water that is too warm or too salty increase their movement speed and start turning in random directions. This type of random movement is known as kinesis. Once they encounter more favorable conditions, they reduce their speed and reduce their turning rate. In

other organisms, the movement is not random but in a specific direction, such as a gazelle walking toward a field of grass or running away from a predator. This movement in a specific direction is known as taxis (pronounced *tak-ses*). In all of these cases, moving toward favorable stimuli and away from unfavorable stimuli results in the organism experiencing more favorable conditions, resulting in greater evolutionary fitness.

A common type of taxis is the movement of plants in response to the direction of sunlight. If you have ever grown houseplants near a window, you may have noticed that

over a time span of several weeks the plant grows toward the window where the sunlight is the strongest. This process, known as phototropism, occurs because plants possess hormones in the tips of their stems, as shown in **FIGURE 51.2**. For phototropism, an important group of plant hormones is called auxins. If the stem tip receives sunlight from above, so that both sides of the stem tip are in the sun, the stem tip sends auxins down both sides of the stem and the plant grows straight up toward the light. However, if the stem tip receives sunlight on only one side, it sends auxins down the shady side of the stem. As auxins build up in concentration, they cause the cells of

the stem to elongate on the shady side of the stem, which causes the stem to slowly bend toward the light. As a result, the plant can bend toward the light and increase the rate of photosynthesis to make more sugars that are essential for the plant's growth and reproduction.

FIGURE 51.2 Phototropism in plants

Plants can respond to the direction of incoming sunlight by bending their stems toward the source of the light. (a) When the light is straight above the plant, the plant sends a hormone, known as auxin, down both sides of the stem and the stem does not bend. (b) When the light strikes the plant from one side, the plant sends auxin to the shady

side of the stem. This causes cells on the shady side to elongate, which causes the stem to bend toward the source of the light.

Plants can also respond to day length in ways that help the plant properly time when to flower and make seeds to ensure optimal fitness. The number of sunlit hours of the day, known as the photoperiod, can have different effects on different species of plants. Some species of plants, such as potatoes and spinach, only flower in the summer when days are the longest, so we refer to them as long-day plants. Other plants, such as the poinsettia and Christmas cactus,

only flower in the winter when days are the shortest, so we refer to them as short-day plants. Finally, some plants such as tomatoes and corn, are not affected by day length, so we refer to them as day-neutral plants. The plant can determine day length using photoreceptors in its leaves that cause an accumulation of a protein. When night arrives, the protein is degraded. In the case of long-day plants, as the days get longer from spring to summer, the amount of protein produced each day becomes greater until it reaches a threshold amount that triggers the plant buds to make flowers. These adaptations to day length help ensure that plant species reproduce at the time of year that will

give them the best conditions for survival and reproduction, including opportunities for pollination, the appropriate temperature and amount of sunlight, and the necessary water availability to make their seeds.

Photoperiods are also very important to animals. For example, migrating birds in the Northern Hemisphere use photoperiods to know when to migrate north and start breeding, and when to fly south as winter approaches. Mammals also rely on photoperiods to stimulate the production of hormones that lead to breeding behavior. For example, white-tailed deer breed in the fall and then give birth in the late spring

when there is abundant food available for their fawns. In all these cases, responding to the photoperiod helps plants and animals time their behavior and physiology to increase their fitness.

Navigation

Some species need to orient themselves for very long distances, and they have evolved methods of navigation. A classic example of navigation occurs in the homing pigeon, which can travel hundreds of kilometers away from home and then needs to find its way back. The bird has evolved to use a combination of cues, including being able to navigate

based on star patterns at night and having the ability to detect magnetic north, much like a compass. In fact, when researchers attached a magnet to the heads of homing pigeons, the birds could no longer navigate home because it interfered with their internal compass. Such experiments have confirmed that the homing pigeon possesses an internal compass in its head that helps it to navigate.

Biological Clocks

Animals also respond to the presence of daylight and darkness. For instance, the retinas in the eyes of vertebrates sense daylight and darkness and they communicate this

information to the pineal gland in the brain. Some species of fish and reptiles have specialized photosensitive cells on the skull between the eyes that detect a light versus dark environment, as you can see in **FIGURE 51.3**. In both situations, when the animal experiences darkness, the pineal gland releases a hormone known as melatonin. What is particularly fascinating is that nocturnal animals (those active at night) and diurnal animals (those active during the day) respond differently to increases in melatonin. In nocturnal animals, increased melatonin causes the animals to become active. In diurnal animals, however, increased

melatonin causes the animals to sleep.

FIGURE 51.3 A third eye

Some species of lizards and fish, such as this tuatara (*Sphenodon punctatus*), have a region of photosensitive cells located between the two eyes that are used to detect light.

These natural cycles of daylight and darkness help set a circadian clock, which is an approximately 24-hour clock in organisms that regulates a wide range of activities including when to sleep, when to eat, and when to release specific hormones. Circadian clocks are common in all groups of organisms including animals, plants, fungi, and bacteria.

The clocks work by having a group of "clock genes" that turn on and off in feedback loops on a 24-hour cycle. In fact, many species, including humans, continue to experience the same circadian clock of activities if they are put in an environment having 24 hours of darkness. By knowing what time of day it is, organisms can adjust their physiology and behavior to improve their performance and increase their fitness. For example, some species of algae can migrate up to shallow water at sunrise to obtain the more abundant sunlight and then migrate down to deeper water at sunset to obtain more abundant nutrients.

✓ Concept Check

51.3 Individuals use

communication to improve fitness

When individuals determine the best behavioral response to their environment, they improve their performance, which improves their evolutionary fitness. Individuals can gain a substantial amount of information about the best response from others around them. This can include individuals of the same species or different species, such as prey responding to predators. In considering communication, we can think about a sender of information and a receiver of information. We can then define communication as a transfer of information between two individuals. In this section, we will

explore the many different ways that animals communicate including visual, auditory, chemical, tactile, and electrical signals.

Visual Communication

Visual signals are signals that can be seen by another individual. For example, in the northern cardinal (*Cardinalis cardinalis*), a common bird in North America, the male cardinal has bright red feathers while the female has feathers that are quite drab, as shown in **FIGURE 51.4**. The male's bright red feathers are a visual signal to females that the bird is a male. The male's red color is also

more intense when he consumes a high-quality diet. Thus, intensely red feathers can serve as a signal to females that the male is a high-quality mate. At the same time, the drab feathers of the female cardinal are a signal to the male that the bird is a potential mating partner. Other visual signals include antlers on male deer, brightly colored flowers to attract pollinating bees, and the elaborate courtship dances that some bird species perform to attract a mate.

FIGURE 51.4 Visual signals

In the northern cardinal, the male on the left has bright red feathers that signal the cardinal is a male and that he has been eating a high-quality diet. The

female on the right is much drabber, which helps to communicate that she is a female.

Auditory Communication

Auditory signals can also communicate information. Some auditory signals communicate an impending danger, such as the rattling tail of a rattlesnake when it feels threatened. Auditory signals can also be used to attract mates, such as the songs of breeding birds and frogs. Animals also use calls to warn other members of their species when a predator is approaching. For example, the vervet monkey

(*Chlorocebus pygerythrus*) gives unique warning calls depending on the situation. It uses one call to communicate to its relatives that a predator such as a hawk is approaching from the sky and a different call if a predator such as a leopard or snake is approaching from the ground. Such warning signals can induce a wide range of responses, such as hiding or the forming of aggregations, including herds of mammals, schools of fish, and flocks of birds.

Chemical Communication

Chemical signals are also important

in communication. Some chemicals are used to attract mates. By releasing chemicals into the air, an animal can advertise over a large area that it is ready to mate. For example, female dogs and cats release chemicals that communicate that they are in heat and ready to mate. Chemicals can also be dropped along a food trail by insects such as ants to help communicate the path from the ant nest to a source of food. Chemicals can also be used to warn others about the presence of predators. For instance, many species of fish have specialized skin cells that release a chemical into the water whenever the fish is attacked by a predator. When other fish smell the chemical in the

water, they may hide and become less active to reduce their risk of being detected by the predator. Finally, chemicals can be used to mark the boundaries of animal territories to warn other members of a species to stay away from another individual's territory or risk being attacked by the territory owner.

Many plants also use chemical communication. For example, consider the goldenrod plants that are found in abandoned farm fields throughout the eastern United States. When these plants are attacked by a beetle that chews on its leaves, the leaves release a chemical into the air that neighboring plants can detect.

When they detect the chemical in the air, the neighboring plants begin producing anti-herbivore chemicals in their leaves to defend themselves against being eaten by the beetles if they arrive.

Other species of flowering plants emit odors that help attract pollinators in addition to any visual cues, such as flower color. In some cases, as illustrated by the "corpse flower" in **FIGURE 51.5**, the smell is not at all pleasant. This plant, officially known as the titan arum (*Amorphophallus titanum*), is pollinated by flies that feed on dead animals. To attract these flies to pollinate the plant, the flower releases a chemical that smells like a

rotting corpse.

FIGURE 51.5 Chemical signals in plants

The titan arum, also known as the corpse flower, releases chemicals that smell like a decomposing animal. This odor attracts flies that it needs for pollination. When not pollinating the flower, the flies feed on dead animals.

Tactile and Electrical Communication

Perhaps less obvious are tactile and electrical signals in communication. In tactile communication, organisms respond to a stimulus through the sense of touch. For example, the

vibrations in a spider web, caused by a struggling prey, communicate to the spider that is standing elsewhere on the web that a meal has just arrived. In amphibians, species such as the white-lipped frog (*Leptodactylus albilabris*) make a breeding call while their body is pressed against the ground and this causes a vibration through the ground that attracts female frogs. Similarly, some insects that feed on plant leaves can send vibrations through the leaves to communicate with other insects of the same species. Electrical communication is less common, although there are species of fish, such as the brown ghost knifefish (*Apteronotus leptorhynchus*), that send

weak electrical signals through the water to communicate with each other, including information on the sex of the fish that is sending out the signal.

✓ Concept Check

7. **Describe** why animals responding to day length would not be an example of communication.

8. **Describe** how warning calls could improve the fitness of the individual that makes the call.

9. **Describe** how the predator-specific warning calls of the vervet monkey are more beneficial to other members of its species than a more generalized predator call.

51.4 Individual responses to the environment are vital to natural selection

We have already seen examples of

physiological and behavioral responses that include avoiding predators and herbivores, finding food, locating a mate, and attracting pollinators. Given that these responses can have major impacts on an individual's survival and reproduction, you can appreciate that responses to environmental changes and responses to communication have important consequences for fitness. In this section, we continue to explore behavioral responses to the environment by examining how both innate and learned behaviors can be favored by natural selection and the importance of cooperative behaviors on improving the fitness of individuals.

Innate Behaviors

As we saw in Module 29, all phenotypes are the product of the genes that an individual carries and the environments that an individual experiences. When it comes to understanding any phenotype, such as a specific behavior, biologists have come to appreciate that there are **innate behaviors**, also known as instinctive behaviors, which means that the behavior is performed without any previous experience. Innate behavior is largely determined by genes, with a much smaller effect of the individual's environment. In contrast, there are **learned behaviors**, which means while the

genes are necessary to perform the behavior, the individual's experience in its environment plays a large role in determining the behavior.

As you might expect, innate behaviors are very similar among individuals of the same species. In many bird species, for example, there are elaborate courtship displays that males perform to impress females in an effort to convince the females to mate, as shown in **FIGURE 51.6**. These displays commonly involve the male puffing up his feathers to appear large, flapping his wings in a particular way, and walking or flying around the female to get her attention. Courtship behaviors such

as these are innate. In some birds, researchers have discovered that a male held in isolation his whole life is still capable of producing a perfect courtship display for females. Providing a proper courtship dance at the first mating opportunity would be of great value to the male bird since it would increase his probability of reproducing and increasing his fitness.

FIGURE 51.6 Innate courtship behavior

In the Raggiana bird-of-paradise (*Paradisaea raggiana*), the male (top) exhibits courtship behaviors that are innate, including puffing up his tail feathers and outstretching his wings in

an attempt to convince the female (bottom) to breed.

Learned Behaviors

Learned behaviors are also common in a wide variety of animals, where the learning leads to improved fitness. One form of learning is through the process of habituation, in which animals learn over time to ignore a stimulus. For example, if you place a scarecrow in a garden, the crows are initially scared away by the human-like shape. After a few days, however, the crows learn that the scarecrow is not an actual human and poses no real risk, so they begin to fly

back into the garden, as shown in **FIGURE 51.7**. This learning process allows the crows to capitalize on a food source.

FIGURE 51.7 Habituation

Habituation is a learned behavior. Scarecrows are designed to scare away crows and other birds by appearing to be a human. Over time, however, the birds learn that the scarecrow is not a real human, so they return to the area to feed on the crops.

Another form of learning is operant conditioning, in which an animal is either rewarded or punished after a behavior. Rats, for example, are unable to vomit, so they are very hesitant to try new foods. When they

find a new food, they sample a very small bite and then wait to see if it makes them sick. If the new food does make them sick, then they have been careful to only have consumed a small amount. If it does not, they will eat more of the new food the next time they find it. By using this learning process, rats minimize harm from bad foods while being open to learning about new foods that could improve their growth, survival, and reproduction.

A third fascinating type of learning is imitation, which occurs when individuals learn a behavior from watching other individuals perform. For example, in years past, people in

Britain had milk delivered to their doorsteps in the form of glass bottles with foil lids. At some point, a bird learned that it could peck at the lid, make an opening in the foil, and access the cream at the top of the milk jar, shown in **FIGURE 51.8**. By observing this single bird's behavior and imitating it, the behavior spread rapidly across several species of birds in Britain. The ability to learn by imitation provided an entirely new food source for the birds, demonstrating that imitation has fitness advantages.

FIGURE 51.8 Learning by imitation

In Britain, milk used to be delivered with a foil cap. Researchers discovered that

once one bird learned to pierce the foil to consume the cream at the top of the milk bottle, such as this English blue tit (*Cyanistes caeruleus*), other birds observed this behavior and learned to imitate it.

Another important behavior is imprinting, which commonly occurs when animals are young, and they learn what their parents look like. In a series of classic experiments, researchers discovered that bird offspring that quickly leave their nest after hatching fix on the first animal they see as a parent. This makes sense from an evolutionary perspective because the vast majority of the time the first animal a

hatchling bird sees is indeed its parent, and knowing who to follow is critical for the hatchling to be fed and protected. However, the researchers discovered that if a human is the first animal seen by the hatchlings, the hatchlings follow the human everywhere as if it is the parent. **FIGURE 51.9** shows a particularly well-known example. In fact, the hatchlings continued to follow their human "parent" even when they were later presented with their real mother. Thus, there are many ways for animals to learn and it might be tempting to think that only larger animals, such as birds and mammals, are intelligent enough to learn. However, as you will see in Practicing

Science 51.1, "To what extent are insects capable of learning?" even small insects are capable of learning, and doing so has tremendous fitness benefits.

FIGURE 51.9 Learning by imprinting

In a classic experiment, researcher Konrad Lorenz made himself the first animal that would be seen by hatchling ducks. Throughout their life, the ducks would follow him as if he were their mother.

Practicing Science 51.1

To what extent are insects capable of learning?

PREP FOR THE AP® EXAM

Background European digger wasps (*Philanthus triangulum*) live in burrows in the sand and they hunt honeybees to feed their developing young. After mating, each female wasp digs a long burrow with a few chambers at the end where she lays her eggs. She then forages for honeybees that she brings back to these chambers for her larvae to eat. The wasp faces a navigational challenge: having captured her prey, how can she find her way back to her nest? An early researcher of animal behavior, Niko Tinbergen, noticed that wasps lingered briefly near their nest before heading off to hunt. He hypothesized that they were learning local landmarks associated with the nest.

Hypothesis Wasps learn visual cues

around their nests to help locate the nest upon their return.

Method Tinbergen recognized that a good test of the learning abilities of an insect should take place in its natural environment. He devised an elegant demonstration of the way in which female wasps learn landmarks for navigation. He placed a ring of pine cones around the nest of a wasp, as shown in the first figure following. Once she had left to hunt, he shifted them to a new location away from the nest entrance, as shown in the second figure. For other nests, he placed a pine cone ring around the nest of a wasp and the ring was not shifted away after the wasp left to hunt. If visual cues are key to the wasp's ability to locate the nest, all of the wasps should return to the pine cone

rings. In contrast, if cues are, for example, olfactory, the wasp should return directly to the nest rather than the pine cone rings.

Results Female digger wasps carried out a brief landmark-learning flight on departure from the nest. When the landmarks were moved, the females returned to the wrong location.

Conclusion Female digger wasps learn and use visual landmarks, such as the experimental ring of pine cones, as cues to the nest location.

AP® PRACTICE QUESTION

a. **Identify** the following:

1. The question being investigated by the experimenters
2. The hypothesis they tested
3. The experimental group
4. The control group
5. The independent variable
6. The dependent variable

b. **Explain** the results of the experiment by **identifying** the researchers' claim and **justifying** the claim with the evidence and the reasoning researchers used (CER).

Cooperative Behaviors

Some animal species are very social with one another and show high

levels of **cooperative behavior**, in which members of the same species exhibit behaviors that improve another individual's fitness. Being social with other members of a species has a number of large fitness advantages. For example, spending time in groups results in more eyes searching for food and looking out for predators. It also allows prey to use group defense against predators, such as when muskox (*Ovibos moschatus*) form an outward facing circle of adults to protect the vulnerable calves, as shown in **FIGURE 51.10**. Among predators, such as wolves and lions, living in groups allows them to hunt down and subdue much larger prey than a single predator could do

alone. Despite these advantages, living in groups also has some disadvantages, including having to share food with others, being more detectable as a group to predators, and being susceptible to the rapid spread of disease due to living close together. When the benefits of cooperative behavior outweigh the costs, a species should be favored by evolution to exhibit cooperative behavior.

FIGURE 51.10 Benefits of cooperative social behavior

When a muskox herd is threatened by predators, the adults form a circle with their horns facing outward. The vulnerable young muskox are placed in a

protective position in the middle of the circle.

Some species take cooperative behavior to the extreme by living in groups with very large numbers, with only one or a few individuals doing the breeding. For example, many species of bees, wasps, and ants live in groups ranging from hundreds to tens of thousands. In a hive of honeybees, there is typically one queen who lays all the eggs. She lays thousands of eggs that are diploid and develop into daughters, which are also known as the workers. These workers build the honeycomb, fly out to flowers to collect nectar and pollen, convert the nectar into honey

back at the hive, and raise the next generation of offspring. Only occasionally does the queen bee lay haploid eggs, which develop into sons. The sons are not workers, but instead leave the hive to fertilize other queens, thereby increasing the fitness of the queen bee. Such highly social groups have evolved because of the large benefit of working together and the low probability of any single individual being able to survive and reproduce on its own.

Review Questions

1. Which is the correct order of hierarchy for the level of ecology, from the simplest to the most complex?

A. Individual, population, community, ecosystem, biosphere
B. Individual, community, population, ecosystem, biosphere
C. Population, individual, community, ecosystem, biosphere
D. Population, individual, ecosystem, community, biosphere

2. Which statement about responses to environmental stimuli is true?

A. Short-day plants flower when there is a long photoperiod.
B. Plants experiencing phototropism move toward sunlight.
C. Navigating birds lack an internal compass, so they rely on stars.
D. A circadian clock operates during daylight hours.

3. Which statement about communication is false?

A. Brightly colored flowers communicate a source of nectar to pollinators.
B. Rattlesnakes use auditory communication when threatened.

C. Animals mark their territories using chemical communication.
D. Plants are unable to use chemical communication.

4. Which statement is true about innate or learned behaviors?

A. Innate behaviors are performed better over time.
B. Imprinting on a parent is an example of an innate behavior.
C. Imitation is an example of a learned behavior.
D. Courtship displays in birds are commonly learned behaviors.

5. Which statement about social behavior is false?

A. The fitness costs of social living outweigh the fitness benefits.
B. Benefits include the ability of predators to capture and subdue large prey.
C. Costs include having to share food with other members of the same species.
D. Some species are highly social, living in groups that number in the thousands.

Module 51 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice

Questions

Choose the best answer for questions 1–4.

1. Scientists observed that a population of bacteria growing in a flask of liquid medium do not distribute evenly throughout the medium if there is a magnet on one side of the flask. Instead, the bacteria tend to cluster close to the magnet. Which best describes the behavior exhibited by the bacteria?

   A. The bacteria are responding to their biological clocks.
   B. The bacteria are communicating to coordinate

their movement.

C. The bacteria are exhibiting taxis.

D. The bacteria are exhibiting kinesis.

Questions 2 and 3 refer to the following information.

Students conduct an experiment with a population of bacteria named *Alcaligenes faecalis*. These bacteria move by using a tail-like structure called a flagellum. The students place two groups of bacteria into two beakers containing the same medium. The students place a capillary tube containing water into the first beaker, and they place a capillary tube filled with glucose

dissolved in water into the second tube. Both the water and the glucose can diffuse out of the capillary tubes and into the medium in the beakers. The students observe the movements of the bacteria in both beakers. After a period of time, the students record the location of the bacteria in the beakers, which are represented as the white dots in the figure.

1. Identify the independent variable in the experiment.

   A. The presence of glucose
   B. The presence of *Alcaligenes faecalis*
   C. The presence of the water-

containing capillary tube

D. The presence of the medium into which *Alcaligenes faecalis* are placed

2. Which best describes the movement of the bacteria in the beaker with glucose?

   A. Taxis
   B. Kinesis
   C. Navigation
   D. Directed movement

3. Rattlesnakes rattle their tails to ward off potential predators. The rattling sound communicates to other animals that the rattlesnake is poisonous and will retaliate if attacked. In recent decades,

ecologists in the western United States have observed an increase in the percentage of the rattlesnake population that is unable to make any rattling sound. Researchers also observed an increase in humans finding and killing rattlesnakes in the same region during the same time. Which best explains why the rattlesnake population is increasingly unable to make a rattling sound?

A. Rattlesnakes that rattle their tails have an increased fitness because they are less likely to be found by animals that are hunting them.
B. Rattlesnakes that do not rattle

their tails have a decreased fitness because they cannot scare off humans that are hunting them.

C. Rattlesnakes that do not rattle their tails have an increased fitness because they are less likely to be heard by humans hunting them.

D. Rattlesnakes that rattle their tails have an increased fitness because they scare off humans that are hunting them.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples.

Where calculations are required, show your work.

A group of scientists conducted an experiment to study how a type of fish called the stickleback fish behave in response to seeing brine shrimp, which are a food source for the fish. The scientists placed 35 shrimp in a clear glass tube and then put the tube into the middle of an aquarium containing one stickleback fish. The glass tube prevented the shrimp from being eaten by the fish. The data presented in the figure were collected from observing how many times, over a period of 10 minutes, the fish bit at the glass tube in an attempt to eat the shrimp. The number of attempts each

fish made were averaged and plotted on the graph. Error bars are calculated as ±1 standard error on either side of the mean.

Data from Bell, A. M., and H. V. S. Peeke. 2012. Individual variation in habituation: behavior over time toward different stimuli in threespine sticklebacks (*Gasterosteus aculeatus*). *Behaviour* 149:1339–1365.

a. **Identify** the type of behavior, including whether the behavior is innate or learned, that the fish displayed over the 10 minutes of the experiment. **Justify** your answer.
b. **Describe** how this kind of

behavior benefits the stickleback fish.

c. In a separate fish tank that is used to maintain the stickleback colony and not subjected to the experimental conditions, the researcher feeds the fish every day by putting food into the water at the rear of the tank. The researcher notices that as soon as the lid of the tank is lifted, the fish move to the rear of the tank. One day, the caretaker feeds the fish by lifting the lid and putting the food into the front of the tank. **Predict** how the fish will respond. **Provide reasoning** for your prediction.

Module 52

Energy Flow through Ecosystems

Unit	51	52	53	54	55	56	57

LEARNING GOALS

- **LG 52.1 There are different strategies for acquiring and using energy.**
- **LG 52.2 Energy is captured and moved through ecosystems.**
- **LG 52.3 Matter cycles in ecosystems.**

In the previous module, we introduced the field of ecology, which

studies a wide range of spheres from individuals, to populations, to communities, and the biosphere. We then focused on the physiological and behavioral responses that allow species to live in specific environmental conditions. We also discussed the different forms of communication individuals use and how natural selection has favored both innate and learned behaviors. With that background, we are now ready to focus on how energy flows through individuals, communities, and ecosystems.

In this module, we will explore how species have evolved to acquire and use energy to fuel their survival,

growth, and reproduction. We will examine the ways in which species use energy to affect their body temperature and how energy needs change with body size. We will also look at how energy availability changes through the seasons, which affects the reproductive strategies of species. We will then consider how energy moves from those species that capture energy to species that obtain their energy by consuming other species. We will also consider the efficiency of moving energy among different groups of organisms to understand how the need for energy limits the number of individuals of different species that can be supported in an ecosystem. Finally,

we will examine how elements cycle in ecosystems, using the cycling of carbon as a key example.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

ENERGETICS: Think about the strategies that organisms employ to capture energy from their environment, and look for examples of strategies that are conserved among related organisms.

52.1 There are different strategies for acquiring and using energy

As we saw in the previous module,

individuals need energy for growth, reproduction, and survival. In this section, we will examine the two strategies that have evolved to regulate energy acquisition and metabolic rate: having a constant body temperature that is internally regulated or having a body temperature that is more strongly affected by the external environment. We will then examine how energy availability and metabolic rate affect growth, survival, and reproductive strategies.

Using Energy to Regulate Body Temperature and

Metabolism

As you may recall from Unit 2, cells maintain stable conditions in a process we call homeostasis. Homeostasis is typically achieved through negative feedback loops using cell signaling molecules that bind to receptors on target cells. Once the cell achieves its set point, the signal is turned off to avoid overcorrecting, which helps the cell maintain steady conditions. Homeostasis happens not only at the level of the cell but also at the level of the entire organism. Maintaining homeostasis allows organisms to grow and reproduce, which both require a particular range of steady

internal conditions. Here we will examine how homeostasis operates at the level of the whole organism, with a focus on how organisms control their body temperature.

The process of an organism controlling its body temperature is known as thermoregulation. In thinking about thermoregulation, we can make a distinction between organisms with two different mechanisms, *endotherms* and *ectotherms*. The body temperature of organisms known as **endotherms** is regulated internally. Well-known endotherms include mammals and birds, which use negative feedback loops to maintain body temperatures

that are typically warmer than their external environment. As described in Unit 4, a negative feedback loop works like a thermostat in a house. When the thermostat detects that the house is colder than desired, it sends a signal to the home's heater and the heater makes more heat. Once the house warms up to the desired temperature, the thermostat stops sending a signal to the home's heater, so the heater stops making heat. In a similar way, when the body of a bird or mammal becomes colder than some internal set point, an organ in the brain known as the hypothalamus sends a signal to make muscles begin shivering to generate heat. When the body becomes warm enough, the

hypothalamus stops sending the signal. (See Figures 20.10 and 20.11.)

Ectotherms are organisms that typically generate relatively small amounts of heat, so their body temperatures are strongly impacted by external conditions. Most plants are ectotherms, although some have fascinating physiological adaptations to internally generate heat. For example, a plant known as skunk cabbage (*Symplocarpus foetidus*) is one of the first plants to emerge in early spring in eastern North America, as illustrated in **FIGURE 52.1**. Even when there is some snow on the ground, the skunk cabbage uses its mitochondria to generate large

amounts of metabolic heat to increase its internal temperature, up to 10°C higher than the air temperature. While generating this heat requires a large amount of energy, the plant benefits by emerging early. It experiences more rapid growth of its flowers, attracts the flies that pollinate it, and protects itself from freezing air temperatures that would kill most plants. Thus, the skunk cabbage's heat generation provides major fitness benefits by allowing it to emerge and make flowers before any competing species of plants can emerge and attract pollinators.

FIGURE 52.1 Skunk cabbage

Skunk cabbage species are an unusual

group of plants which can internally generate heat. Using their mitochondria to generate metabolic heat, the plants can elevate their temperature to be 10°C warmer than the surrounding air temperature and melt their way up through the snow.

For animals that are ectotherms, it is tempting to think that their internal temperature simply reflects the temperature of their external environment. However, the reality is far more fascinating because many species of ectothermic animals can adjust the temperature of their bodies by altering their behavior. For example, scorpions living in a hot desert can avoid lethal overheating by

seeking shade. Alternatively, when the air is cool and ectothermic animals want to increase their body temperature, they can bask in the sun to make their body temperature increase. This basking behavior improves an animal's ability to move, capture food, and digest its food. As a result, this improved performance increases its evolutionary fitness. Such behavioral thermoregulation is very common in species of ectotherms including reptiles, amphibians, and insects.

"**Visual Synthesis 8.1: Homeostasis and Thermoregulation**" provides an overview of homeostasis and thermoregulation. The rock squirrel

(*Otospermophilus variegatus*), an endotherm, can curl up in a burrow during cold nights to reduce heat loss, and contract its muscles rapidly (shiver) to generate heat. It also uses a mechanism known as vasoconstriction, which narrows arteries in its arms and legs. This constriction reduces the amount of blood in the limbs to reduce heat loss. As noted earlier, the hypothalamus acts as the body's thermostat and controls the animal's physiological responses, such as shivering and vasoconstriction.

The motor cortex of the brain controls behavior, such as burrowing behavior and activity level. When the

rock squirrel experiences cold days, it can increase its activity and generate more heat from its muscles. Should it get too hot in the middle of the day, the squirrel alters its physiology by panting, moving very little, and using vasodilation, which increases the flow of blood in the veins and arteries in its limbs to get rid of excess heat. The squirrel also changes its behavior by seeking shade and licking its forelimbs so that the evaporating saliva removes heat from its body.

In contrast, ectotherms such as the zebra-tailed lizard (*Callisaurus draconoides*) rely a great deal on behavioral responses to achieve a desired body temperature. During

cold nights, the lizard's hypothalamus triggers the motor cortex to induce burrowing behavior. During cool mornings, the lizard comes out of the burrow, uses vasodilation to move more blood out to its limbs to gain heat from warm rocks, increases its activity to generate muscle heat, and basks in the sun to gain heat. Should the daytime temperature get too hot, the lizard can adjust by decreasing its activity, seeking shade, and lying on cool rocks and dirt to lower its body temperature. As you may have noticed, these responses to temperature changes are all examples of stimulus and response, which we examined in our discussion of cell communication in Unit 4. Through

these activities, the lizard can have a warmer body temperature, which improves its ability to move, catch prey, and digest its prey—all with the effect of improving its ability to grow and reproduce.

Ecological Strategies in Response to Energy Availability and Energy Needs

When it comes to the evolution of different ecological strategies for growth and reproduction, the issue of energy availability becomes an important factor. This is because a net gain in energy allows an

individual to experience growth and reproduction, which can lead to an increase in the size of a population. In contrast, a net loss of energy results in lost growth and reproduction. If a net loss of energy occurs over extended periods, it can also lead to the death of an individual and a decline in the population.

The energy needs of individual organisms differ depending on whether they are endotherms or ectotherms. We can compare the energy needs of different organisms by measuring their **metabolic rate**, which is the number of calories that an organism burns over time while at rest. Given that endotherms maintain

a constant body temperature that is typically higher than their outside environment, endotherms have a higher metabolic rate than ectotherms. Thus, endotherms have higher energy requirements to feed their higher metabolic rate. This has implications in terms of the ecology and evolution of these species. Given that endotherms maintain a constant body temperature, they can remain active over a wide range of different environments, from the Arctic to hot deserts. However, they need to eat frequently. In contrast, ectotherms are more limited in the habitats in which they can live, but they have much lower energy requirements. As a result, ectotherms can often go for

long periods without eating. Some snakes, for example, only eat once a month.

Energy requirements also vary with body size. When researchers have measured the metabolic rate of different species, they discovered that larger species have a higher metabolic rate than smaller species, as you can see in **FIGURE 52.2a**. This makes sense in that an elephant requires more energy each day than a mouse, so the elephant needs to eat a lot more food every day to provide this energy. This also means that a given area of land can support a much larger population of mice than elephants. Finally, this means if more

food becomes available in the environment, the populations of elephants and mice can both increase.

FIGURE 52.2 Metabolic rates of mammals and body size

We can measure metabolic rate by measuring the amount of oxygen gas consumed by different animals when at rest. (a) Larger mammals have a higher metabolic rate than smaller mammals. (b) When we examine metabolic rate on a per-kilogram basis, we see that larger mammals have a lower metabolic rate per kilogram of body mass. Larger mammals have a small surface area relative to their volume, so they experience less heat loss to the

environment. As a result, large mammals need to generate less heat to maintain their body temperature.

Data from Brody, S. 1945. *Bioenergetics and Growth.* New York: Reinhold Publishing Corporation.

Another way of looking at metabolic rates among mammals of different sizes is to examine the relationship on a per kilogram basis, as shown in Figure 52.2b. In this case, we see that the largest mammals have the lowest metabolic rate on a per-kilogram basis. As you will recall from Unit 2, as an organism increases in size, its volume increases rapidly while its surface area increases slowly. As a

result, larger bodies have a smaller surface area relative to their volume than smaller bodies, so they lose heat to the environment more slowly and therefore they need less energy on a per kilogram basis. Thus, while larger animals require more total food, they require less food per kilogram of mass.

Energy Availability and Reproductive Strategies

Energy availability also determines the reproductive strategies of organisms. We can see examples of this by looking at the seasonal nature of reproduction. For example, in

North America, many species of plants flower in the spring when rising temperatures warm the air and soil, and more hours of sunlight are available so that the plants can generate sugars through photosynthesis. Other species of plants have evolved to initially put all their energy into their growth throughout the spring and summer and then flower in the fall, once they have accumulated sufficient energy reserves for making flowers and fruits.

Some plants take even longer to reproduce. For example, the common mullein (*Verbascum thapsus*) lives in open fields and requires 2 years to

gain enough energy to flower. In the first year, it only grows into a short plant with many large leaves, which is illustrated in **FIGURE 52.3a**. As the plant photosynthesizes during its first year, it stores much of its energy in its root. In the second year, the mullein continues to photosynthesize and then uses its large amount of stored energy from 2 years of photosynthesis to grow a tall flowering stem that is more than 1 m high, which you can see in Figure 52.3b.

FIGURE 52.3 Timing reproduction to available energy

The common mullein grows in fields around the world, and it requires 2 years to flower. (a) In the first year, the mullein

is a short plant that photosynthesizes and stores much of its surplus energy in its roots. (b) In the second year, the mullein grows much taller and uses the energy it has gained over 2 years to produce a flower stalk that is more than 1 m tall.

Large plants such as trees typically require many years of growth before they have accumulated enough energy to start reproducing. This also allows the trees to put their energy into growing taller to rise above the height of many other competing plants before allocating any energy to making flowers and seeds. Thus, different species of plants have evolved different strategies to gain

evolutionary fitness.

Animals also time their reproduction to energy availability. For instance, large mammals breed in the fall so that their offspring are born in the spring, when food is very abundant. This means that the offspring have plenty of food to begin their life, but it also means that the offspring have the entire summer to grow and store fat before the onset of winter, when food is much less abundant. During the winter, they must either live off their fat reserves and the scarce food that they can find or have the energy to migrate to warmer climates, such as geese, which fly south every fall and then fly back north in the spring. As

you can see, the different ecological strategies of how organisms live their lives is strongly affected by energy availability and energy use.

✓ Concept Check

1. **Describe** the difference between endotherms and ectotherms.

2. **Describe** three ways that terrestrial ectotherms can adjust their behavior to thermoregulate.

3. **Describe** the relationship between animal size and their per-kg metabolic rate.

52.2 Energy is captured and

moved through ecosystems

All organisms need energy to survive, grow, and reproduce. Some obtain energy from the sun and from inorganic molecules, while others obtain energy from consuming other organisms. In this section, we will examine how energy is captured and how it is moved through different species that live in an ecosystem.

Energy Capture

There are multiple ways that organisms have evolved to capture the energy that they need. In Unit 3, we discussed how some organisms use photosynthesis to capture solar energy and convert carbon dioxide

and water into sugars. An alternative strategy, especially in places that have no sunlight available, is to obtain energy from chemical compounds to build sugars, which we call **chemosynthesis**. For example, at the bottom of the deep ocean there are thermal vents that continuously release hydrogen sulfide gas (H2SH_2S). At these depths, there is no sunlight, so specialized bacteria have evolved to use the energy in the chemical bonds of the hydrogen sulfide to power the conversion of carbon dioxide and water into sugars, as shown in **FIGURE 52.4**. We can see an example of this in the specialized species of bacteria that live in tube worms that live near sea vents.

Regardless of the process used to capture this energy, the energy stored in these sugars can be extracted through the process of cellular respiration, as we noted in Unit 3.

FIGURE 52.4 Chemosynthesis

In the deepest part of the ocean, vents on the ocean floor release hydrogen sulfide gas. Specialized bacteria have evolved to obtain the energy in hydrogen sulfide bonds to power the conversion of carbon dioxide and water into sugar. (a) Vents on the ocean floor releasing hydrogen sulfide gas. (b) Tube worms, which contain chemosynthetic bacteria, live near vents that release hydrogen sulfide gas.

Trophic levels and Food Chains

Ecologists categorize organisms according to how they obtain energy. Organisms that obtain energy by photosynthesis or chemosynthesis are known as **autotrophs**, or producers. Autotrophs include plants and algae. Organisms that obtain energy by eating other organisms are called **heterotrophs**, or consumers. Heterotrophs acquire energy from consuming the organic compounds that are synthesized by other organisms. They do this through the process of catabolism in which they obtain energy by breaking down the carbohydrates, lipids, and proteins of

other organisms. Heterotrophs are further categorized depending on which types of organisms they consume. Primary consumers are herbivores that eat the plants or algae, such as zebras that eat grasses on the plains of Africa. Secondary consumers are carnivores that eat primary consumers, such as the lions that eat the zebras. Tertiary consumers are carnivores that eat secondary consumers, such as bald eagles that eat fish, which eat tiny herbivores.

Autotrophs and heterotrophs can be organized into successive levels, which we call **trophic levels.** Based on these trophic levels, we can draw

food chains that depict the direction of energy and matter flow between trophic levels. You can see an example of trophic levels and food chains in **FIGURE 52.5**, which begins with primary producers at the base and is followed by primary, secondary, and tertiary consumers. Given that larger rectangles in the pyramid indicate a greater amount of biomass, we can see that most of the biomass resides in the producers with less biomass in each higher level of the consumers. In some communities there are only three trophic levels. For example, in the African plains, lions eat gazelles and gazelles eat grasses, so we only have three trophic levels. In other communities, there

can be four trophic levels, such as the food chain in the figure in which grass is eaten by mice, which are eaten by snakes, which are eaten by hawks.

FIGURE 52.5 Trophic levels

Based on how organisms obtain their energy, we can order autotrophs and the various types of heterotrophs into successive levels that represent the flow of energy in an ecosystem into simplified food chains. Some food chains, such as those that include lions, zebras, and grasses, only have three trophic levels. Other food chains, such as a lake containing algae, zooplankton, fish, and bald eagles, can have four trophic levels.

Now that we understand that energy is transferred up through multiple trophic levels, we can ask how efficiently this energy moves from one trophic level to another. For example, of the 1000 kg of biomass present in the producers, what percentage is transferred to the primary consumers and secondary consumers? We can answer this question by examining the amount of biomass present in each trophic level. In this example, only 10% of the producer mass is transferred to the primary consumers. This low efficiency occurs because not all producers are consumable, such as plants with thorns which deter herbivores. Moreover, not all

consumed producers are fully digestible. In addition, the transformation of energy is never 100%, as noted in our discussion of the second law of thermodynamics (see Module 13).

In the same way, we see in our example that only 10% of the mass from the primary consumers is transferred to the secondary consumers. This happens because some primary consumers have evolved defenses against being consumed, those primary consumers that are consumed are not fully digestible, and a substantial portion of the energy consumed by secondary consumers is used for maintaining

their bodies and generating heat. The remaining energy can be used for growth and reproduction. Collectively, this means that of all the energy available in the producer level, only 1% makes it to the secondary consumer level. While a 10% ecological efficiency is a helpful rule of thumb, actual measurements of ecological efficiency generally range from 5% to 20%.

Based on our knowledge of ecological efficiency, we can also see that it places a limit on how many trophic levels can exist in a community. Having more energy available in the producer level and having higher ecological efficiencies would result in

more energy available in the secondary consumers, which would allow a larger population of secondary consumers. As the number of secondary consumers increases, it can become high enough to support a population of tertiary consumers. For example, imagine a field of plants that can support a population of 20 white-tailed deer. If we fertilize the field to grow more plants, the field will then also be able to feed more deer. With more deer present, there may now be enough deer to support a population of deer predators, such as wolves or mountain lions. In the same way, anything that reduces the abundance and growth of the producers will reduce the abundance of the higher

trophic levels and may cause a loss of the highest trophic level because there is not enough energy available at that level.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be familiar with trophic pyramids and be able to analyze the flow of energy through them.

Food Webs

While categorizing species into a small number of trophic levels helps us see the big picture of how energy flows, real communities generally have a large number of species and many of them do not fit neatly into

the four trophic categories shown in Figure 52.5. Instead, we commonly find that species cannot be lined up in a simple linear way. In addition, we can have species that are omnivores, which feed on both producers and other consumers. Finally, our trophic levels and simple food chains did not include those consumers of dead organic matter. These consumers include scavengers such as condors that eat dead animals, detritivores such as earthworms that break down dead organic and waste products into smaller particles, and decomposers such as fungi and bacteria that convert the dead organic matter into molecules and elements that can be recycled by the producers.

To represent a community of interacting species in a more realistic way, we use food webs, which are depictions of how energy and matter flow among a large number of species. The food web in **FIGURE 52.6** shows species interacting in adjacent aquatic and terrestrial habitats. Note that the arrows indicate the direction of energy movement. In this figure, you can see a large number of species interacting, with some species feeding on multiple trophic levels. You can also see scavengers, detritivores, and decomposers feeding on the waste products and dead organisms.

FIGURE 52.6 A simplified food web

In contrast to food chains, food webs show many more species interacting and the ways in which a given species might consume multiple trophic levels rather than only a single trophic level below, as depicted in food chains. Arrows indicate the direction of flowing energy and matter. A complete food web would show many more species and many more arrows depicting the flow of energy and matter.

✓ Concept Check

4. **Identify** four trophic levels.

5. **Describe** the difference between a food chain and a food web.

6. **Identify** why the amount of energy

in successive trophic levels declines.

Morris, et al, *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

52.3 Matter cycles in ecosystems

Most of the energy that moves through communities and ecosystems originates from the sun and is captured through photosynthesis, although a small fraction originates from chemosynthesis. As this energy moves through the food web, much of it is converted into heat and this heat is ultimately lost to space. Thus,

energy comes into an ecosystem, moves through the ecosystem, and eventually leaves the ecosystem.

In contrast, matter cycles within an ecosystem. This matter includes many important elements that cycle through the air, water, soils, and organisms, such as nitrogen, phosphorus, sulfur, and carbon. Given that these elements move around in a cycle, we can think about pools and processes. The pools are places in which an element resides whereas the processes are the ways in which an element moves from one pool to another. For example, we can find a substantial amount of nitrogen in plants that die each fall, so the

plants represent a pool of nitrogen. The nitrogen can then be released to the soil through plant decomposition, which represents a process. A prime example of element cycling can be found by tracking the movement of carbon and seeing how human activities are having major impacts on both carbon pools and processes.

The Carbon Cycle

As you may recall from previous modules, carbon is an incredibly important element that is found in a wide variety of molecules on Earth including the molecules that comprise cell membranes, proteins, sugars, and the ATP molecule used as

an accessible source of cellular energy. In fact, carbon makes up about 20% of an organism's dry mass, which is the mass of the organism's body after removing the water. In the carbon cycle, illustrated in **FIGURE 52.7**, we see that carbon moves between pools in the air, water, and land using several processes.

FIGURE 52.7 The carbon cycle

There are seven important processes that move carbon among the many pools where it resides. Photosynthesis by plants and algae takes up $CO2$ CO_2 while cellular respiration and decomposition cause the release of $CO2$ CO_2. Exchange of $CO2$ CO_2 between waterbodies and the air occurs at nearly

equal rates. Some CO_2 that is dissolved in the ocean combines with calcium to form $CaCO_3$, which precipitates out into an ocean sediment. Some organic matter that is not fully decomposed can become buried and get converted into fossil fuels. Humans have used extraction to move these fossil fuels to Earth's surface and then have used combustion to power homes, businesses, and automobiles.

The two most familiar processes in the carbon cycle are photosynthesis and cellular respiration, which we discussed in Unit 3. Organisms that photosynthesize take CO_2 out of the air and water and convert it into

sugars that can subsequently provide the energy for growth and reproduction. This carbon can be moved through the food web to the consumers, scavengers, detritivores, and decomposers. At the same time, all species carry out cellular respiration, which converts organic molecules such as sugars back into CO2CO_2. In addition, decomposers break down dead organisms to obtain energy and release CO2CO_2 into the air and water.

Carbon also moves between pools using the processes of exchange, sedimentation, and burial. Exchange is the process of CO2CO_2 moving between bodies of water and the

atmosphere; the amount leaving the ocean is approximately equal to the amount that enters the ocean. Sedimentation occurs when dissolved CO2CO_2 in the water combines with calcium ions to form calcium carbonate (CaCO3$CaCO_3$). Calcium carbonate is not very soluble in water, so the compound precipitates out of solution, landing on the ocean bottom. Over time, this calcium carbonate accumulates into large layers that are known as limestone or dolomite. Over millions of years, this process has produced a massive pool of carbon as ocean sediments. In some cases, dead organic matter is not completely decomposed in elements before the

organic matter gets buried. In this case, the organic matter can become fossilized and a portion of it can be transformed into fossil fuels. The rate of carbon removal from oceans by burial is offset by approximately the same amount of carbon that is released by the weathering of limestone rocks and by volcanic eruptions.

The final two processes in the carbon cycle are extraction and combustion. Extraction is the removal of buried carbon, including coal, oil, and natural gas. Extraction by itself does not convert carbon into another form. It simply moves the buried fossil fuels from deep underground to the

surface where it can be used. The combustion of fossil fuels is the process that actually transforms the fossil fuels from fossilized carbon sources into CO2CO_2, much like the process of cellular respiration. Combustion also occurs with volcanoes and forest fires, both of which produce substantial amounts of CO2CO_2. "**Visual Synthesis 8.2: The Movement of Carbon Through Ecosystems**" provides an additional illustration of the terrestrial and marine carbon cycles.

Human Impacts on the Carbon Cycle

With our understanding of the carbon

cycle, we can now examine how human activities have disrupted the carbon cycle. As we have just seen, without human impacts, the amount of carbon moved among pools by one process is approximately offset by some other process. Human activities have altered that natural balance. For example, the large-scale combustion of fossil fuels by humans is a relatively recent activity, growing rapidly only during the past two centuries since the Industrial Revolution.

Today, humans contribute a large amount of CO2CO_2 into the atmosphere from burning fossil fuels to heat their houses and businesses,

power their cars, and provide the energy for industry and agriculture. In addition, logging large forests, often accompanied by burning the logged areas, has converted a large amount of carbon that was locked up in the bodies of the trees into CO2CO_2 that was sent into the atmosphere. We will have much more to say about the consequences of increasing CO2CO_2 in the atmosphere in Module 57.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be able to describe the impact humans have had on the carbon cycle and identify the ways humans have mobilized carbon pools and increased carbon dioxide in the

atmosphere.

✓ Concept Check

7. **Distinguish** between pools and processes in the cycling of carbon.

8. **Describe** how carbon combustion by human activities has altered the pools of carbon in the carbon cycle.

Module 52 Summary

REVISIT THE BIG

PREP FOR THE AP® EXAM

ENERGETICS: Consider the energy-capturing strategies of related organisms. Choose two related organisms and **describe** how their strategies for capturing energy from their environment reflect continuity through common ancestry.

LG 52.1 There are different strategies for acquiring and using energy.

- The process of an organism controlling its body temperature is known as thermoregulation. Page 736

- We can distinguish between organisms with body temperatures that are regulated internally, known as endotherms, and organisms with body temperatures that are regulated by external conditions, known as ectotherms. Page 737
- Most plants are ectotherms, although some have fascinating physiological adaptations to internally generate heat. Page 737
- Many species of ectothermic animals can adjust the temperature of their bodies by altering their behavior. Page 737
- A net gain in energy allows an individual to experience growth and reproduction, which can lead

to an increase in the size of a population. Page 738

- A net loss of energy results in lost growth, reproduction, and survival, which can lead to population declines. Page 738
- Endotherms have a higher metabolic rate than ectotherms, which means that endotherms have higher energy requirements to feed their higher metabolic rate. Page 738
- Larger species have a higher metabolic rate than smaller species, but larger species have a lower metabolic rate on a per-unit-mass basis than smaller ones. Page 739
- Energy availability also

determines the reproductive strategies of organisms, including the seasons for breeding. Page 739

LG 52.2 Energy is captured and moved through ecosystems.

- Ecologists categorize organisms according to how they obtain energy. Autotrophs, or producers, obtain energy by chemosynthesis or photosynthesis. Heterotrophs, or consumers, obtain energy by eating other organisms. Page 740
- We can arrange the different producers and consumers into successive levels, which we call trophic levels. Page 741
- Based on these trophic levels, we

can draw food chains that depict the direction of energy and matter flow between trophic levels. Page 741

- To represent a community of interacting species in a more realistic way, we use food webs, which are depictions of how energy and matter flow among a large number of species. Page 741
- A trophic pyramid depicts the amount of energy present in each trophic level. Page 741
- We can determine the percentage of available energy that makes its way from one trophic level to the next, which is called ecological efficiency. Page 742

LG 52.3 Matter cycles in ecosystems.

- Matter moves through communities and ecosystems in a cycle. Page 743
- Pools are places in which an element resides, whereas processes are the ways in which an element moves from one pool to another. Page 743
- The processes that move carbon in a cycle are photosynthesis, cellular respiration, exchange, sedimentation, burial, extraction, and combustion. Page 743
- Today, human activity releases a large amount of CO 2 CO_2 into the atmosphere, including burning fossil fuels for heat, to power cars, and to provide energy for industry and agriculture. Page 744

Review Questions

1. Which statement is false about endotherms and ectotherms?

    A. Ectotherms maintain a body temperature that matches their environment.
    B. Endotherms maintain a constant body temperature.
    C. Ectotherms can vary their

body temperature using thermoregulatory behaviors.

D. Endotherms require more energy than ectotherms.

2. Which statement is true about endotherms versus ectotherms?

A. Ectotherms need to consume more food than similar-sized endotherms.

B. Endotherms can occupy a wider range of habitats than ectotherms.

C. Large endotherms require less energy than small ectotherms.

D. Endotherms can go for long periods of time without eating.

3. What is the relationship between

mammal size and metabolic rate?

A. Larger mammals have a lower metabolic rate than smaller mammals.
B. Smaller mammals have a higher metabolic rate than larger mammals.
C. Larger mammals have a lower per-kg metabolic rate than smaller mammals.
D. Smaller mammals have a lower per-kg metabolic rate than larger mammals.

4. Which statement is true about how energy availability affects reproductive strategies of organisms?

A. Animals can reproduce at any

time of the year.

B. Larger plants such as trees commonly reproduce in their first year of life.

C. Plant reproduction is not affected by energy availability.

D. Animals reproduce when abundant food is available.

5. Which statement is false about the carbon cycle?

A. Human combustion of fossil fuels has had no effect on the carbon cycle.

B. Sedimentation brings carbon to the bottom of the ocean.

C. Photosynthesis and respiration are approximately equal in their movement of carbon.

D. Exchange is the movement of carbon between the water and the air.

Module 52 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

1. Carbon is a key element necessary for life. If all decomposers were eliminated from the Earth, which situation would be likely to happen?

A. Life would be unaffected as there are many other processes in the carbon cycle that would compensate for the lack of decomposers.
B. Life would eventually stop because all Earth's carbon would be trapped in dead materials.
C. Life would slow down but continue as the function of the decomposers would be taken over by the respiring organisms.
D. Life would continue unaffected as the rest of the carbon cycle would increase its rate.

Questions 2 and 3 refer to the following information.

The body temperature data in the table were collected from two different species in the same habitat over the course of the same 15 hours of the same day. Numbers in parentheses are ±2 standard errors of the mean.

Time of day	Outside temperature (°C)	Body temperature species 1 (°C)	Body temperature species 2 (°C)
6 a.m.	41 (±1)	23 (±2)	
9 a.m.	42 (±2)	28 (±3)	
12 p.m.	41 (±1)	32 (±4)	
3 p.m.	41 (±1)	33 (±3)	
6 p.m.	40 (±2)	29 (±2)	
9 p.m.	41 (±1)	26 (±2)	

1. Determine the average body temperature of species 1 over the course of this experiment.

A. 25°C
B. 24°C
C. 26°C
D. 28°C

2. Which conclusion is supported by the data in the table?

A. Species 1 regulates its body temperature.
B. Species 2 regulates its body temperature.
C. Species 1 had its lowest body temperature at the coldest time of the day.
D. Species 2 had its highest body temperature at the coldest time of the day.

Questions 4 and 5 refer to the

following information.

Blue jays are a species of bird that lives the eastern and central United States. Students in an AP® Biology class observed a population of blue jays near their school eating acorns, berries, and seeds.

1. Ecologists often follow the movement of energy from one trophic level to another. If we consider the energy of the acorns, berries, and seeds to be 100%, what portion of that energy would be expected to be in the biomass of the blue jays that consume these food sources?

   A. 100%

B. 50%

C. 10%

D. 1%

2. The students observe that hawks prey upon the blue jays living near their school. What portion of the energy of the acorns, berries, and seeds would be expected to be in the biomass of the hawks that consume the blue jays?

A. 100%

B. 50%

C. 10%

D. 1%

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Researchers studying a grassland habitat observe interactions among four animal species: hawk, fox, mouse, and grasshopper. They record their observations of the interactions in the following food web.

a. In the habitat being studied, the total mass of the grass is 8000 kg. **Calculate** the total mass of the hawk population in the habitat.
b. At some point during the

observation period, an herbicide is sprayed on the grass. The herbicide kills 85% of the grass and prevents the surviving grass from growing and producing seeds. **Predict** what will happen to the hawk populations in the terrestrial habitat. **Justify** your prediction.

c. Shortly after the herbicide kills 85% of the native grass, a quick-growing, herbicide-tolerant grass species is planted in this ecosystem. **Predict** what effect this grass species will have on the ecosystem and **justify** your answer.

VISUAL SYNTHESIS 8.1 HOMEOSTASIS AND THERMOREGULATION

Endotherms, such as the rock squirrel, use a variety of physiological and behavioral adjustments to maintain a stable body temperature as they experience cold nights, cool days, and hot days. In ectotherms, such as the zebra-tailed lizard, body temperature is much more variable and is determined by the air temperature of the environment as well as behavioral and physiological changes to maintain a

small range of temperatures.

Terrestrial carbon cycle
In terrestrial ecosystems, carbon enters food webs through photosynthesis and is transferred through food webs to consumers. Decomposers complete the return of carbon to the atmosphere or CO_2.
CO_2

LEARNING GOALS

- **LG 53.1 Populations have particular characteristics.**
- **LG 53.2 Population growth is determined by births and deaths.**
- **LG 53.3 Species have evolved adaptations that are related to population growth.**

In the field of ecology, one of the most interesting observations is that species vary a great deal in how much

their population size fluctuates over time. We see that the population size of some species such as deer, antelope, and other large mammals grows slowly and once it reaches a certain level it remains fairly stable over time. In contrast, the population size of many smaller species of mammals, insects, and amphibians grows rapidly and experiences high rates of death early in life, and therefore exhibits large fluctuations over time. Understanding the factors that drive these changes in population size is the science of population ecology. Population ecology provides us with insights into the factors that promote population growth as well as factors that limit population growth.

These factors are relevant to all organisms including humans. In this module, we will explore several characteristics of populations that can affect population growth. We will then examine a mathematical model of population growth, which allows us to predict the future growth of populations. With this understanding, we will examine some adaptations of species that are related to how their populations grow.

53.1 Populations have particular characteristics

In our introduction to ecology in Module 51, we defined a population as all individuals of a species living within a given area. The area may be very large, such as the number of

deer on an entire continent, or it may be delineated to be much smaller, such as the number of mountain lions in Montana or the number of frogs in a pond. In this section, we will examine several characteristics of populations that affect the size and growth rate of populations.

Population Size and Density

Population size is the number of individuals in a given area. For example, we could count the number of barn owls in your town or the number of dandelions in your yard. When a population size is very large or the area is expansive, it can be

difficult or impossible to determine the population size for a species. In such cases, ecologists have devised ways of estimating population size. This is discussed in "Practicing Science 53.1: How many butterflies are in a given population?" As shown in **FIGURE 53.1**, one of the techniques scientists use to estimate the size of a population is called mark-and-recapture.

FIGURE 53.1 Mark-and-recapture

Biologists can estimate population sizes by collecting a sample of a populations, marking the collected individuals, and then releasing them back into the larger population. In this example, a sample of monarch butterflies in Florida was

collected and each was given a unique mark on the wing. A second collection of the population made a few days later, which included both marked and unmarked individuals, help biologists estimate the size of the entire population.

Practicing Science 53.1

How many butterflies are in a given population?

PREP FOR THE AP® EXAM

Background Biologists estimate population sizes of many animals using a technique known as mark-and-recapture, which involves capturing and marking a sample of individuals,

releasing them back into the wild, and then capturing another sample of individuals a few days later. This technique was used to estimate the population size of monarch butterflies (*Danaus plexippus*) in Florida.

Method Biologists captured the butterflies in a field, marked the butterflies with an identification sticker on the wing, and then released them. The number of marked butterflies was recorded. The next day, a second sample of monarch butterflies was captured, and the number of marked and unmarked butterflies was recorded. The marked butterflies that were captured again on the second day are called recaptures.

Using this technique, researchers

estimated the butterfly population size (*N*) in several steps. First, they determined the total number of marked butterflies and unmarked butterflies caught on the second day (*C*). They divided *C* by the number of recaptures (*R*). Finally, they multiplied $\frac{C}{R}$ by the number of butterflies marked on the first day (*M*), as follows:

$$N = \left(\frac{C}{R}\right) \times M$$

ResultsLet's say that 100 butterflies are captured, marked, and released on the first day. On the second day, 120 butterflies are captured, 30 of which are recaptures that have marks. The rest are unmarked. Using the above equation:

$$N = \left(\frac{120}{30}\right) \times 100 = 4$$

$$N = \left(\frac{C}{R}\right) \times M$$
$$N = \left(\frac{120}{30}\right) \times 100$$
$$N = (4) \times 100$$
$$N = 400$$

We conclude that the population size is 400 butterflies. As you can see, in our second sample of 100 butterflies, 25% were marked. Since we originally marked 100 butterflies, the entire population must be four times greater than the number of marked butterflies.

Related Methods This mark-and-recapture technique is extremely useful in estimating population sizes of organisms ranging from polar bears to possums. Many animals have distinctive color markings, such as the blotches on humpback whale tailfins and skin-

spotting patterns on frogs; these animals can be recorded without having to be marked. This technique assumes that the population size is approximately the same on the second day as it was on the first day. Biologists also assume that the captured and released animals mix with others in the population and do not intentionally avoid recapture on the second day.

Knight, A., L. P. Brower, and E. H. Williams. 1999. “Spring Remigration of the Monarch Butterfly *Danaus plexippus* (Lepidoptera: Nymphalidae) in North-Central Florida: Estimating Population Parameters Using Mark–Recapture.” *Biological Journal of the Linnean Society* 68:531–556.

AP® PRACTICE QUESTION

Some high school students read that

planting milkweed on the fields behind their school would increase the size of the monarch butterfly population because monarchs lay their eggs on the plant and the caterpillars feed on the leaves. The local middle school, about 5 miles away, has a field of about the same size, but without any additional milkweeds being planted. Design an experiment, using the mark-and-recapture method described, to determine if planting 100 milkweed plants affects the number of monarch visits to the field over the period of 1 year.

a. In your experimental design, **identify** the following:

    1. The question being investigated
    2. The hypothesis

3. The experimental group
4. The control group
5. The independent variable
6. The dependent variable

b. **Describe** how you could utilize standard error of the mean to help you analyze the data.

Population density is the number of individuals in a given area divided by the size of the area. By calculating density, we can determine whether a population is densely crowded or relatively scarce compared to other populations. For example, the density of coyotes in some regions of Texas is 12 individuals per square kilometer, while in other regions it is 1 individual per square kilometer. Knowing a population's density can

be useful if we wish to know whether a species has enough food in an area or if it will outstrip its food supply. It can also be useful when state fish and wildlife agencies are setting annual limits on how many birds and mammals can be harvested in different regions of a state by hunters and how many fish can be harvested from different lakes and streams by anglers.

Population Range and Distribution

The geographic range of a population is the area over which a population is spread. The geographic range is determined by where there are

favorable conditions for a species to live and whether individuals can get there. For example, many species of birds and mammals living in South America may be able to also live in parts of Africa, but the Atlantic Ocean prevents them from dispersing to Africa, so their geographic range remains restricted to South America.

In some cases, new species are accidentally introduced to a continent where they have never lived before. It can be helpful to know what abiotic and biotic conditions the species requires so that we can estimate where the introduced species is likely to spread. For example, the European starling is a bird that was first

introduced to the United States in 1890 and 1891 at a location near New York City. The original released population was 160 birds, but in less than 100 years the population's geographic range included the entire 48 contiguous states, as illustrated in **FIGURE 53.2**, and it numbered more than 7 million starlings.

FIGURE 53.2 Geographic range

When the starling was introduced to the United States in 1890 and 1891, it began as a population of 160 birds near New York City. Over the subsequent decades, the population rapidly grew and expanded its geographic range, which is now all 48 contiguous states.

Data from Kessel, B. 1953. "Distribution and

Migration of the European Starling in North America." *Condor* 55: 49–67; U.S. Geological Survey. 2003. https://www.mbr-pwrc.usgs.gov/bbs/htm03/ra2003_red/ra04930.htm

Population distribution is a measure of how clumped individuals are within their geographic range. The distribution of individuals can be random, uniform, or clumped. In a random distribution, there is no pattern in where individuals are with respect to other individuals, such as the trees shown in **FIGURE 53.3a**. In contrast, a uniform distribution occurs when all individuals are evenly spaced apart from each other, such as

the nesting seabirds that evenly space out their nests shown in Figure 53.3b. A clumped distribution occurs when individuals aggregate together, often in response to clumped distributions of food or when there are benefits of social behavior. Examples include schools of fish, flocks of birds, and the clumped distributions of meerkats (*Suricata suricatta*) shown in Figure 53.3c.

FIGURE 53.3 Population distributions

Individuals in a population can be distributed in three different ways. (a) Many species, such as these trees in the northeastern United States, show a random distribution. (b) Species of seabirds, such as these Australian

gannets (*Morus serrator*), establish small territories, which results in each bird's nest being evenly spaced from other nests. (c) Some species, such as these meerkats, have clumped distributions, which can reflect clumped food sources or benefits of being social, including watching out for predators.

Population Sex Ratio and Age Structure

The population sex ratio is the ratio of males to females. In most species, this ratio is roughly 50:50, which means there is an equal number of males and females. In some species, such as fig wasps, this ratio can be 1

male for every 20 females. Uneven sex ratios can have a large impact on the number of offspring that can be produced by a population, which means that it can also affect how rapidly a population can grow.

The population age structure describes the number of individuals in different age categories. As we will see in the next section in which we discuss mathematical models of population growth, we commonly assume that all individuals are capable of breeding. In real populations, however, there are young individuals that have not yet achieved sexual maturity; middle-aged individuals that are in their

breeding prime; and old individuals that are too old to breed, or breed less. As you might imagine, the number of individuals in these different age categories can have a large effect on the number of offspring produced by a population each year.

✓ Concept Check

1. **Describe** how age structure can affect population growth.

2. **Identify** the number of squirrels in a population if an initial sample of 20 squirrels is marked and released, and the next day another 20 squirrels are captured and half of them are marked.

3. **Describe** the difference between the geographic range and distribution of a population.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

53.2 Population growth is determined by births and deaths

Changes in population size have a wide range of implications. In

humans, for example, we often want to predict future population sizes to determine whether the world can continue producing enough food for a growing population. Similarly, ecologists often want to understand the increases and decreases in plant and animal populations to help protect them from going extinct. In this section, we will examine how ecologists have created mathematical models of population growth.

Birth and Death Rates

At the most fundamental level, the growth or decline of a population is determined by the number of births

versus the number of deaths. If births exceed deaths, the population will increase. If deaths exceed births, the population will decrease. The movements of individuals into a population—immigration—and out of a population—emigration—can also be important factors in population change, as summarized in **FIGURE 53.4**.

FIGURE 53.4 Changes in population size

A population can increase as a result of births and immigration of individuals into the populations. It can decrease as a result of deaths and emigration of individuals out of the population.

To understand population growth, scientists use a mathematical model. To keep things simple, we will assume that we do not have individuals immigrating into the population or emigrating out of the population. We begin by defining the population size as *N*. We can then define the change in population size per unit time as d N d t $\frac{dN}{dt}$, where *dN* indicates a change in population size and *dt* indicates a change in time.

Thus, d N d t $\frac{dN}{dt}$ indicates the rate of change in population size over time. To determine the rate of change in population size, we can identify population sizes at different points in time. For example, if we define N 0 N_0 as the population size at time 0

and N 1 N_1 as the population size at time 1, the following equation shows how a population changes in size from time 0 to time 1:

d N d t = N 1 − N 0

$$\frac{dN}{dt} = N_1 - N_0$$

When we measure births and deaths over a particular time, such as births and deaths per day, we are measuring birth and death rates. Given that the change in population size is fundamentally the result of birth rate (*B*) and death rate (*D*), we can rewrite the above equation as:

d N d t = B − D $\frac{dN}{dt} = B - D$

where:

d t = change in time B = birth rate D = dea

$dt =$ change in time

$B =$ birth rate

$D =$ death rate

$N =$ population size

For example, imagine that we wanted to know the change in population size from one year to the next. If the birth rate that year is 20 individuals per year and the death rate is 10 individuals per year, then the change in population size in that year is:

d N d t = 20 − 10 d N d t = 10 individua

$$\frac{dN}{dt} = 20 - 10$$

$$\frac{dN}{dt} = 10 \text{ individuals per year}$$

AP® EXAM TIP

PREP FOR THE AP® EXAM

Make sure you are familiar with the equation $dN/dt = B - D$ and know how to use it.

Per Capita Growth Rate

It can be difficult to determine whether an increase in population size is substantial or trivial unless we know the size of the initial population. If the population starts with 10 individuals and it grows by 10 individuals in a year, then the population has increased by 100%

and is therefore growing rapidly. However, if the population starts with 1000 individuals and it grows by 10 individuals in a year, then the population has only increased by 1%. To give us a sense of how much a population is growing, we therefore need to assess the growth of the population relative to the initial size of the population. We can do this by calculating the **per capita growth rate (*r*)**, which is the rate of population change divided by the size of the population:

$$r = \frac{dN}{dt} \div N$$

r = d N d t ÷ N

The per capita growth rate allows us to assess how rapidly a population is

expected to increase or decrease. When *r* is positive, the population will increase; when it is large in magnitude, the population will increase quite rapidly. For instance, in our earlier example, we had a population with d N d t = 10 $\frac{dN}{dt} = 10$ and a population size of 10. In this case:

r = d N d t ÷ N r = 10 ÷ 10 r = 1

$$r = \frac{dN}{dt} \div N$$
$$r = 10 \div 10$$
$$r = 1$$

However, if d N d t = 10 $\frac{dN}{dt} = 10$ and the population size is 1000, then *r* has a much smaller positive value:

r = d N d t ÷ N r = 10 ÷ 1000 r = 0.01

$$r = \frac{dN}{dt} \div N$$

$$r = 10 \div 1000$$

$$r = 0.01$$

In contrast to these examples, *r* can also be a negative value. When *r* is negative, the population will decrease because the birth rate is exceeded by the death rate. Finally, when *r* = 0, the population is stable because the birth rate exactly offsets the death rate. In this case, the population does not change in size over time.

"Analyzing Statistics and Data: Population Growth" reviews the use of the population growth equation and the per capita growth rate and provides a practice problem for you

to try.

ANALYZING STATISTICS AND DATA

Population Growth

PREP FOR THE AP® EXAM

The growth of a population can be challenging to track due to a number of natural processes that happen in an environment, such as immigration, emigration, and limited amounts of food. The population growth model exists to simplify the conditions under which scientists try to predict growth from one time point to another by assuming that there is no immigration or emigration and that food is never limiting.

The most important factor in determining population growth is the number of births and deaths occurring in that population. When births outnumber deaths, the population increases in size; when deaths outnumber births, the population decreases in size. If births equal deaths, then the population size does not change. As we have already seen, the basic population growth formula is $\frac{dN}{dt} = B - D$.

The per capita growth rate (*r*) formula is also useful to know in the context of population growth. It tells us how quickly a population is increasing or decreasing.

$$r = dN/dt \div N \text{ or } r = B - D/N$$

$$r = \frac{dN}{dt} \div N \quad \text{or} \quad r = \frac{B - D}{N}$$

PRACTICE THE SKILL

A group of scientists is closely monitoring an endangered hawk population. Over the course of 1 year, the team has noted that in the population of 150 adult individuals, 120 eggs hatched, 98 of those offspring did not survive, and 13 adult hawks died. Calculate the change in population size over this year and the per capita growth rate.

The question has provided us with the birth and death rates to use in the population growth formula. The birth rate is 120 individuals per year and the death rate is $98 + 13 = 111$ $98 + 13 = 111$ individuals per year. We can plug these numbers into the growth

formula to find the change in population size over this 1-year period:

$$\mathrm{d\,N\,d\,t = B - D\,d\,N\,d\,t = 120 - 111\,d\,N\,d}$$

$$\frac{dN}{dt} = B - D$$

$$\frac{dN}{dt} = 120 - 111$$

$$\frac{dN}{dt} = 9$$

The hawk population grew by 9 individuals that year.

To answer the second part of the question, we can use the per capita growth formula. We know the population size and have just solved for population change, so these two numbers can be entered into the equation:

$$\mathrm{r = d\,N\,d\,t \div N\,r = 9 \div 150\,r = 0.06}$$

$$r = \frac{dN}{dt} \div N$$
$$r = 9 \div 150$$
$$r = 0.06$$

Because *r* is positive, the birth rate of the hawk population exceeds the death rate and the population increased by 6%. In this case, *r* is relatively small in magnitude, meaning that the hawk population is increasing by only a few individuals per year. If *r* had been negative, the opposite would have been true. The death rate would exceed the birth rate and the population would be decreasing at a rapid rate.

Your Turn

The graph below depicts the population size of Japan from 1900 to 2005. Calculate the approximate population growth rate for the years 1920, 1960,

2000, and 2005. Describe what has happened to the population growth of Japan throughout this century.

Data from https://theatlas.com/charts/B10_pHGg7

The Exponential Growth Model

Now that we understand how birth rates and death rates affect the growth of a population, we can examine a population growth model that predicts population growth into the future. Ecologists have made many different variations of population models, but we will begin with a model that makes a number of

assumptions to simplify the model so we can see some important relationships. For this model, we will assume that the population experiences no immigration or emigration. We will also assume that births and deaths occur continuously throughout the year, such as we see in humans and bacteria. However, many plants and animals have distinct breeding seasons, and we could alter our model to accommodate this reality. Finally, while populations in nature commonly have constraints on their growth, such as a limited amount of food or a limited number of nesting sites, in this first model we are going to assume that the population has no constraints on its

growth. Under these assumptions, a population initially grows slowly but as the population increases it begins to experience very rapid growth because at each time step there are more and more individuals that can reproduce, as shown in **FIGURE 53.5**. As you can see in this figure, the increasing growth rate produces a J-shaped curve. While an assumption of growth without any constraints is not realistic, it allows us to begin with a simple model that we will later build on to include constraints on growth.

FIGURE 53.5 Exponential growth model

In the exponential growth model, the

population increases in size exponentially over time since at each time step there are more individuals that can reproduce.

This J-shaped population growth curve is produced by a mathematical model based on population size and population growth rate. Note that earlier we used *r* to indicate per capita growth rate, but here we use r max $r_{\max}$ to indicate the **maximum per capita growth rate** of a population, which is the growth rate when the population is living without any constraints. Under this assumption, the population grows rapidly over time and we call it the

exponential growth model:

$$\frac{dN}{dt} = r_{\max} N$$

d N d t = r max N

where:

d N d t = change in population size per unit

$\frac{dN}{dt}$ = change in population size per unit time

$r_{\max}$ = maximum per capita growth rate of the population

N = population size

In this model, we can predict the change in population size per unit time based on the current population size and the maximum per capita growth rate. Because we assume no constraints on growth, the population will grow faster whenever it has an increase in the maximum per capita growth rate (r max $r_{\max}$) or a larger

number of individuals that are reproducing (N).

Based on this equation, we can calculate the rate of population increase at any given population size. For example, if r max = 0.4 $r_{\max} = 0.4$ and N = 10 $N = 10$, then:

d N d t = r m a x N d N d t = 0.4 × 10 d N

$$\frac{dN}{dt} = r_{max} N$$

$$\frac{dN}{dt} = 0.4 \times 10$$

$$\frac{dN}{dt} = 4$$

This means that when the population has 10 individuals, we will add 4 more individuals during the next time step. If the population is much larger, such

as 80 individuals, the rate of population increase will be eight times larger, adding 32 individuals, which causes the J-shaped curve to rise much more quickly.

$$dNdt = rmaxNdNdt = 0.4 \times 80dN$$

$$\frac{dN}{dt} = r_{max}N$$

$$\frac{dN}{dt} = 0.4 \times 80$$

$$\frac{dN}{dt} = 32$$

Despite its many simplifying assumptions, the exponential growth model is an excellent starting point for understanding how populations grow over time. There are real populations in nature that exhibit exponential growth, at least when

they begin at low population sizes. However, as we noted earlier, no population can experience indefinite growth, because the growing populations become constrained by a limited food supply or some other constraint. In the next module, we will examine limits on population growth and how we modify our models to include such limits.

"Analyzing Statistics and Data: Exponential Growth" provides a review of the exponential growth model and a problem for you to try.

ANALYZING STATISTICS AND DATA

Exponential Growth

PREP FOR THE AP® EXAM

The exponential growth model is commonly used by scientists to predict the future growth or decline of a population. Exponential growth is represented by a J-shaped curve. Growth begins slowly, but as more and more individuals reach reproductive maturity, the population will rapidly increase. This curve is shown by the graph in Figure 53.5. As we have seen, the formula for exponential population growth is $\mathrm{d\ N\ d\ t\ =\ r\ max\ N}$

$$\frac{dN}{dt} = r_{\max} N.$$

The exponential growth model assumes that there are no constraints acting on the population, such as limited food or space, so the population is free to experience unlimited and rapid growth.

The model also assumes that the population experiences no emigration or immigration, and that births and deaths occur throughout the year.

The maximum per capita growth rate (r_{max}) is equal to $\frac{B - D}{N}$. Remember that *B* is the birth rate, *D* is the death rate, and *N* is the population size. While *r* may change depending on the variation in the birth rate or the death rate, r_{max} is constant even if the population size becomes very large because the population is not limited by resources.

PRACTICE THE SKILL

A group of scientists is investigating what would happen to a population of rabbits if it experienced exponential growth with different maximum per

capita growth rates over 6 months. The initial population of rabbits consisted of only 2 individuals.

Using the exponential growth rate formula, fill in the missing data in the two tables below, one where $r\ max = 0.5$ $r_{max} = 0.5$ and one where $r\ max = 1.5$ $r_{max} = 1.5$. Graph each set of data and describe how different $r\ max$ r_{max} values affect the population.

$r\ max = 0.5$ $r_{max} = 0.5$	
Month	**Population size**
1	2
2	3
3	5
4	7
5	
6	

$r\ max = 1.5$ $r_{max} = 1.5$	

Month	Population size
1	2
2	
3	12
4	
5	75
6	187

To use the exponential growth equation, we must have two of three variables. The question provides the number of rabbits in the population, *N,* and the r max $r_{\max}$ values. We can enter each of these into the growth equation to solve for the increase in population size and then fill in the tables.

To find the size of the population at 5 months, we must first find the exponential growth rate at 4 months:

$$\mathrm{r\ m\ a\ x}\ 0.5\ :\mathrm{d\ N\ d\ t} = \mathrm{r\ max\ N\ d\ N\ d\ t} = 0.$$

$$r_{max} 0.5 : \frac{dN}{dt} = r_{\max} N$$

$$\frac{dN}{dt} = 0.5 \times 7$$

$$\frac{dN}{dt} = 3.5$$

The exponential growth rate when there are 7 rabbits in the population and r max $r_{\max}$ is 0.5 equals 3.5. This means that 3.5 rabbits, which we will round down to 3 rabbits, will be added to the population in the next time step of 1 month.

$$\text{Population at 5 months} = \text{population at 4 mon}$$

Population at 5 months = population at 4 months + 3 rabbits

$$\text{Population at 5 months} = 7 + 3 = 10 \text{ rabbits}$$

Population at 5 months = 7 + 3 = 10 rabbits

Now that we know there are 10 rabbits after 5 months, we can use this number to solve for the exponential growth rate

at 5 months:

$$\mathrm{r\ m\ a\ x\ 0.5\ :\ d\ N\ d\ t\ =\ r\ max\ N\ d\ N\ d\ t\ =\ 0.}$$

$$r_{max} 0.5 : \frac{dN}{dt} = r_{\max} N$$

$$\frac{dN}{dt} = 0.5 \times 10$$

$$\frac{dN}{dt} = 5$$

The exponential growth rate when there are 10 rabbits in the population and $\mathrm{r\ max}$ $r_{\max}$ is 0.5 equals 5. This means that 5 rabbits will be added to the population in the next time step of 1 month.

$$\text{Population at 6 months} = \text{population at 5 mon}$$

Population at 6 months = population at 5 months + 5 rabbits

$$\text{Population at 6 months} = 10 + 5 = 15 \text{ rabbit}$$

Population at 6 months = 10 + 5 = 15 rabbits

Now we can move on to completing the

table for r max = 1.5 $r_{\max} = 1.5$. Again, to find the size of the population at 2 months, we must first find the exponential growth rate at 1 month:

r m a x 1.5 : d N d t = r max N d N d t = 1

$$r_{max} 1.5 : \frac{dN}{dt} = r_{\max} N$$

$$\frac{dN}{dt} = 1.5 \times 2$$

$$\frac{dN}{dt} = 3$$

When the rabbit population has 2 individuals and a max per capita growth rate of 1.5, then the population will add 3 individuals at the next time step of 1 month.

Population at 2 months = population at 1 mon

Population at 2 months = population at 1 month + 3

Population at 2 months = 2 + 3 = 5 rabbits

Population at 2 months = 2 + 3 = 5 rabbits

For the last empty cell in the table, we will calculate the exponential growth rate at 3 months to find the population size at 4 months:

$$\mathrm{r\ m\ a\ x\ 1.5\quad :\ d\ N\ d\ t\ =\ r\ max\ N\ d\ N\ d\ t\ =\ 1}$$

$$r_{max} 1.5 : \frac{dN}{dt} = r_{\max} N$$

$$\frac{dN}{dt} = 1.5 \times 12$$

$$\frac{dN}{dt} = 18$$

When the rabbit population has 12 individuals and a max per capita growth rate of 1.5, the population will add 18 individuals at the next time step of 1 month.

$$\mathrm{Population\ at\ 4\ months\ =\ population\ at\ 3\ mon}$$

Population at 4 months = population at 3 months + 18

$$\mathrm{Population\ at\ 4\ months\ =\ 12\ +\ 18\ =\ 30\ rabbi}$$

Population at 4 months = 12 + 18 = 30 rabbits

We have completed the second table and can graph the data to show the exponential growth rate of each rabbit population.

The larger $\mathrm{r\ max}$ $r_{\max}$ value has drastically increased how quickly the rabbit population is growing. The number of individuals added to the population at each time step is much greater with an $\mathrm{r\ max}$ $r_{\max}$ value of 1.5 than with an $\mathrm{r\ max}$ $r_{\max}$ value of 0.5. A smaller $\mathrm{r\ max}$ $r_{\max}$ means a slower rate of growth, resulting in fewer individuals being added after each period of time passes. A larger $\mathrm{r\ max}$ $r_{\max}$ means a faster rate of growth, resulting in more individuals being added after each period of time passes, and a steeper

curve.

Your Turn

The protozoa *Paramecium caudatum* is known for being used in population growth studies. This species can exhibit exponential growth if laboratory conditions are favorable. *P. caudatum* has a max per capita growth rate of 0.94. Calculate the exponential growth rate of *P. caudatum* at *N* of 50; 2500; and 10,000. Describe the trend that you observe.

✓ Concept Check

4. **Describe** how birth rate and death rate determines population growth rate.

5. **Distinguish** the difference that a low versus high maximum per capita growth rate has on population

growth.

6. **Describe** why the exponential growth model produces a J-shaped curve of population growth.

53.3 Species have evolved adaptations that are related to population growth

As we have seen, different species have different population growth rates, which are the result of

evolution. Some species have evolved very high reproductive rates, which can be beneficial in species that face a risk of dying early in life. Other species have evolved relatively low reproductive rates, which reflects their low risk of dying early in life. In this section, we will examine how different species face different survival probabilities over time and how this has shaped the evolution of their maximum per capita growth rates (rmax$r_{\max}$).

Survivorship Curves

When we examine the probability of species surviving over their lifetime, they generally follow one of three

patterns, as shown in **FIGURE 53.6**. For a Type I survivorship curve, individuals experience high survival throughout most of their life and then their survival declines sharply later in life. Examples of Type I species include humans and other large mammals including deer, buffalo, and elephants. For a Type II survivorship curve, individuals experience steadily declining survival throughout their entire life. Species following this pattern include birds and small mammals such as squirrels. For a Type III survivorship curve, individuals experience a sharp drop in survival early in life and then a slower decline throughout the rest of their life, with few individuals

reaching adulthood. Examples of such species include mosquitoes, amphibians, and many small species of plants such as dandelions.

FIGURE 53.6 Survivorship curves

Species with Type I survivorship curves experience high survival throughout most of their life and then low survival late in life. Species with Type II survivorship experience steadily declining survival throughout their entire life. Species with Type III survivorship experience low survival early in life and then slower decline throughout the rest of their life.

K- and *r*-selected

Species

The evolved differences in survivorship over time among different species are associated with differences in evolved reproductive strategies, as shown in **FIGURE 53.7**. For example, the exponential model assumes no constraints on growth. However, most species experience a limit on how many individuals can be supported in a given area, which we define as the environment's **carrying capacity**, and denote as *K*. Over evolutionary time, some species have evolved to have relatively slow reproduction and remain near the environment's carrying capacity, so we refer to them as *K*-selected

species. These species—including chimps, elephants, horses, and humans—commonly exhibit a Type I survivorship curve.

FIGURE 53.7 Comparing *K*- versus *r*-selected species

(a) The chimpanzee takes about 10 years to achieve maturity and then has a single offspring every 3–6 years. (b) In contrast, frogs mature in 1–2 years and lay hundreds of eggs every spring.

Given that *K*-selected species are those with populations that tend to stay near the environment's carrying capacity, they generally have low maximum per capita growth rates. These low growth rates are often found in large mammals that take

many years to reach sexual maturity and do not produce many offspring each year. For example, an elephant is a *K*-selected species because it has a low maximum per capita growth rate as a result of taking 13 years to become reproductively mature, giving birth only once every 2–4 years, and giving birth to only one offspring each time. Such slow reproduction means that elephants have a low maximum per capita rate of growth, so they cannot rapidly increase in population size. Instead, their population remains fairly stable near the environment's carrying capacity.

Species that have evolved rapid reproduction that results in large

fluctuations in population size over time are known as *r*-selected species. These species commonly exhibit a Type III survivorship curve, with a sharp decline in survivorship early in life. For example, in many species of frogs, one female will lay hundreds of eggs that soon hatch into tadpoles. The vast majority of these tadpoles, perhaps as much as 95%, never survive to metamorphose into a frog that will eventually become a breeding adult. In response to such a low probability of surviving to adulthood, these species have evolved high reproductive rates. One result of these high maximum per capita growth rates is that *r*-selected species experience rapid population

increases. If their population exceeds the environment's carrying capacity, the population runs out of food and sharply declines. Thus, *r*-selected species exhibit large variations in population sizes over time. Many species of insects, amphibians, small weedy plants, and small mammals are *r*-selected species. These species typically reproduce early in life, reproduce multiple times in rapid succession, and produce a high number of offspring each time they reproduce. For example, the house mouse (*Mus musculus*) achieves reproductive maturity at 6 weeks of age and then continues to breed again every 5 weeks, producing a dozen offspring with each breeding event.

Review Questions

1. Which statement is true about

population characteristics?

A. Geographic range is the number of individuals divided by the area.
B. Density is the area over which a population is spread.
C. Distribution is the number of males and females in an area.
D. Age structure is the number of individuals in different age categories.

2. Which equation for population growth rate is incorrect?

A. dNdt = N0 − N1 $\frac{dN}{dt} = N_0 - N_1$

B. dNdt = B − D $\frac{dN}{dt} = B - D$

C. dNdt = rmaxN $\frac{dN}{dt} = r_{\max} N$

D. dNdt = D − B $\frac{dN}{dt} = D - B$

3. Which is an assumption of the exponential growth model?

A. Population growth depends on birth rates and death rates.
B. Emigration and immigration occur in the population.
C. Population growth is constrained by limited food.
D. Population breeding happens once each year.

4. Using the exponential growth model, how much will a population increase in 1 year if we begin with 20 individuals and rmax = 0.5 $r_{\max} = 0.5$?

A. 20

B. 10

C. 30

D. 40

5. Which strategy is correctly paired with an evolved characteristic?

A. *K*-selected: slow reproduction

B. *r*-selected: long time to reproductive maturity

C. *K*-selected: fluctuating population sizes

D. *r*-selected: few offspring per reproductive event

Module 53 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–3.

Use the following information to answer question 1.

A bird-watching club collects data about the population densities of two bird species living on an abandoned farm. The first group of bird watchers collects data on the population density of red-winged blackbirds living in field 1 of the farm, while the second group collects data on the population density of robins living in field 2 of the farm. The data collected are listed in the table.

Species	Area (acres)	Number of individuals
Red-winged blackbirds (field 1)	1.7	13
Robins (field 2)	2.5	26

1. Which bird species has a higher population density?

   A. Red-winged blackbirds
   B. Robins
   C. The population densities of both bird species are the same.
   D. The population densities of the bird species cannot be determined from the data provided.

2. Wildlife biologists have reported that female wolves seem to have increased their rates of

reproduction in a Rocky Mountain forest. Which of the following calculations would determine whether the wolf population in this forest is growing at a significantly higher rate than average? Assume that immigration and emigration in the wolf population is negligible.

A. Determining the wolves' population distribution in the forest
B. Determining how many female wolves are of reproductive age in the forest
C. Determining the wolves' population range in the forest
D. Determining the per capita growth rate of the wolves in

the forest

3. Population A of the grey squirrel consists of 55 individuals. After 1 year, population A consists of 58 squirrels. Population B of grey squirrels has 206 individuals and after 1 year its population consists of 222 squirrels. Which population has the greater per capita growth rate?

   A. Population A
   B. Population B
   C. Both populations have the same per capita growth rate.
   D. The per capita growth rate cannot be calculated from the data given.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Ecologists conduct an experiment on the rocky coast of the Atlantic Ocean after a hurricane has removed all the organisms that were attached to the rocks. The ecologists use two identical stretches of the rocky coast to relocate two marine mussel species. Species 1 is introduced to rocky coast 1, and species 2 is introduced to rocky coast 2. The ecologists seed each coast with 10

male and 10 female mussels of the appropriate species. After each generation produces offspring, the ecologists record the number of individuals of each mussel species on each stretch of coast. They collected the data shown in the table.

Generation number	Individuals of species 1	Individuals of species 2
0	20	20
1	34	33
2	58	55
3	98	90
4	167	148
5	284	245
6	483	404
7	821	666
8	1395	1099
9	2372	1813
10	4032	2991
11	6854	4936
12	11,652	8144

13	19,809	13,438
14	33,676	22,172

a. **Draw** a graph that shows the number of generations of the mussels versus the number of individuals in each generation.
b. **Identify** what type of growth model is illustrated by the data of the rocky coast mussel experiment. **Justify** your answer.
c. **Calculate** the number of individuals that will be in generation 15 of species 1.

Module 54

Effect of Density of Populations

Unit	51	52	53	54	55	56	57

LEARNING GOALS

- **LG 54.1 Population growth can be limited by density-independent and density-dependent factors.**
- **LG 54.2 The logistic growth model includes density-dependent population growth.**

In the previous module, we introduced a mathematical model of how populations grow, known as the

exponential growth model. We noted that this model made a number of simplifying assumptions so that we could focus on the core idea that populations can grow exponentially over time, and that this growth is faster in species that possess a high maximum rate of per capita growth (rmax)$(r_{\max})$. The exponential growth model assumes that populations can grow without any limits, which we know is not realistic. In this module, we focus on the factors that place limits on population growth and then modify our mathematical model to incorporate these factors. This will allow us to build a much more realistic model of how populations increase and

decrease in nature.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

54.1 Population growth can be

limited by density-independent and density-dependent factors

The growth of populations can be limited by a number of factors. Some factors can reduce the size of a population regardless of its original size. Other factors have a stronger limiting effect as the population approaches the carrying capacity of the environment. In this section, we will look at these two categories of factors that limit population growth.

Density-independent Factors

When population growth is reduced regardless of its density, we say it is

limited by **density-independent factors.** Common density-independent factors include droughts, extended periods of cold weather, floods, fires, tornadoes, and hurricanes. When these conditions occur, we typically see a drop in birth rates and an increase in death rates, which together cause the population to decline. These declines typically happen quickly, such as when a hurricane strikes an island and immediately kills many of its plants and animals. Similarly, a tornado can quickly rip through a forest and destroy trees, as you can see in **FIGURE 54.1**. The probability of a given tree being destroyed by a tornado is not affected by the number

of other trees around it. With density-independent factors such as a hurricane or a tornado, the magnitude of a population drop is not related to the size of the population. Both large and small populations are equally likely to experience large declines, which means the impacts of these factors are density independent.

FIGURE 54.1 Density-independent population control

Natural disasters such as fires, hurricanes, and tornadoes can substantially reduce populations of plants and animals regardless of the population's density.

A classic study of how density-

independent factors affect population growth was conducted in Australia on an insect known as the apple thrip (*Thrips imaginis*). The apple thrip can be a major pest on fruit trees and rose bushes because it sucks the sap out of leaves, flowers, and fruits, thereby causing damage on the fruits, as shown in **FIGURE 54.2**. When thrips grow to large population sizes, they cause devastating damage on these economically important plants by causing deformed flowers and fruits as they suck the sap out of the plants. Such damage makes it harder for farmers to sell the fruit. Researchers noticed that the size of the thrip population seemed to be driven primarily by temperature and rainfall

during the spring and preceding fall, rather than other factors that are related to population density. In fact, the researchers observed that the insects did not run out of food in the summer, but instead died from droughts that occurred each summer. When they created a mathematical model that included rainfall and temperature—two density-independent variables—they were able to closely predict changes in the thrip population over 15 years in Australia, as shown in **FIGURE 54.3**. In this figure, the blue bars represent the actual size of the thrip population each year while the dashed red line represents the predicted population size when the researchers

incorporated density-independent factors such as temperature and rainfall. Knowing how temperature and rainfall affect the pest populations allowed the ability to predict years of high pest populations, which helped guide the best strategies to control the pests.

FIGURE 54.2 Apple thrips

Apple thrips cause substantial damage on roses and many fruit trees. (a) Thrips suck the sap from leaves, flowers, and fruits. (b) One symptom of thrip damage appears as patches on the fruit.

FIGURE 54.3 Density-independent factors in population growth

Populations of apple thrips in Australia exhibited large fluctuations in size over a

15-year period, as shown by the heights of the bars. Large populations occurred when there was abundant rainfall in the spring and preceding fall. The dashed line represents the predicted population size each year when researchers created a mathematical model of population growth that included density-independent factors, such as temperature and rainfall.

Data from Davidson J., and H. G. Andrewartha. 1948. “The Influence of Rainfall, Evaporation and Atmospheric Temperature on Fluctuations in the Size of a Natural Population of *Thrips imaginis* (*Thysanoptera*).” *Journal of Animal Ecology* 17:200–222.

Density-dependent Factors

When the growth of a population is increasingly limited as its size increases, we say it is subject to **density-dependent factors.** In a classic example of density-dependent factors, Russian biologist Georgii Gause conducted a lab experiment in which he raised two species of single-celled aquatic organisms known as *Paramecium* in test tubes. Each day, he added a constant amount of food and then he tracked the population sizes of the two species for 16 days. As expected from our exponential growth model, both species of *Paramecium* initially experienced

exponential growth. Eventually, however, the population sizes began to plateau as the fixed amount of added food began to limit population growth. You can see the results of Gause's experiment in **FIGURE 54.4a**. In this figure, both species achieve a plateau in their sizes, although the population of *P. aurelia* reaches a higher population size than *P. caudatum*.

FIGURE 54.4 Density-dependent growth in two species of *Paramecium*

Georgii Gause raised the two species under fixed amounts of food. (a) When the two species were raised under a low-food supply, they initially exhibited exponential growth but then leveled off

over time. (b) When the two species were raised under a high-food supply, which contained twice as much food, the populations of the two species once again leveled off over time. However, the leveling off occurred at population sizes that were nearly twice as large as when they were raised under a low-food supply.

Data from Gause, G. F. 1932. “Experimental Studies on the Struggle for Existence: 1. Mixed Population of Two Species of Yeast.” *Journal of Experimental Biology* 9:389–402.

Gause suspected that the populations reached a plateau because food was a limiting factor. To test this hypothesis, he ran a second

experiment in which he doubled the amount of food added to the test tubes each day. When he did this, he found that both *Paramecium* populations once again started with exponential growth but then also leveled off over time. However, this time the populations leveled off at densities that were approximately twice as large as he found in the first experiment, as illustrated in Figure 54.4b.

Gause's experiments are classic because he clearly demonstrated how a limiting resource, in this case food, can limit the size of a population. As the population grows, each individual is competing more intensely for the

limited resource. This competition causes birth rates to go down and death rates to go up until the two offset each other and the population remains stable. As you may recall from the previous module, we refer to this limit on how many individuals can be supported in the environment as the carrying capacity (denoted as K). The carrying capacity is often determined by a limited amount of food, but it can also include other resources, such as a limited number of nesting sites for birds or a limited number of open spots on rocks along an ocean shoreline for barnacles and seaweed to attach. As we will see in the next module, limiting resources combined with predation can cause

predator and prey populations to fluctuate in response to changing carrying capacities over time.

✓ Concept Check

1. **Describe** how density-independent factors limit population size and give an example.

2. **Describe** how density-dependent factors limit population size and give an example.

54.2 The logistic growth model includes density-dependent population growth

Now that we understand how density-dependent factors can constrain population growth by the existence of limited resources, we can begin to examine a modified mathematical model that incorporates the concept of limited resources. To do so, we need to recognize that limited resources set a limit on how many individuals of one species a habitat can support, which is the carrying capacity (K) of the habitat. In this section, we will examine a population growth model that includes the density-dependent effects of the

carrying capacity. We will then examine how populations can overshoot their carrying capacity. Finally, we will examine human population growth and whether there are clear capacities.

The Logistic Growth Model

To incorporate carrying capacity into a mathematical model of population growth, we begin with our exponential growth model that we discussed in the previous module:

$$\frac{dN}{dt} = r_{\max} N$$

d N d t = r max N

As you recall, this model describes an

exponential increase in population sizes over time. To incorporate the idea of a carrying capacity, we need to build on this model by adding some parameters that will slow down population growth as the population increases. We can do this by including the parameter *K,* which is the carrying capacity, and then determining how large a population is relative to the carrying capacity:

d N d t = r max N (K − N K)

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

where:

d t = change in time N = population size r m

$$
\begin{aligned}
dt &= \text{change in time} \\
N &= \text{population size} \\
r_{\max} &= \text{maximum per capita growth rate of population} \\
K &= \text{carrying capacity.}
\end{aligned}
$$

This is the **logistic growth model**, which describes population growth when there is a density-dependent carrying capacity. If we focus on the terms that are in the parentheses, we can see that the value can range from zero to one. When the current population size (N) is much smaller than the carrying capacity (K), the term in the parentheses has a value of approximately one. In this scenario, the few individuals present in the population are experiencing no limits on their population growth, so the model behaves much like our original exponential model. However, when

the current population size (N) approaches the carrying capacity (K), the term in the parentheses has a value of approximately zero, which causes the entire right side of the equation to have a value of approximately zero.

When $\frac{dN}{dt} = 0$, the population is stable, meaning that it is neither increasing nor decreasing; it is at the carrying capacity of the environment. In this scenario, all individuals are severely limited by the available resources to the point that the birth rate is equivalent to the death rate.

When we graph the logistic growth model, we can see the effects of

incorporating carrying capacity. As you can see in **FIGURE 54.5**, the growth of the population follows an S-shaped curve. At the beginning the population grows exponentially. Growth then begins to slow as the effects of a carrying capacity limit population growth over time. Eventually, growth falls to zero. This is the same pattern of growth that we observed in Gause's *Paramecium* experiments. In the middle of this S-shaped curve, the curve has its steepest slope, which is when the growth rate of the population is the fastest. To the right of this midway point, population growth begins to slow. You can see how growth rate (d N d t) $\left(\frac{dN}{dt}\right)$ changes by

working through the calculations presented in "Analyzing Statistics and Data: The Logistic Growth Model."

FIGURE 54.5 Logistic growth model

In the logistic growth model, a population initially experiences exponential growth. As the population continues to grow, the carrying capacity begins to limit the growth because resources become more scarce. This causes an increase in the death rate and a decrease in the birth rate. Once the population reaches the carrying capacity of the environment, the population growth rate stabilizes at zero and the population levels off.

ANALYZING

The Logistic Growth Model

PREP FOR THE AP® EXAM

To understand how the logistic model of population growth produces an S-shaped curve, we can look at an example using a hypothetical population of rabbits.

PRACTICE THE SKILL

In the population, we will set $r_{\max} = 0.5$ and set the carrying capacity at $K = 100$ rabbits. We can then calculate the population's growth rate at several different populations sizes, which tells us how steep the slope of the curve is at different population sizes.

For N = 10 $N = 10$:

d N d t = r max N (K − N K) d N d t = 0.5

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$
$$\frac{dN}{dt} = 0.5 \times 10 \times \frac{100 - 10}{100}$$
$$\frac{dN}{dt} = 5 \times 0.9$$
$$\frac{dN}{dt} = 4.5 \text{ rabbits per year}$$

For N = 20 $N = 20$:

d N d t = r max N (K − N K) d N d t = 0.5

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$
$$\frac{dN}{dt} = 0.5 \times 20 \times \frac{100 - 20}{100}$$
$$\frac{dN}{dt} = 10 \times 0.8$$
$$\frac{dN}{dt} = 8.0 \text{ rabbits per year}$$

For N = 50 $N = 50$:

$dN/dt = r_{max} N (K - N K) dN/dt = 0.5$

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

$$\frac{dN}{dt} = 0.5 \times 50 \times \frac{100 - 50}{100}$$

$$\frac{dN}{dt} = 25 \times 0.5$$

$$\frac{dN}{dt} = 12.5 \text{ rabbits per year}$$

Your Turn

1. Based on the calculations above, determine the population growth rate for $N = 80$ $N = 80$, $N = 90$ $N = 90$, and $N = 100$ $N = 100$.
2. Based on these calculations, what happens to a population's growth rate as it moves from $N = 10$ $N = 10$ to $N = 50$ $N = 50$ and then from $N = 50$ $N = 50$ to $N = 100$ $N = 100$?

AP® EXAM TIP

Make sure you are familiar with the logistic growth model and know how to use the equation $dN/dt = r_{max} N (K - N/K)$

$$\frac{dN}{dt} = r_{max} N \left(\frac{K - N}{K} \right).$$

Population Overshoots and Die-offs

The logistic model suggests that populations approach their carrying capacities very gradually and then become stable. The reality is that populations in nature can often temporarily overshoot their carrying capacity. One reason is that the

carrying capacity of the environment is not fixed from month to month or from year to year. Instead, the environment continues to change so the amount of resources such as food varies over time. This becomes even more problematic in large mammals, which breed in the fall when food might be plentiful but do not give birth until spring, when food may be less abundant. These conditions cause the population to dramatically overshoot the environment's carrying capacity, which means the population now has far more individuals to feed than there is food available. When this happens, we commonly observe a large die-off of the population.

A good example of population overshoot and die-off happened in a population of reindeer that was introduced to St. Paul Island in Alaska in 1920. An initial herd of 25 reindeer was introduced to serve as a food source for the island's residents. Since there was plenty of food available to the reindeer and there were no predators, the population exponentially increased, as you can see in the blue line in **FIGURE 54.6**. If we smooth the trend of the data, as shown in the dashed red line, we see that the population followed a J-shaped curve. By 1938, the herd had grown to nearly 2000 reindeer, which likely far exceeded the island's carrying capacity, and then the

population crashed over the next decade to a low of just 8 animals by 1950. Today, hunting is used to keep the herd at about 400 reindeer, which is much more in line with the island's carrying capacity. While this example shows an extreme case of a population overshooting its carrying capacity and experiencing a subsequent die-off, many other populations experience smaller overshoots and die-offs, such that the population fluctuates above and below the carrying capacity over time.

FIGURE 54.6 Overshoot and die-off in reindeer

In 1910, a herd of 25 reindeer were

introduced to St. Paul Island. The population experienced exponential growth until 1938, when the reindeer experienced a massive die-off, likely as a result of exceeding their carrying capacity. The solid line shows the raw data while the dashed line shows the general trend of the data in producing a J-shaped curve.

Data from Scheffer, V. B. 1951. “The Rise and Fall of a Reindeer Herd.” *Scientific Monthly* 73:356–362.

Predicting Human Population Growth

Given that the growth of many populations in nature follows the

logistic growth model, researchers have been interested in whether human populations also follow the logistic growth model. In the early 1900s, population ecologists were examining U.S. census data from 1790 to 1920. In these census data, the researchers noticed that the U.S. population had exponentially increased in size from 1790 to 1910, but by 1920 the population growth was starting to slow down. Since this pattern closely matched the pattern expected by the logistic growth model, the researchers could estimate that the population in 1910, which was 91 million people, must be about half of the country's carrying capacity. As a result, they used the

model to predict that the U.S. carrying capacity was 197 million people, as shown in the black dashed line in **FIGURE 54.7**.

FIGURE 54.7 Human population growth in the United States

Based on U.S. census data from 1790 to 1920, researchers in 1920 used the logistic growth model to predict the carrying capacity of the United States. Their prediction of $K = 197$ $K = 197$ million people has been greatly exceeded as a result of increased food production in the United States and increased imports of food from around the world.

Data from Pearl, R., and L. J. Reed. 1920. “On the Rate of Growth of the Population of the

United States since 1790 and Its Mathematical Representation." *Proceedings of the National Academy of Sciences* 6:275–288; U.S. Census Bureau, http://2010.census.gov/2010census/data/apportionment-pop-text.php.

While this carrying capacity was a reasonable prediction in the early 1900s, the U.S. population has far exceeded this prediction, as shown by the red data points in Figure 54.7, with a population of 331 million people in 2020. One of the reasons that the estimated carrying capacity has been far exceeded is that U.S. farmers have more advanced technologies to produce much more

food per hectare than they did 100 years ago. In addition, the researchers were estimating the U.S. carrying capacity based on the assumption that the population could only consume food produced in the United States. However, the modern reality is that the United States imports a great deal of food from other countries, which further increases the number of Americans that can be fed. In addition to these increases in carrying capacity, the rate of population growth has been further increased by medical advances that have dramatically reduced human death rates and by the number of immigrants that have come to the United States.

✓ Concept Check

3. **Describe** how the logistic model of population growth builds on the exponential model.

4. **Describe** the pattern of population growth rate over time in the logistic model.

5. **Identify** what happens when a population overshoots its carrying capacity.

Review Questions

1. Which is a density-dependent factor for populations?

    A. Hurricane

    B. Flood

    C. Fire

    D. Limited food

2. Which is an expectation of a population exhibiting density-independent growth?

    A. There is a resource in limited

supply.

B. Small populations will initially experience rapid growth.

C. Large populations can still experience rapid growth.

D. There is a carrying capacity that regulates population growth rate.

3. In the logistic growth model, how do birth rates compare to death rates when the population is small versus when the population is at carrying capacity?

A. Birth rates = death rates; Birth rates > d

Birth rates = death rates; Birth rates > death rates

B. Birth rates > death rates; Birth rates < d

Birth rates > death rates; Birth rates < death rates

C. Birth rates = death rates; Birth rates < d

Birth rates = death rates; Birth rates < death rates

D. Birth rates > death rates; Birth rates = d

Birth rates > death rates; Birth rates = death rates

4. Which statement is true about population overshoots?

A. They can occur because carrying capacity can change over time.
B. They can occur because most populations do not have carrying capacities.
C. They can occur because most populations do not experience limiting resources.
D. They can occur when death rates are exceeding birth rates.

5. Which assumption informed the

prediction that the U.S. population would plateau at 197 million people?

A. The United States would import large amounts of food.
B. The United States had a limited carrying capacity for feeding people.
C. The United States would increase its human carrying capacity over time.
D. The United States would have substantial immigration.

Module 54 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice

Questions

Choose the best answer for questions 1–4.

Use the following information to answer questions 1 and 2.

Foxes eat a variety of foods, including rabbits and mice. Rabbits eat plants, and mice eat the seeds of plants. Ecologists studying foxes in a prairie ecosystem note that after a particularly rainy spring there was an increase in the prairie grass population and then an increase in the mouse population. During the following summer and fall there was an increased abundance in the fox and rabbit populations.

1. Which of the following statements correctly describes the effect of the grass on the mouse and rabbit populations?

   A. The increased grass population was a density-independent factor for mice, but a density-dependent factor for rabbits.
   B. The increased grass population was a density-dependent factor for mice but a density-independent factor for rabbits.
   C. The increased grass population was a density-dependent factor for mice and rabbits.
   D. The increased grass population was a density-independent factor for mice and rabbits.

2. Which of the following statements correctly describes the effects of the mouse and rabbit populations on the fox population?

   A. The increase in mice was a density-dependent factor for the fox population.
   B. The increase in mice was a density-independent factor for the fox population.
   C. The increase in mice was neither a density-dependent factor nor a density independent-factor for the fox population.
   D. The increases in mice and rabbits were density-independent factors for the fox

population.

3. A population of gophers has 1000 individuals with an *rmax* $r_{\max}$ of 0.4 per year and a carrying capacity of 975 gophers. What will be the gopher population size after 2 years? (Use whole numbers in your calculation.)

   A. The population will be 1000 gophers.
   B. The population will be 1008 gophers.
   C. The population will be 984 gophers.
   D. The population will be 990 gophers.

Use the following figure to answer

question 4.

1. The figure depicts the carrying capacity and the population size of an animal species over time. Which of the following best explains why the population size fluctuates less widely with time and reaches the carrying capacity?

   A. The population runs out of food and stops breeding.
   B. The population is no longer subjected to density-dependent factors.
   C. New inputs of resources allow the population to grow at a

more uniform rate.

D. Over time, the population experiences smaller overshoots and die-offs.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

The data shown in the following graph were collected for the species *Euglena gracilis,* which is a single-celled alga. Cultures of *E. gracilis* were provided with inorganic nutrients, such as nitrogen and phosphate, and

the experiment was conducted for 10 days in multiple vessels that could accommodate population sizes 10 times larger than the population sizes observed. To begin the experiment, *E. gracilis* cells were added to the water-based medium containing the nutrients and the vessels were free of competitors, predators, and pathogens. The quantity of light was constant and not growth-limiting. As shown in the following graph, scientists recorded the population size each day and the data from the multiple vessels were averaged.

a. **Predict** how the population size would change by day 20 if, on the

10th day, the population is given two times as many nutrients as was done at the beginning of the experiment. **Justify** your answer.

b. **Determine** the carrying capacity (K) of the *Euglena* for the first 10 days of this experiment.

c. The scientists conducted the experiment a second time, but this time the amount of light shone on the *E. gracilis* was limiting. The results of this second experiment are shown in the following figure. **Predict** how the carrying capacity of the *Euglena* population would change by day 20 if the researchers reduced the amount of light shining on the growth vessel by

50% on the 11th day of the study.

Justify your answer.

Tutorial 3: Rate and Growth in Population Ecology

PREP FOR THE AP® EXAM

As we saw in Module 53, populations fluctuate over time. Biologists interested

in understanding population growth might ask questions about why some populations experience rapid or slow growth over time, or why populations have small or large fluctuations in size over time. Analyzing population growth and fluctuations requires the use of two mathematical models that we will review in this tutorial: the exponential growth model and the logistic growth model.

Population Growth

If we assume that a population experiences no immigration or emigration, then population growth is determined by the number of births and deaths occurring in that population. If the number of births is greater than the number of deaths, then that population will increase in size. If the number of

deaths is greater than the number of births, the opposite is true and the population will decrease in size. Thus, the change in population size over time is:

$$\frac{dN}{dt} = B - D$$

d N d t = B − D

where:

d N d t = the change in population size over

$\frac{dN}{dt}$ = the change in population size over time

N = population size

dt = change in time

B = birth rate (number of births over time)

D = death rate (number of deaths over time)

Your Turn

A population experienced a birth rate of 7 individuals per month and a death rate of 4 individuals per month. What was the change in population size that year?

Solution

In this example, we see that the birth rate, *B,* is 7 and the death rate, *D,* is 4.

$$\mathrm{d\,N\,d\,t = B - D\,d\,N\,d\,t = 7\ individuals\ per}$$

$$\frac{dN}{dt} = B - D$$

$$\frac{dN}{dt} = 7 \text{ individuals per month} - 4 \text{ individuals per month}$$

$$\frac{dN}{dt} = 3 \text{ individuals per month}$$

The result tells us that this population increased in size by 3 individuals per month. We know this change was an increase because the birth rate is larger than the death rate and the result is a positive number. If the answer had been -3 -3, that would indicate that the death rate is larger than the birth rate, causing a decrease in population size by 3 individuals.

The question asks us to determine the change in population size that year. To answer this, we can multiply the change

in individuals per month by 12, the number of months in a year: $3 \times 12 = 36$ $3 \times 12 = 36$. The population increased by 36 individuals that year.

▶ See "Analyzing Statistics and Data: Population Growth," which provides an opportunity to practice these concepts in context.

Per Capita Population Growth

While the above simple model of population growth rate considers the birth rate and death rate of a population, it does not tell us how birth and death rates change as the population changes in size. For example, a large population has the potential for many more births, and therefore a higher birth rate, because it has many

more breeding individuals. As a result, we need to understand the growth rate of each individual, which we refer to as the per capita growth rate (*r*). The per capita growth rate is calculated as follows and can be written one of two ways:

$$r = dN\,dt \div N \quad \text{or} \quad r = B - DN$$

$$r = \frac{dN}{dt} \div N \text{ or } r = \frac{B - D}{N}$$

where:

$$r = \text{per capita growth rate}\ dN\,dt = \text{the cha}$$

r = per capita growth rate

$\frac{dN}{dt}$ = the change in population size over time or rate of population change

N = population size

As you can see in these equations, per capita growth is the rate of population change divided by the number of individuals in a population. If *r* is positive, the birth rate exceeds the death

rate and the population is increasing. If r is negative, the death rate exceeds the birth rate and the population is decreasing. It is important to take note of the magnitude of the per capita growth rate as well. When r is a large number, the population is increasing or decreasing rapidly. A smaller r value indicates a slower rate of change. A growth rate of 0 indicates that the population is neither increasing nor decreasing. The population size is stable and unchanging because the birth rate offsets the death rate.

The Exponential Growth Model

Knowing the per capita growth rate and the current size of a population allows us to predict future population growth using the exponential growth model:

$$\frac{dN}{dt} = r_{\max} N$$

d N d t = r max N

where:

d N d t = the change in population size over

$\frac{dN}{dt}$ = the change in population size over time or rate of population change
$r_{\max}$ = the maximum per capita growth rate
N = population size

We call this the exponential growth model because if $r > 0$ $r > 0$, the population will grow exponentially. This model assumes that the population does not experience immigration or emigration; that births and deaths occur continuously throughout the year; and that there are no environmental constraints on growth, such as limited food or space. These assumptions are not very realistic in nature, but they provide us with an initial model that we can subsequently modify.

As shown in the following graph, the exponential growth model is represented by a J-shaped curve. At the beginning of the time period, a population grows slowly because there are not many individuals. This is shown by the flat portion of the curve. Over time, as there are more individuals in the population, the population increases rapidly. This increase is represented by a J-shaped curve. Because there are no limitations or constraints acting on the population, individuals will continuously be added to the population at an increasingly fast rate.

Your Turn

A population of fruit flies is experiencing

exponential growth. The population size is 100 flies.

1. What is the size of this population of fruit flies one month from now if $r_{\max} = 0.15$?
2. What is the size of this population of fruit flies one month from now if $r_{\max} = 0.5$?

Solution

1. We will use the exponential growth model to answer both questions.

$$\mathrm{d\,N\,d\,t = r\,max\,N\,d\,N\,d\,t = 0.15 \times 100\,d\,N}$$

$$\frac{dN}{dt} = r_{\max} N$$

$$\frac{dN}{dt} = 0.15 \times 100$$

$$\frac{dN}{dt} = 15 \text{ flies per month}$$

Thus, the fly population will increase by 15 additional flies in one month, so the

population increases from 100 to 115 flies.

2. In the second example, the population is still 100 flies, but $\mathrm{r\ max\ =\ 0.50}$ $r_{\max} = 0.50$.

$$\mathrm{d\ N\ d\ t\ =\ r\ max\ N\ d\ N\ d\ t\ =\ 0.5\ \times\ 100\ d\ N}$$

$$\frac{dN}{dt} = r_{\max} N$$

$$\frac{dN}{dt} = 0.5 \times 100$$

$$\frac{dN}{dt} = 50 \text{ flies per month}$$

In this case, the fly population will increase by 50 additional flies in one month, so the population increases from 100 to 150 flies.

▶ See "Analyzing Statistics and Data: Exponential Growth," which provides an opportunity to practice these concepts in context.

The Logistic Growth Model

The exponential growth model is useful for determining changes in size when there are no limitations on population growth. However, this is not typical in nature. Populations may experience a variety of limitations on growth, including limited food and space. When the environment limits population growth, we can modify our exponential growth model to create the logistic growth model. This model includes a term that slows down population growth as the population approaches the carrying capacity (K) of the environment, which is the maximum number of individuals that can be supported in the environment.

The following graph shows that logistic

growth is depicted by an S-shaped curve. Early on, the population experiences exponential growth. Growth is fastest at the middle of the S. However, as the population grows, competition increases as resources become scarcer. This causes population growth to slow and the population experiences a rising death rate and falling birth rate. As the population reaches the carrying capacity, the growth rate stabilizes and birth and death rates offset each other. At this point, the population growth rate is zero.

We can understand how the population's growth rate changes with an increasing population size by

examining the formula for the logistic growth model:

$$\mathrm{d\,N\,d\,t} = \mathrm{r\,max\,N\,(\,K} - \mathrm{N\,K\,)}$$

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

where:

$$\mathrm{d\,N\,d\,t} = \text{the change in population size over}$$

$\frac{dN}{dt}$ = the change in population size over time or rate of population change
$r_{\max}$ = max per capita growth rate
N = population size
K = carrying capacity

As you can see, the logistic growth model resembles the exponential model, but it contains terms in the parentheses that cause the population to slow its growth as the number of individuals approaches the carrying capacity.

If the population size is much smaller than the carrying capacity, then the

term $(K - N K)$ $\left(\frac{K-N}{K}\right)$ has a value of approximately 1. This means that the small number of individuals in the population are not experiencing any limits on their growth and the model behaves like the exponential model. This is seen by plugging a 1 into the logistic growth model for $K - N K$ $\frac{K-N}{K}$. The result is the formula for the exponential model:

$$d N d t = r \max N (K - N K) d N d t = r m$$

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K-N}{K}\right)$$

$$\frac{dN}{dt} = r_{\max} N \times 1$$

$$\frac{dN}{dt} = r_{\max} N$$

If the population size is approaching the carrying capacity, then the

term $(K - N K)$ $\left(\frac{K-N}{K}\right)$ has a value of approximately 0. This means that the large number of individuals in the population are experiencing harsh limits on their growth due to lessening resource availability. At this point, the birth rate and the death rate are equal, so the population size is stable at the carrying capacity of the environment.

Your Turn

Georgii Gause's experiments provide a great example of the logistic growth model. We can examine the growth rate of a *Paramecium* population over 10 days at a few different population sizes to see how the growth rate changes.

Calculate the logistic growth rate for population sizes of 25, 100, and 190 individuals, given a maximum per capita

growth rate of 1.0 and a carrying capacity of 200. Explain what each growth rate means in terms of the population size.

Solution

To begin, we can see that we have all of the variables needed to use the logistic model formula. We can proceed to plug them in, one population size at a time. It will also be useful to examine each population point on a logistic curve graph to visualize the change in growth rate.

N = 25 : d N d t = r max N (K − N K) d N

$N = 25$

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

$$\frac{dN}{dt} = 1 \times 25 \times \left(\frac{200 - 25}{200} \right)$$

$$\frac{dN}{dt} = 22 \text{ individuals per day}$$

When the population is at 25 individuals, it is much smaller than the carrying capacity of 200 individuals. As a result, the population is not limited by food. With a growth rate of 22 individuals per day, the population is nearly doubling in size. You can see this growth rate identified at the bottom of the S-curve, where it is just starting to rise.

N = 100 $N = 100$

d N d t = r max N (K − N K) d N d t = 1 ×

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

$$\frac{dN}{dt} = 1 \times 100 \times \left(\frac{200 - 100}{200} \right)$$

$$\frac{dN}{dt} = 50 \text{ individuals per day}$$

When the population is at 100

individuals, it is halfway to the carrying capacity of 200 individuals. The population is still not limited by food and with a growth rate of 50 individuals per day, the population is rapidly increasing. You can see this growth rate identified near the middle of the S-curve.

N = 190 $N = 190$

d N d t = r max N (K − N K) d N d t = 1 ×

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

$$\frac{dN}{dt} = 1 \times 190 \times \left(\frac{200 - 190}{200} \right)$$

$$\frac{dN}{dt} = 10 \text{ individuals per day}$$

When the population is at 190 individuals, it is approaching the

carrying capacity of 200 individuals. The population is now limited by food, and the growth rate has slowed to 10 individuals per day. The population is slowly stabilizing to the point where the birth and death rates will be equal. You can see this growth rate identified near the top of the S-curve.

▶ See "Analyzing Statistics and Data: The Logistic Growth Model," which provides an opportunity to practice these concepts in context.

Let's now look at a problem that compares the exponential growth model and the logistic growth model.

Your Turn

A group of scientists is growing a

population of bacteria in the laboratory with a fixed amount of food. If $\mathrm{r\ max}$ $r_{\max}$ is 0.9 per hour and the carrying capacity for the bacteria is 500 individuals:

1. Calculate the growth rate for the exponential growth model when *N* is 64 and when *N* is 450.
2. Calculate the growth rate for the logistic growth model when *N* is 64 and when *N* is 450.
3. Compare and contrast the results given by each model.
4. Which of these models better represents the bacterial colony that the scientists are cultivating and why?

Solution

1. Let's start by calculating the

exponential growth rates:

$N = 64$ $N = 64$

$dN/dt = r_{max} N$ $dN/dt = 0.9 \times 64$ dN/d

$$\frac{dN}{dt} = r_{\max} N$$
$$\frac{dN}{dt} = 0.9 \times 64$$
$$\frac{dN}{dt} = 57.6 \text{ bacteria per hour}$$

$N = 450$ $N = 450$

$dN/dt = r_{max} N$ $dN/dt = 0.9 \times 450$ dN

$$\frac{dN}{dt} = r_{\max} N$$
$$\frac{dN}{dt} = 0.9 \times 450$$
$$\frac{dN}{dt} = 405 \text{ bacteria per hour}$$

The exponential model shows that at a population size of 64, the number of bacteria added in the subsequent hour is 58. At $N = 450$ $N = 450$, that number

has increased dramatically to 405 bacteria per hour. With the exponential growth model, the size of the population continues to increase because population growth does not have environmental constraints.

2. Now let's calculate the logistic growth rates:

N = 64 $N = 64$

d N d t = r max N (K − N K) d N d t = 0.9

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$

$$\frac{dN}{dt} = 0.9 \times 64 \times \left(\frac{500 - 64}{500} \right)$$

$$\frac{dN}{dt} = 50 \text{ bacteria per hour}$$

N = 450 $N = 450$

d N d t = r max N (K − N K) d N d t = 0.9

$$\frac{dN}{dt} = r_{\max} N \left(\frac{K - N}{K} \right)$$
$$\frac{dN}{dt} = 0.9 \times 450 \times \left(\frac{500 - 450}{500} \right)$$
$$\frac{dN}{dt} = 41 \text{ bacteria per hour}$$

The logistic model shows that at a population size of 64, the number of bacteria added in the subsequent hour is 50. The population size is still far from reaching the carrying capacity and is experiencing rapid growth. At 450 bacteria, the growth rate slows to 41 bacteria per hour, and will further slow down as the population continues to approach the carrying capacity.

3. Although both models begin with nearly the same rapid growth (58 bacteria per hour compared to 50 bacteria per hour), we can see that as the population continues to increase to

450 individuals, the exponential and logistic rates differ greatly (405 bacteria per hour compared to 41 bacteria per hour). This shows the inherent differences between the models. When there are no environmental constraints, the population is free to expand and increase indefinitely. However, if there are food or space limitations, the logistic model shows that population growth will eventually slow as it reaches the carrying capacity.

4. Because the scientists are growing the bacteria in laboratory conditions with a fixed amount of food, the scientists are imposing a carrying capacity on the population. As a result, it is likely that the logistic model better reflects the growth rates occurring in the lab.

The two growth models reviewed in this tutorial each have their own specified uses, but all are valuable in determining population growth. The exponential growth model, although it has simplifying assumptions, is useful in introducing us to predicting how populations grow over time, particularly when small populations are far from their carrying capacity. Realistically, populations do not normally undergo indefinite, exponential growth because of the natural constraints that they experience. The logistic growth model accounts for these constraints and offers us a more realistic course of how populations may grow in the future.

Module 55

Community Ecology

Unit	51	52	53	54	55	56	57

LEARNING GOALS

- **LG 55.1 Community structure includes species diversity and distinct niches.**
- **LG 55.2 Community structure also includes a diverse set of species interactions.**
- **LG 55.3 Species interactions cause direct and indirect effects in communities.**
- **LG 55.4 Communities experience disturbances that cause changes in**

species abundance and composition.

In the previous module, we focused on populations and how they increase and decrease over time in relation to their carrying capacities. Now it is time for us to move up a level of complexity to think about communities, which we defined as all the interacting species that live in a given area. In doing so, we want to understand how communities are structured in terms of species diversity, considering both the number of species and number of individuals comprising each species. We can also think of community structure in terms of the habitats and niches that species occupy.

Communities are also structured in terms of how species interact with each other—including predation, herbivory, and competition—and how this helps us understand the flow of energy throughout the food web. Finally, we can examine how disturbances can dramatically alter the composition and abundance of species in a community and how this composition can change over time.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

ENERGETICS: Consider how the availability of energy resources in the environment affects interactions

among populations in a community.

55.1 Community structure includes species diversity and distinct niches

In this section, we begin by discussing how we quantify the

diversity of species in a community. We then discuss why a given species lives where it does and why it does not live elsewhere. In doing so, we will distinguish between a habitat and a species' niche.

Species Diversity and Richness

At the species level, biodiversity refers to the variety of genotypes, species, or ecosystems present in an area. When biologists quantify biodiversity, they consider both the number of species, which we refer to as species richness, and the number of individuals representing each species, which we refer to as species

evenness. As a result, if two communities both have similar evenness, the one with more species is considered to be more diverse. In addition, if two communities have a similar number of all species, the one with a similar percentage of individuals among all species is considered to be more diverse than a community with one very abundant species. For example, consider two areas with four species of trees, as illustrated in **FIGURE 55.1**. The two areas have the same species richness, but community 1 has high species evenness while community 2 has low species evenness, with one species comprising 70% of all trees. Therefore, community 1 is considered

more diverse than community 2.

FIGURE 55.1 Comparing species richness and evenness

The two tree communities both have four species, so they have the same species richness. However, the two communities differ in species evenness, with community 1 having high evenness, with each tree species comprising 25% of the trees, while community 2 has low evenness, with one tree species comprising 70 of the trees.

A common way to quantify the diversity of species in a community is to use an index created by Edward Simpson, which we call **Simpson's**

diversity index. Simpson's diversity index incorporates both the number of species in a community and the relative proportion of individuals within each species, which represents a measure of evenness. Using this index, a higher value indicates a more diverse community. To calculate the index, we list the species found in a community and determine the total number of organisms of a particular species (n). By summing all individuals across all species, we can determine the total number of organisms of all species (N). With these data, we can calculate Simpson's diversity index (D) using the following formula:

$$\text{Diversity index} = 1 - \Sigma \left(\frac{n}{N} \right)^2$$

$$\text{Diversity index} = 1 - \Sigma \left(\frac{n}{N} \right)^2$$

where:

n = the total number of organisms of a particular species

N = the total number of organisms of all species

n = the total number of organisms of a particular species
N = the total number of organisms of all species

In this equation, you can see that the value in the parentheses represents the percentage of individuals that comprise a given species. We then square this percentage and sum the squared percentages for all the species in a community.

As an example, consider **TABLE 55.1**, which contains data on the abundance of mammals in three

different communities.

Species	Communit A abundanc	Communit B abundanc	Community C abundance
Mouse	50	20	
Chipmunk	30	30	
Squirrel	10	30	
Shrew	5	20	
Vole	5	20	
Total abundance	100	100	

TABLE 55.1 The Abundance of Different Mammal Species in Three Communities

We will begin by calculating Simpson's diversity index for community A:

D = 1 − [(50 100) 2 + (30 100) 2 + (1

$$D = 1 - \left[\left(\frac{50}{100}\right)^2 + \left(\frac{30}{100}\right)^2 + \left(\frac{10}{100}\right)^2 + \left(\frac{5}{100}\right)^2 + \left(\frac{5}{100}\right)^2\right]$$

$$D = 1 - [0.25 + 0.09 + 0.01 + 0.0025 + 0.0025]$$

$$D = 1 - [0.355]$$

$$D = 0.645$$

Now we can do the same set of calculations for community B, which has the same number of species as community A, but greater evenness:

D = 1 − [(20 100) 2 + (20 100) 2 + (2

$$D = 1 - \left[\left(\frac{20}{100}\right)^2 + \left(\frac{20}{100}\right)^2 + \left(\frac{20}{100}\right)^2 + \left(\frac{20}{100}\right)^2 + \left(\frac{20}{100}\right)^2\right]$$

$$D = 1 - [0.04 + 0.04 + 0.04 + 0.04 + 0.04]$$

$$D = 1 - 0.20$$

$$D = 0.80$$

Finally, we can do the same set of calculations for community C, which has high evenness but a lower species richness:

D = 1 − [(34 100) 2 + (33 100) 2 + (3

$$D = 1 - \left[\left(\frac{34}{100}\right)^2 + \left(\frac{33}{100}\right)^2 + \left(\frac{33}{100}\right)^2\right]$$

$$D = 1 - [0.116 + 0.109 + 0.109]$$

$$D = 1 - 0.33$$

$$D = 0.67$$

As you can see in these three examples, Simpson's diversity index produces a higher value for communities that have a higher species richness and for communities that have a higher species evenness. Thus, the index provides us with an objective way to compare the species diversity of different communities, such as communities in different parts of the world or communities that change in their abundance of species over time. For review and practice of Simpson's diversity index, see "Analyzing Statistics and Data: Simpson's Diversity Index."

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should know how to calculate Simpson's diversity index and you should understand what the calculated numbers say about the degree of diversity in a community.

ANALYZING STATISTICS AND DATA

Simpson's Diversity Index

PREP FOR THE AP® EXAM

Biologists often want to measure the biodiversity of species living in a community, such as in a forest, field, or pond. We can calculate the diversity of species in communities using a model known as Simpson's diversity index. This model incorporates both species richness (the number of species) and

species evenness (the number of individuals representing each species) to quantify diversity. As we saw in the discussion above, the formula is:

$$\text{Diversity index} = 1 - \Sigma\,(\,\mathrm{n}\ \mathrm{N}\,)\ 2$$

$$\text{Diversity index} = 1 - \Sigma\left(\frac{n}{N}\right)^2$$

where:

$$\mathrm{n} = \text{the total number of organisms of a parti}$$

n = the total number of organisms of a particular species
N = the total number of organisms of all species

A high diversity index value indicates a more diverse community due to either greater species richness or greater species evenness. The diversity index can range from 0 to 1, where 0 is a completely uniform community and 1 is a completely diverse community.

PRACTICE THE SKILL

A team of researchers has conducted a survey of the trees in a plot of land in Yellowstone National Park. Twenty years earlier, this plot was heavily dominated by the lodgepole pine tree and the diversity index was 0.44. The team wishes to know if the diversity in this area has increased, decreased, or remained the same. They collected the following data from their survey of tree species:

Tree species	Abundance
Lodgepole pine	738
Douglas fir	192
Whitebark pine	261
Englemann spruce	313

Calculate the diversity index for this plot of land and compare it to the diversity index from previous years.

To begin, we can assess which variables we have and which we need to find in order to use the diversity index formula. We have the number of each individual tree species surveyed by the researchers, *n,* but we must find the total number of all tree species, *N*. This is done simply by adding up each species:

$$\mathrm{N} = 738 + 192 + 261 + 313 = 1504 \text{ total}$$

$N = 738 + 192 + 261 + 313 = 1504$ total trees

With this, we can use Simpson's diversity index formula to calculate the diversity of this plot of land. Remember that the sigma sign indicates that we must sum the abundance of each tree species, divided by the total number of trees.

$$\mathrm{D} = 1 - \Sigma\,(\,\mathrm{n}\ \mathrm{N}\,)\ 2\ \mathrm{D} = 1 - [\,(\,738\ 1504\ )$$

$$D = 1 - \Sigma\left(\frac{n}{N}\right)^2$$
$$D = 1 - \left[\left(\frac{738}{1504}\right)^2 + \left(\frac{192}{1504}\right)^2 + \left(\frac{261}{1504}\right)^2 + \left(\frac{313}{1504}\right)^2\right]$$
$$D = 1 - (0.241 + 0.016 + 0.030 + 0.043)$$
$$D = 0.67$$

Thus, in the present day, the diversity index of this Yellowstone plot of land is 0.67. Compared to the diversity index of 0.44 in the past, it appears that the forest has become more diverse. The table shows that the lodgepole pine is still the most abundant tree species in this forest, but over time, the abundance of the other species must have increased as well. The higher Simpson's diversity index value indicates that while there has not been an increase in species richness, there has been an increase in species evenness.

Your Turn

Two neighbors living in the

northwestern United States decided to begin growing gardens of various wildflowers in their yards in order to attract more pollinators. After several months of growth, they tallied the number of plants of each species to compare the communities. The results are shown in the table. Calculate Simpson's diversity index for each garden to determine which neighbor has a more diverse community of flowers. How do the species richness and evenness of the two gardens compare?

Wildflower species	Neighbor 1 abundance	Neighbor 2 abundance
Scabland penstemon	20	
Rocky Mountain bee plant	88	
Bluebell	26	
White clover	67	
Bulbous buttercup	66	
Woods rose	24	
Common agrimony	28	

Canada wood sorrel	19	
Total flowers	260	

Habitat

A habitat is the physical setting where a species lives. For example, the eastern cottontail rabbit (*Sylvilagus floridanus*) lives in fields throughout eastern North America whereas the moose (*Alces alces*) lives in the deciduous and coniferous forests of Alaska, Canada, the Rocky Mountains, and New England. We typically categorize terrestrial habitats in terms of the dominant plant life that is driven by regional temperature and precipitation, such as tropical grasslands, tropical rainforests, forests, and deserts. In

contrast, we categorize aquatic habitats in terms of whether there is salt water or fresh water and whether the water is flowing, such as oceans, lakes, and streams.

Niche

As we discussed in Module 47, a species' niche is a complete description of the role the species plays in its environment and the abiotic and biotic requirements that allow a species to survive, grow, and reproduce. It is helpful to think of the niche in terms of the abiotic conditions a species requires and how interactions with other species may help or hinder a species from

persisting in an area.

The abiotic conditions that a species requires are determined by its range of tolerance to different conditions. For example, different species have a specific range of optimal temperatures, as shown in **FIGURE 55.2**. At its optimal temperature range, individuals in the species can survive, grow, and reproduce. Above and below the optimal temperature range, the species can survive, but not grow and reproduce, because the high or low temperatures are too stressful. Of course, temperature is just one of many abiotic conditions for which a species has an optimal range of tolerance. Other abiotic

conditions that affect a species can include pH, nutrients, salinity, oxygen concentrations, and water availability. The full suite of abiotic conditions that allows a species to survive, grow, and reproduce is its fundamental niche.

FIGURE 55.2 Range of tolerance

Temperature provides an example of range of tolerance. A species has an optimal temperature range under which it can survive, grow, and reproduce. As temperatures move above and below the optimal temperature, the species loses the ability to reproduce. Under even more extreme temperatures, the species can no longer grow and eventually cannot even survive.

Although the fundamental niche tells us the abiotic conditions under which a species can live, most species do not live everywhere those ideal conditions are found. The reason is because species also have to deal with biotic conditions, such as the presence of predators or competitors, which can prevent the species from persisting in a particular area. The combination of abiotic and biotic conditions under which a species survives, grows, and reproduces is its realized niche.

The red-winged blackbird (*Agelaius phoeniceus*) provides an example of

the difference between a fundamental niche and a realized niche. The red-winged blackbird is a common bird that prefers to nest in vegetation that sticks above the water surface of marshes, including both shallow and deep water, as illustrated in **FIGURE 55.3a**. However, if yellow-headed blackbirds (*Xanthocephalus xanthocephalus*) are present, they drive the red-winged blackbirds away from the nesting locations in the middle of the marsh, which have the deepest water. In doing so, they displace the red-winged blackbirds to a realized niche that includes nesting sites around the shallow edges of the marsh, as shown in Figure 55.3b. This example illustrates that the realized

niche is often smaller and more restricted than the fundamental niche.

FIGURE 55.3 Fundamental and realized niches

While fundamental niches include the range of abiotic conditions in which a species can live, interactions with other species can further restrict where a species actually lives. (a) When the red-winged blackbird is by itself, it occupies all appropriate nesting sites in the vegetation that emerges from a marsh, from the shallow water along the edge to the deep water in the middle. This represents its fundamental niche. (b) If yellow-headed blackbirds arrive, they drive the red-winged blackbirds out of

the nesting sites with the deepest water, so the realized niche of the red-winged blackbird becomes only the shallow-water nesting sites.

When we compare the niches of different species, we find that some species are considered niche generalists because they can live under a wide range of abiotic and biotic conditions. For example, the gray kangaroo (*Macropus giganteus*) eats a wide range of different plant species, so it is a niche generalist. Other species are considered niche specialists because they only live under a very narrow range of conditions. For example, the panda

(*Ailuropoda melanoleuca*) only eats bamboo and not any other plants. Being a niche specialist can be beneficial when a food source is highly reliable throughout the year and year after year. Often the specialist evolves adaptations that make it particularly effective at consuming and digesting one type of food. In contrast, being a niche generalist allows a species to persist as the environment changes over time, such as seasonal changes in the types of food that are available. If some food items are no longer available, the generalist can persist by eating many other food sources. However, the niche specialist faces a major problem if its food sources

decline as the environment changes, placing it at an increased risk of future extinction.

✓ Concept Check

1. **Describe** the measures of species diversity that go into Simpson's diversity index.

2. **Describe** the difference between a fundamental niche and realized niche.

3. **Describe** the difference between a niche generalist and niche specialist.

55.2 Community structure also

includes a diverse set of species interactions

While a community includes all the species that are interacting within a given area, there are many different ways in which these species can interact. These interactions determine how energy and matter flow in communities among the producers and consumers. Interactions between species can cause negative effects, positive effects, or neutral effects on the populations of these species. As we will see, some of these interactions involve a symbiosis, in which two species live in close proximity.

Predation

Predation is an interaction that involves one species killing another and consuming it. Predation is common in nature, such as lions killing gazelles on an African savanna, grizzly bears catching salmon in a river, and woodpeckers eating insects living in dead trees. Predators can have a large impact on the populations of their prey and their effect sometimes causes predator and prey populations to cycle up and down.

One of the best examples of predator and prey populations cycling involves the Canada lynx (*Lynx canadensis*) as a

predator and the snowshoe hare (*Lepus americanus*) as the prey. Beginning in the mid 1800s, both of these species were prized for their pelts and the Hudson Bay Company in Canada would buy the pelts from trappers, so we have a nearly 100-year record of when each species was abundant and when each species was rare. When the ecologist Charles Elton graphed the trapping data, he was struck by the pattern of cycles, which is shown in **FIGURE 55.4**. As you can see in the figure, the lynx and hare populations cycled between high and low numbers about every 10 years. In addition, the cycling of the lynx population lagged behind the cycling of the hare population by 1-2

years.

FIGURE 55.4 Population cycles of lynx and hares in Canada

Based on records of pelts purchased from trappers by the Hudson Bay Company, lynx and hare populations cycle up and down about every 10 years. In addition, the lynx population shows a 1- to 2-year lag in its response compared to the hare population.

Data from: MacLulich, D. A. 1937. *Fluctuations in the Number of the Varying Hare (Lepus americanus).* University of Toronto Studies, Biological Series No. 43.

The hare cycling is caused by changes in the abundance of vegetation that

they eat, while the lynx cycling is caused by changes in the size of the hare population. When the hare population is low, the plants they eat have an opportunity to grow more because there are fewer hares to eat them. The increase in the vegetation allows the hare population to increase exponentially over several years. As the hare population grows, more hares are available for the lynx to eat. The abundance of food allows the lynx population to begin increasing its birth rates and decrease its death rates, which causes an exponential increase in the lynx population, albeit with a lag time between the increasing hare population and the resulting increase in the lynx

population. Eventually the lynx eat so many hares that the hare population starts to decline. Within 2 years, the decline in hares creates a food scarcity that causes lynx birth rates to go down and death rates to go up, which causes the lynx population to decline. With the decline in lynx predation on the hares and the new increase in plant abundance, the hare population can once again increase, thereby continuing the cycle.

One of the long-term outcomes of predator and prey species interacting is that most species of prey have evolved a variety of antipredator defenses. One of the most common defenses is for prey to hide and

become less active to avoid detection by the predator. Some prey species have also evolved camouflage to help blend into to their environment, such as species of insects that resemble twigs and leaves, as shown in **FIGURE 55.5a**. In other species, prey have evolved morphological defenses, such as the spines of porcupines. One of the most fascinating defenses is that of the bombardier beetle (*Stenaptinus insignis*). The beetle has two glands in its abdomen, with each containing a different chemical. When threatened by a predator, the beetle sprays these two chemicals in the predator's direction, as illustrated in Figure 55.5b. The chemicals react to produce a spray that reaches 100°C, which can

injure or even kill small predators.

FIGURE 55.5 Prey defenses

Predator–prey interactions have led to the evolution of a suite of prey defenses. (a) Some prey have evolved camouflage, such as katydid species that resemble plant leaves. (b) Other prey have evolved chemical defenses, such as the bombardier beetle that can spray a chemical mixture that produces a nearly 100°C spray into the face of its predator.

As discussed in Unit 7, as prey evolve defenses against predators, predators often evolve adaptations to counteract these defenses through the process of coevolution. For example, while most

predators cannot successfully attack porcupines due to the abundance of defensive spines, a large species of weasel known as a fisher (*Pekania pennanti*) has coevolved a unique offense. The porcupine has spines all over its body, except for its face and belly. The fisher attacks the porcupine's face to kill it, and then flips the porcupine over and begins consuming the porcupine by attacking the undefended belly and avoiding the spines.

Parasites and Pathogens

Parasitism is an interaction in which one species lives in or on another

organism, which we call the host. Parasites generally consume the tissues of their host and reduce the host's growth and reproduction, but they rarely kill the host. Some parasites, such as ticks, fleas, lice, and mites, spend a portion of their life attached to their hosts. Parasitic plants such as mistletoes live on other plants. Other parasites, such as tapeworms, fungi, protists, bacteria, and viruses, live inside their hosts.

Parasites that cause diseases in their hosts are known as pathogens, which we first discussed in Unit 7. Some of the best-known pathogens of humans are those that cause COVID-19, swine flu, bird flu, malaria, and the

common cold. Other well known pathogens include a fungus that causes white-nose disease in bats and several species of introduced fungi that cause diseases in crops and wild plants.

When a new pathogen is introduced from another region of the world, it can often have devastating effects on a host species because the host species has not evolved defenses against the pathogen. An excellent example is avian malaria, which is caused by a protist (*Plasmodium relictum*) that was accidentally introduced to the Hawaiian Islands in the early 1900s. The microbe is carried by mosquitoes that feed on

the blood of birds. Avian malaria has caused the decline and extinction of several Hawaiian bird species. Similarly, the American elm tree (*Ulmus americana*) was a common species in North America and was a favorite tree to plant along the streets of towns and cities. In the 1930s a fungus that attacks elm trees was accidentally introduced to North America from Europe. Bark beetles that feed on elm trees carry the fungus from one tree to another. Because the North American elm trees have no evolutionary history with the fungus, they have no evolved defenses. As the fungus spread across North America, it killed nearly 95% of the nation's elm trees.

Herbivory

Herbivory is an interaction in which an animal eats an entire plant or part of a plant. Herbivory benefits the animal, known as an herbivore, but harms the plant by reducing its growth and reproduction. Over time, herbivores can have large impacts on plant communities. For example, when researchers fence off areas of the forest from deer, they observe a substantial amount of plant growth, as shown in **FIGURE 55.6**. Similar to predation, herbivory over long periods of time has favored a variety of anti-herbivore defenses, including spines and distasteful chemicals.

FIGURE 55.6 Effects of deer herbivory

When plots of land were fenced to prevent herbivory by deer, the researchers observed a substantial amount of plant growth inside the fenced area. This confirmed the large impact of herbivores on the plant community.

If a new species of herbivore is introduced from a different region of the world, it can have a devastating impact on plants. For example, the emerald ash borer (*Agrilus planipennis*) is native to Asia, and Asian species of ash trees have evolved resistance to the insect. Around 2002, the beetle was accidentally introduced to Detroit, Michigan, on wooden shipping crates.

The beetle lays its eggs on ash trees and the larvae feed on the cambium and phloem of the trees, ultimately killing an ash tree within 2–3 years. Once again, because ash trees in North America had no evolutionary history with the beetle, the trees have no evolved defenses. By 2020, the beetle had spread north into Quebec and Ontario and south as far as Georgia, killing hundreds of millions of ash trees along the way. Ash trees are economically important as wood for furniture, hockey sticks, and baseball bats, so the widespread death of ash trees is estimated to have resulted in a $1 billion economic loss.

Competition

Competition is an interaction between species that require the same limited resource. For plants, the limited resource could be water, sunlight, soil nutrients, or physical space. For animals, the limited resource could be food, nesting sites, or physical space. Georgii Gause conducted classic lab experiments on competition with two species of *Paramecium* described in Module 54. In these experiments, the two species were fed yeast and bacteria. In a follow-up experiment, Gause grew the two species of *Paramecium* separately and together to determine if one of the species would outcompete the other for the limited food. As you can see in **FIGURE 55.7**, each species

grew to their respective carrying capacities when raised alone, but *P. aurelia* outcompeted *P. caudatum* when the two were raised together. This led Gause to conclude that two species cannot coexist when they compete for a limited resource.

FIGURE 55.7 Competition between *Paramecium* species

When the two species of *Paramecium* were raised separately, shown in parts a and b, both grew well and reached their respective carrying capacities. When the two species were growth together, shown in part c, *P. aurelia* outcompeted *P. caudatum.*

Data from G. Gause. 1934. *The Struggle for Existence.* Williams & Wilkins. Baltimore, MD.

Competition can occur among individuals within a single species, which we refer to as intraspecific competition, and among individuals of different species, which we refer to as interspecific competition. When competition is interspecific, the competitive outcome can be reversed in the presence of a predator or herbivore if it preferentially consumes the best competitor. For example, abandoned farm fields in New England quickly become dominated by a group of tall wildflowers known as goldenrods. This plant is large enough to outcompete smaller species for

sunlight. Occasionally, however, a large population of goldenrod-loving beetles arrive in the field and they eat nearly all of the goldenrod. This allows the other smaller species of wildflowers to gain the resources they need to grow and reproduce.

When two species compete over long periods of time, evolution should favor those individuals with phenotypes that reduce the amount of competition for the limited resource, which we refer to as niche partitioning (also known as resource partitioning). **FIGURE 55.8** visualizes this process. The graph depicts two species of birds that feed on seeds of different sizes, spanning a range from

small to large. If the two bird species initially compete for the intermediate-size seeds, evolution will favor individuals of species 1 that feed on smaller seeds and individuals of species 2 that feed on larger seeds. Natural selection will favor individuals of the two species that reduce the amount of overlap in the sizes of seeds that they eat. Over many generations, the two species experience reduced interspecific competition.

FIGURE 55.8 Resource partitioning

Evolution favors reduced competition between species. (a) Initially, the two bird species show considerable overlap in the seed sizes they eat. (b) Over

evolutionary time, the two species evolve to reduce the amount of interspecific competition.

Mutualisms

As we discussed in Module 12, some species have evolved to live in a close association with another species, which is known as symbiosis. **Mutualisms** are a special type of symbiosis in which both species benefit in regard to their growth or reproduction. One of the best-known mutualisms is the interaction between flowering plants and their pollinators, which can include insects, birds, and bats. In this case,

the plants gain the benefit of achieving breeding through the movement of pollen between flowers, while the pollinators gain a food source from the flower pollen and nectar. Other common mutualisms include lichens and corals, each of which represents two species living in symbiosis with each providing and receiving a benefit. For example, you can often find lichens living on rocks and tree trunks, as shown in **FIGURE 55.9**. They are comprised of an alga or cyanobacterium and one or two species of fungus; the alga carries out photosynthesis and provides sugars to the fungus, while the fungus provides nutrients to the alga. Similarly, corals live in a mutualism with an alga on

coral reefs. The coral is an animal that provides algae with a place to live, while the algae provide valuable sugars to the coral.

FIGURE 55.9 Lichen mutualism

Lichens are a mutualism between an alga or cyanobacterium and one or two species of fungi. The alga carries out photosynthesis and provides sugars to the fungus while the fungus provides nutrients to the alga.

Commensalisms

A **commensalism** is an interaction in which one species receives a benefit while the other species is neither harmed nor helped. For example, gray whales in the ocean often have

barnacles attached to them. The barnacles receive the benefit of being carried to plankton-rich water where they can feed on the plankton. However, the whales do not seem to benefit or be impaired by the attached barnacles. Another common commensalism occurs when seeds with tiny hooks become attached the fur or feathers of animals. The plant benefits by having its seeds dispersed to new areas, but the animals are generally not helped or harmed by the attached seeds.

As we have seen, species living in a community can interact in a number of ways that have negative, positive, and neutral effect on the fitness of the

two participants. TABLE 55.2 presents a summary of these interactions.

Type of interaction	Species 1	Species 2
Predation	+	−
Parasitism	+	−
Herbivory	+	−
Competition	−	−
Mutualism	+	+
Commensalism	+0	+

TABLE 55.2 Interactions between Species and Their Effects

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should know that symbiosis describes a close, long-term biological interaction between members of two different species. Make sure you use the correct type of

symbiosis when describing this relationship.

✓ Concept Check

4. **Describe** why predator and prey populations can cycle over time.

5. **Describe** the difference between parasites and pathogens.

6. **Describe** how predators or herbivores can reverse the outcome of competition.

55.3 Species interactions cause direct and indirect effects in communities

Now that we understand the ways in which pairs of species can interact, we want to consider the full suite of species that live together in communities. In this section, we will examine how a single species can sometimes have a very large effect on the abundance and composition of many other species in the community. We will also consider the

interconnectedness of species and how this allows the effect of interactions between two species to have cascading effects through the entire food web.

Keystone Species

While communities can contain a large number of species, sometimes we find that one particular species, known as a **keystone species**, has a disproportionate impact on the other species even though it may not be very abundant. The term "keystone" is a metaphor that comes from the field of architecture, describing an arch built of stones. In such an arch, the keystone is the center stone that

carries very little weight of the arch yet is critical in keeping the arch from collapsing. In the same way, a keystone species keeps a community from collapsing into a very different collection of species.

One of the best-known keystone species is the beaver (*Castor canadensis*), which lives in forests throughout North America. Beavers construct dams out of branches and mud to convert a flowing stream into a non-flowing pond that floods large areas of the forest, as shown in **FIGURE 55.10**. The water kills many trees that cannot tolerate the flooding. The pond created by the beaver attracts many species with

niches that are well adapted to the new habitat, including ducks that feed on pond invertebrates and woodpeckers that feed on insects living under the bark of the dead trees. Thus, despite being not very abundant, a few beavers can completely alter a habitat and the species that live there. Because beavers completely transform the environment in which they live, they are often called ecosystem engineers.

FIGURE 55.10 A keystone species

Keystone species are those species that have a disproportionate impact on other species even though they may not be very abundant. A common keystone species is the beaver, which builds dams

on streams and creates a large pond. When this happens, the beaver completely changes the community of species that are present, including ducks that feed on pond invertebrates and woodpeckers that feed on insects living on the trees killed by the flooding.

Direct and Indirect Food-Web Effects in Communities

In all the species interactions we have discussed, we have examined how the presence of one species affects the abundance of another species with no intermediate species involved, which

we call direct effects. This includes predators reducing the abundance of their prey and pollinators increasing the abundance of a plant species that they pollinate. However, we know that communities can have a large number of species interacting within complex food webs, so we need to realize that the presence of a species not only has direct effects, but its impact can cascade through a food web and affect many other species. When one species affects the abundance of another species by way of one or more intermediate species, we call it an indirect effect.

We saw an example of an indirect effect earlier in our discussion of the

cycling lynx and hare populations. When there was a growing population of lynx, they killed more hares and this caused an indirect positive effect on the abundance of the plants that hares eat. Similarly, when wolves (*Canis lupus*) hunt elk (*Cervus canadensis*), the number of elk can decline and then the herbivory of the elk on plants declines. As a result, the presence of the wolf has a negative direct effect on the elk, but a positive indirect effect on the plants. When such indirect effects are initiated by the presence of a predator, we call it a **trophic cascade**.

✓ Concept Check

7. **Describe** the role of beavers as

keystone species.

8. **Distinguish** between direct effects and indirect effects of a species on a community.

55.4 Communities experience disturbances that cause changes in species abundance and composition

When we think about the species composition of communities, it is tempting to think that this composition is static. However, the species composition of a community can change dramatically over time as species replace each other in a process known as succession. The process of succession commonly follows a major disturbance.

Succession in Terrestrial Communities

In terrestrial communities, a major disturbance can occur from natural causes such as when volcanoes, fires, or hurricanes destroy most or all the

plants and animals in an area. However, a disturbance can also be caused by human activities, such as clearing a forest or field for agriculture, or covering an old landfill with soil. In most cases, the process of succession happens slowly and can take hundreds of years to fully unfold. As a result, biologists have taken advantage of opportunities to follow disturbed areas over long periods of time.

For example, on the island of Krakatau in Indonesia, a volcano erupted in 1883. The eruption blew away three-quarters of the island and destroyed all life by burying it in lava and ash. Researchers immediately

began visiting the island to monitor when different species of plants began to appear through the process of succession. When they categorized the plants that arrived on the island based on three modes of seed dispersal, an interesting pattern appeared, which you can see in **FIGURE 55.11**. The first plants to arrive were those with sea-dispersed and wind-dispersed seeds. Only after several plants got a foothold on the ash-covered island did some animal species, such as birds and bats, begin to arrive. When the animals arrived, they inadvertently carried animal-dispersed seeds. This pattern of arrival and change over time is an example of succession.

FIGURE 55.11 Succession on Krakatau Island in Indonesia

A volcano on the island that erupted in 1883 blew away three-quarters of the island and covered the remaining land in lava and volcanic ash. Over time, plants began to arrive. The first to arrive were sea-dispersed and wind-dispersed seeds. Later, animals arrived and inadvertently carried with them animal-dispersed seeds.

Data from Whittaker, R. J., et al. 1989. “Plant Recolonization and Vegetation Succession on the Krakatau Islands, Indonesia.” *Ecological Monographs* 59:59–123.

Another way to observe succession is

to study the plants and animals in areas that have been disturbed at different times in the past and then quantify the current composition of species. An excellent example of this happened when Duke University in North Carolina purchased 1900 hectares of what is today known as the Duke Forest. This property consisted of a large number of farm fields that had been abandoned at different points in the past. When ecologists visited these sites after the purchase, they noticed that the recently abandoned fields contained grasses and wildflowers, whereas the fields that had been abandoned for more than 100 years were now covered in forests of oak and hickory

trees. With records of when each farm was abandoned, the researchers could piece together the process of succession as it transitioned from one composition of plants to another, as shown in **FIGURE 55.12**. Because each animal has a specific niche, the researchers found that the composition of animal species also changed over time as the composition of plant species changed.

FIGURE 55.12 Terrestrial succession in abandoned farm fields

By examining the vegetation present in farm fields that had been abandoned at different time points in the past, researchers in North Carolina could determine how the plant community

changed over hundreds of years.

Succession in Aquatic Communities

Succession also occurs in aquatic communities. In streams, for example, we can follow the process of succession after major flooding events in which the rushing water destroys all the plants, animals, and algae in the stream. Only rocks and sand remain. In just a matter of days, different groups of producers start to reappear, beginning with a group of algae known as diatoms and followed by cyanobacteria and green algae. You can see these data in **FIGURE**

55.13a. With the return of the various algal groups, the stream invertebrates also started to return over the next 60 days, as shown in Figure 55.13b. In "**Visual Synthesis 8.3: Succession: Ecology in Microcosm**" you can see how succession proceeds in ponds and on land, as well as the impacts of human activities on succession.

FIGURE 55.13 Stream succession

When the Sycamore Creek in Arizona experienced a major flood, it destroyed all the plants, animals, and algae and left behind bare rocks and sand. (a) Within weeks, different groups of algae began to reappear through the process of succession. (b) Once the algae returned, the number of invertebrate

animals rapidly increased over the next 60 days.

✓ Concept Check

9. **Describe** how the succession of plants would lead to the succession of animals, using abandoned farms in North Carolina as an example.

10. **Describe** how species richness is expected to change in a stream that experiences a major flood event.

Module 55 Summary

REVISIT THE BIG IDEA

PREP FOR THE AP® EXAM

ENERGETICS: Describe the series of community changes that occurred after the Krakatau volcano eruption, paying particular attention to the energy relationships among the populations in the community.

LG 55.1 Community structure includes species diversity and distinct niches.

- Simpson's diversity index is based on knowing both the number of species in a community and the relative proportion of each species, which represents a measure of evenness. Page 779
- A habitat is the physical setting where a species lives. Page 782
- A species' niche is the range of conditions where it can survive, grow, and reproduce. Page 782
- The full suite of abiotic conditions that allow a species to survive, grow, and reproduce is its fundamental niche. Page 782
- The range of abiotic plus biotic

conditions under which a species survives, grows, and reproduces is its realized niche. Page 783

- Some species are categorized as niche generalists because they can live under a wide range of abiotic and biotic conditions whereas other species are considered niche specialists because they only live under a very narrow range of conditions. Page 783

LG 55.2 Community structure also includes a diverse set of species interactions.

- Predation is an interaction that involves one species killing another and consuming it. Page

784

- Predators can have a large impact on the populations of their prey and their effect can cause predator and prey populations to cycle up and down. Page 784
- One of the long-term outcomes of predator and prey species interacting is that most species of prey have evolved a variety of antipredator defenses. Page 785
- Parasitism is an interaction in which one lives in or on another organism, which we call the host. Page 785
- Some parasites cause diseases in their hosts, so we refer to them as pathogens. Page 785
- Herbivory is an interaction in

which an animal eats an entire plant or part of a plant. Page 785

Review Questions

1. Which statement is true about habitats and niches?

A. A habitat is the physical setting where a species lives.
B. A habitat is the range of conditions where a species can grow but not survive.
C. A realized niche is the suite of abiotic conditions that allow a species to survive, grow, and reproduce.
D. A fundamental niche is the range of abiotic plus biotic

conditions under which a species can survive, grow, and reproduce.

2. Why do some species of predators and prey experience population cycles?

A. Predators are able to drive the prey population extinct.
B. When prey increase in abundance predators are able to increase in abundance.
C. Prey run out of food and the entire prey population dies of starvation.
D. When prey decline in abundance the plants they eat also decline in abundance.

3. Which statement is true about competition?

A. Natural selection favors those species that increase their niche overlap.
B. Competition can be intensified by the presence of predators.
C. Natural selection favors individuals that have less resource overlap between two competing species.
D. Competition can occur between different species, but not within a species.

4. Which statement is false about Simpson's diversity index?

A. It takes into account species

richness.

B. A high species richness produces a higher index value.

C. It includes a measure of species evenness.

D. Greater species evenness produces a lower index value.

5. Which statement is true about succession?

A. Succession is the gradual replacement of species over time.

B. Succession only occurs in terrestrial communities.

C. Succession causes a decline in species richness over time.

D. Succession only occurs in aquatic communities.

Module 55 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

1. A group of students make multiple trips to a local park to record the types and numbers of birds living there. Over the course of a semester, students observe 4 cardinals, 13 robins, and 2 blue jays. What are the species richness and Simpson's diversity index for the birds in this park?

A. The species richness is 19 and Simpson's diversity index is 0.377.
B. The species richness is 19 and Simpson's diversity index is 0.477.
C. The species richness is 3 and Simpson's diversity index is 0.377.
D. The species richness is 3 and Simpson's diversity index is 0.477.

2. The rocks of the Pacific Coast of North America are a habitat for a number of marine animal species, including small clam-like animals called mussels. Mussels cling to and live on rocks that are covered with water at high tide

and exposed to the air at low tide. Ecologists studying the rocky Pacific Coast observe that mussels proliferate and completely cover the rocks in a particular stretch of coastline, except where sea stars (starfish) are present. On rocks with sea stars, there are few or no mussels. All the rocks in the region have the same exposure to the ocean; sun; and predatory birds, mammals, and fish. Which of the following best describes the observations that the ecologists made?

A. The entire rocky Pacific Coast is the mussels' fundamental niche, and the rocks where sea stars are present are the

mussels' realized niche.

B. The entire rocky Pacific Coast is the mussels' fundamental niche, and the rocks where sea stars are absent are the mussels' realized niche.

C. The entire rocky Pacific Coast is the mussels' realized niche, and the rocks where the sea stars are present are the mussels' fundamental niche.

D. The entire rocky Pacific Coast is the mussels' realized niche, and the rocks where the sea stars are absent are the mussels' realized niche.

Use the following information to answer questions 3 and 4.

A group of researchers study the interaction of two species of small fish in a controlled laboratory environment. The researchers record the population sizes of the two species when they are grown in separate tanks, and when they are grown together in the same tank. They record the population sizes of the two species over 6 months and graph the data collected as in the following graph.

1. Based on the data in the graph, predict what type of interaction the two species exhibit when grown together.

A. Parasitism
B. Mutualism
C. Commensalism
D. Predation

2. If the two species were competitors and species A was the better competitor, predict what the curve would look like for species B when living with species A.

   A. The curve representing species B living with species A would have a negative slope and would always be lower than the curve representing species B living alone.
   B. The curve representing species B would have a positive slope

but it would always be lower than the curve representing species B living alone.

C. The curve representing species B living with species A would have the same slope as the curve representing species B living alone.

D. The curve representing species B living with species A would have the same slope as it does in the current graph.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required,

show your work.

Ecologists are studying a newly discovered valley. They observe that two species of plant, species 1 and species 2, are always present in the fields of the valley. They want to know what type of interaction, if any, the two plants have with one another. To answer this question, the ecologists find three 1-acre plots in a field that are identical in soil type, rain, temperature, the amount of sunshine, and mineral nutrients. The ecologists completely remove the vegetation in each plot and then, in plot A, they plant only species 1. In plot B, they plant only species 2. In plot C, they plant both species. In each plot, the

plants are placed an equal distance from each other. After the growing season ends, the ecologists measure the biomass of the plants belonging to species 1 and species 2. The results are listed in the following table.

	Plot A mean dry mass per plant (g)	Plot B mean dry mass per plant (g)	Plot C mean dry mass per plant (g)
Species 1	3080.5	2820.7	
Species 2	1579.8	1582.8	

a. **State** the null and alternative hypotheses for the experiment.
b. **Identify** the dependent and independent variables of the experiment.
c. Determine if species 1 and species 2 interact. If the two

species do interact, **identify** the type of interaction. **Justify** your answer.

VISUAL SYNTHESIS 8.3 SUCCESSION ECOLOGY IN MICROCOSM

Ecological succession occurs in both aquatic and terrestrial communities. In newly created ponds, the first organisms to arrive are microorganisms and insects, followed by aquatic birds. In some cases, fish can arrive when nearby water bodies overflow into the pond. As the pond ages, it slowly fills in with dead organic material and eventually becomes a terrestrial habitat. The terrestrial habitat also undergoes

succession. In this example, terrestrial succession moves from grasses to shrubs and then trees. Human activities such as farming and logging speed up or reverse the process of succession.

Module 56

Biodiversity

LEARNING GOALS

- **LG 56.1 Biodiversity exists at several levels and is driven by multiple processes.**
- **LG 56.2 Biodiversity can influence ecosystem organization, productivity, and resilience.**
- **LG 56.3 Biodiversity provides benefits to humans and its distribution varies with latitude.**

In the previous module, we learned

about ecological communities and the many types of interactions that exist among species in a food web. We also learned that we can quantify the diversity of these species in terms of number and evenness by calculating Simpson's diversity index. We also explored the ideas of habitats and niches that species have evolved to fill. We then discussed the various types of species interactions including predation, parasitism, herbivory, competition, and mutualisms. Finally, we explored the importance of keystone species and succession in ecological communities.

In this module, we will explore the

concept of biodiversity in more detail by considering biodiversity at several different levels. We will also review the many causes that drive increases in genetic diversity and species diversity. With this understanding, we will explore global patterns in biodiversity and how these patterns have helped to prioritize the protection of biodiversity. Finally, we will discuss the value that biodiversity has for humans and natural ecosystems.

FOCUS ON THE BIG IDEAS

PREP FOR THE AP® EXAM

SYSTEMS INTERACTIONS: Focus on

the relationship between ecosystem diversity and the ability of an ecosystem to bounce back after an environmental disturbance.

a. Genetic diversity

b. Species diversity

c. Ecosystem diversity

56.1 Biodiversity exists at several levels and is driven by multiple processes

When we consider biological diversity, also known as biodiversity, we can think about it at multiple levels including genetic diversity, species diversity, and ecosystem diversity. You can see these different levels illustrated in **FIGURE 56.1**. Genetic diversity is the variety of genotypes present within a given population or species. As discussed in the previous module, species diversity is the number of species and the evenness of their abundance. Ecosystem diversity refers to the variety of ecosystems in a region, such as a mix of adjacent aquatic and terrestrial ecosystems. In this section, we will discuss the causes of genetic and species diversity.

FIGURE 56.1 Levels of biodiversity

Biodiversity exists at multiple levels. (a) Genetic diversity is the collection of different genotypes present within a given species. (b) Species diversity is the number of different species and the evenness of their relative abundances. (c) Ecosystem diversity is the number of different ecosystems in a given area.

Genetic Diversity

As we have discussed in several previous units, including Unit 5 on heredity, Unit 6 on gene expression, and Unit 7 on evolution, genetic diversity arises from multiple processes. At the level of cells, these

processes include independent assortment, recombination, and mutation. At the level of populations, these processes include genetic drift, population bottlenecks, founder effects, and natural selection. In all these cases, there is an increase or decrease in the amount of genetic variation over time.

As we have also discussed, high genetic diversity allows populations to respond to changing environmental conditions, so at least a portion of the population can survive the environmental change and continue to persist for many generations to come. For example, the blue moon butterfly (*Hypolimnas*

bolina), shown in **FIGURE 56.2**, lives on the South Pacific island of Savaii and more than a century ago the population was parasitized by bacteria. The bacteria kill the male embryos of the butterfly but not the female embryos. As a result, the butterfly population contained 1% males and 99% females. In 2007, however, researchers discovered that the butterfly population rapidly shifted from 1% male to 40% male as a result of a new mutation that is resistant to the parasite. Once the mutation appeared, the mutation favoring male survival spread through 12 generations in a single year, which demonstrated that evolution can occur rapidly once the necessary

genetic diversity is present.

FIGURE 56.2 The blue moon butterfly

When parasitized by bacteria a century ago, the bacteria killed male embryos, resulting in the species being 1% male and 99% female. When a recent mutation provided resistance to the bacteria, the population rapidly evolved to become 40% male.

Another driver of genetic diversity is the process of artificial selection, in which humans purposefully or accidentally favor the survival and reproduction of certain genotypes. As we discussed in Module 41, artificial selection has produced a tremendous amount of genetic variation in domesticated animals and plants

including the diverse breeds of dogs, cattle, sheep, and horses that we see around the world. In many cases, we have breeding records from the past several hundred years, which show how humans have selected for features including size, hair color, meat production, or other heritable features. In plants, humans have also selected for different features. For example, using the wild mustard plant, humans have selected for different stem, leaf, and flower traits as illustrated in **FIGURE 56.3**. This has produced a diversity of genotypes and phenotypes that still make up a single species, including cabbage, cauliflower, kohlrabi, and kale.

FIGURE 56.3 Artificial selection in

crop plants

Starting with the wild mustard plant, humans have selected for different stem, leaf, and flower traits to produce a wide diversity of crops that all belong to the same species.

In contrast to the intentional breeding of different genetic varieties of animals and plants, sometimes artificial selection is accidental, as we first discussed in Module 41. An excellent example of this is the evolution of antibiotic-resistant bacteria. For instance, tuberculosis is a disease caused by a bacterium (*Mycobacterium tuberculosis*) that

infects the lungs and other parts of the body, causing weakness, damaged tissues, and coughing up blood from the lungs. Tuberculosis can be highly lethal, but medical researchers have developed antibiotic medications to kill the bacteria. Although the antibiotic kills nearly all the bacteria, occasionally mutant bacteria have high resistance to the antibiotic, so they survive and proliferate. Over the years, there has been an increase in cases of evolved antibiotic-resistant tuberculosis bacteria and these genotypes require much stronger medications to combat. This underscores the need for us to be aware of unintentional artificial selection that can alter genetic

diversity in ways that benefit the bacteria but harm humans.

Species Diversity

In the previous module, we saw how to quantify species diversity using Simpson's diversity index, which looks at the number of species and the evenness of their relative abundance. We also looked at one reason different places have high or low species diversity: disturbance and ecological succession. These factors produce a change in the composition of species over time, as when a field slowly grows into a forest. A number of other factors also affect species diversity including habitat size,

habitat diversity, and keystone species.

For example, if we examine the number of amphibian and reptile species living on islands of different sizes in the Caribbean, we see that there is a positive relationship between the size of the island and the number of species, as shown in **FIGURE 56.4**. One important reason is that larger islands can sustain larger populations of each species because there are more resources. Larger populations make these species less susceptible to extinction. In addition, larger islands have more distinct habitats, so there are more niches that can accommodate more

species on large islands. Finally, larger islands are easier for species to find and colonize.

FIGURE 56.4 Effects of island size on species richness

When researchers counted the number of amphibians and reptiles on islands in the Caribbean, they discovered a positive relationship such that larger islands contained more species. Note that the figure uses a log scale for both axes.

Data from MacArthur, R. H., and E. O. Wilson. 1967. *The Theory of Island Biogeography.* Princeton, NJ: Princeton University Press.

Another factor that determines

species richness is habitat diversity. We mentioned that larger islands have more distinct habitats, but now we want to focus on the diversity of niches within a given habitat. Consider the situation of birds that live in habitats containing only short plants—such as grasses and wildflowers—versus habitats that contains short plants and shrubs and habitats that contain short plants, shrubs, and trees. As we move across this gradient, there are many more ways for bird species to make a living when there is a greater diversity of foliage heights to live in. In a classic study, researchers examined the diversity of foliage height in the United States and Panama by using an

index of diversity similar to Simpson's diversity index. They discovered that habitats with a higher diversity of foliage heights also contained a higher species richness of birds, as illustrated in **FIGURE 56.5**. Thus, increased habitat diversity helps to drive increases in species richness.

FIGURE 56.5 Effects of habitat diversity on species richness

Researchers examined habitats with a low diversity of foliage height, such as fields with grasses and wildflowers, versus habitats with much greater foliage height diversity, such as a forest containing wildflowers, shrubs, and trees. Habitats with greater foliage height diversity contained more species

of birds. Foliage height diversity and bird diversity were quantified using an index of diversity similar to Simpson's diversity index.

Data from MacArthur, R. H., and J. W. MacArthur. 1961. "On Bird Species Diversity." *Ecology* 42:594–598.

Another important factor in determining species richness is the presence of keystone species, which we introduced in Module 55. As you likely recall, a keystone species is a species that is not very abundant but has a large effect on the species found in a community, such as a beaver that builds a beaver dam. In some cases, the keystone species can have a major

effect on species diversity. For example, along the coast of Washington state, we find a community of species that live in the intertidal range of the shoreline, which is the rocky shoreline that is exposed during low tide but submerged in ocean water during high tide. Here we can find about 20 species, including sea stars (*Pisaster ochraceus*), mussels (*Mytilus californianus*), limpets, barnacles, and several species of attached algae, as shown in **FIGURE 56.6a**. However, other coastal areas are dominated by mussels with hardly any other species present, as you can see in Figure 56.6b.

FIGURE 56.6 Species diversity in the

intertidal zone

When Robert Paine observed intertidal communities off the coast of Washington state, he found that (a) some sites contained a high diversity of species, while (b) other sites were dominated by a single species of mussel.

In a classic experiment, researcher Robert Paine suspected that the predatory sea star might be a keystone species in this community. To test this hypothesis, he removed the predatory sea stars from a portion of the intertidal habitat that contained a high diversity species, including the sea star, and then

observed how species diversity changed over time compared to a control area where sea stars were not removed. You can see the results of his experiment in **FIGURE 56.7**. Removing the predatory sea stars had a large effect within just a couple of years, reducing species diversity from about 18 species down to just 1 species. The one remaining species was the mussel, which turned out to be such an excellent competitor for rock space that it quickly crowded out all the limpets, barnacles, and attached algae. In the control area that still contained sea stars, there was a small increase in species richness over the decade. The reason for this difference is that the sea star

prefers to eat mussels, so when the sea star is present it preferentially consumes the best competitor, thereby allowing all the other species to occupy the habitat.

FIGURE 56.7 Effects of a keystone species on species diversity

For intertidal communities off the coast of Washington state, one can often find a high species diversity. If the predatory sea stars are removed, species diversity sharply declines to just one species while the control area does not decline. The one remaining species is the mussel, which is a superior competitor and crowds all other species that are attached to the rocks. When the sea star is present, it preferentially eats the

mussels, which allows the other species of attached animals and algae to occupy space on the rocks.

Data from Paine, R. T. 1974. “Intertidal Community Structure: Experimental Studies on the Relationship between a Dominant Competitor and Its Principal Predator.” *Oecologia* 15:93–120.

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should be able to analyze the data in graphs like those presented in this section. Make sure you can identify the overall trends. You should be able to identify specific data points on the graph and

compare them to others.

✓ Concept Check

1. **Describe** the difference between genetic diversity and species diversity.

2. **Identify** three processes that can increase the genetic diversity of a species at the level of cells.

3. **Describe** the factors that can affect species diversity in an ecological community.

56.2 Biodiversity can influence ecosystem organization, productivity, and resilience

Biodiversity can have substantial effects on ecosystems. In this section, we will examine how different levels of biodiversity affect the organization

of ecosystem, such as when a keystone species is lost from the system. Higher biodiversity can also increase the productivity of an ecosystem by including species with a greater diversity of niches. Finally, increased biodiversity can increase the resilience of ecosystems that experience natural disturbances.

Biodiversity Effects on Ecosystem Organization

The diversity of species can have substantial effects on the organization of ecosystems. For example, a very species-poor ecosystem may only contain producers. As species

diversity increases, the ecosystem can include primary consumers, secondary consumers, and tertiary consumers. The organization of an ecosystem can also be strongly impacted when a keystone species is removed from an ecosystem. As we have discussed, keystone species have a substantial impact on the organization of food webs, so when a keystone species declines in abundance or becomes extinct in an ecosystem, we expect a large change in the ecosystem because no other species in the ecosystem can serve in that role.

For example, sea otters live along the western coast of North America,

where they eat sea urchins. The sea urchins consume large amounts of algae known as kelp, which can grow several meters tall. These underwater kelp forests provide protective habitat for many species of young fish. When sea otters were hunted to near extinction during the 1700s and 1800s, the sea urchin population dramatically increased since they were no longer being eaten by the otters. As the sea urchins became abundant, they consumed much of the kelp, thereby removing the protective habitat for the many species of small fish, as you can see in **FIGURE 56.8**. In short, the removal of a single keystone species completely changed the organization of the

coastal ecosystem. Today, sea otters are protected from hunting, but new diseases are currently threatening sea otter populations, and these diseases pose the threat of causing another major reorganization of the ecosystem.

FIGURE 56.8 Effects of keystone predators being removed from an ecosystem

Sea otters play a key role in determining the species diversity of coastal ecosystems in western North America. (a) Sea otters are large consumers of sea urchins. (b) When sea otters are present, they keep sea urchin numbers down and the habitat contains an underwater kelp forest. (c) When sea otters became

scarce due to overhunting in the 1700s and 1800s, the sea urchins increased in abundance and consumed most of the kelp. This reduction in kelp removed the refuge habitat that many young fish in these coastal areas depend on.

Biodiversity Effects on Ecosystem Productivity

Species diversity also affects the function of ecosystems because of its role in ecosystem productivity, which is the amount of biomass accumulated by all species of producers in a year. A given

ecosystem can vary widely in how many species of producers are present, from just a few species to hundreds of different species. As a result, we can ask whether having more species allows ecosystems to produce the same amount or a higher amount of total producer biomass compared to having fewer species in a given area.

To answer this question, researchers in Minnesota conducted a large experiment in a field cleared of all the existing plants using herbicide applications and fire and sectioned off hundreds of large plots within the field. They then manipulated the diversity of grassland species that

were allowed to grow in each plot, adding seeds of different species ranging from 0 to 32. After seeding the plots, they spent the summer weeding the plots to remove any additional species that appeared. At the end of the growing season, they collected all the plants in each plot and measured their total biomass. As you can see in **FIGURE 56.9**, as the number of plant species increased, the total biomass of producers dramatically increased and then began to level off.

FIGURE 56.9 Effects of plant diversity on ecosystem productivity

In the grasslands of Minnesota, researchers manipulated the number of

plant species living in each plot, ranging from 0 to 32. At the end of the growing season, they harvested all the plants in each plot and measured the total plant biomass. The graph shows that as species diversity increased, there was a dramatic increase in the total plant biomass of the field plots. Error bars are calculated as ±1 standard error on either side of the mean.

Data from Tilman, D., et al. 1997. “The Influence of Functional Diversity and Composition on Ecosystem Processes.” *Science* 277:1300–1302.

Why does species diversity have such a large impact on the productivity of ecosystems? As the number of species

increases, we increase the diversity of niches that are present. Some species have niches that allow them to photosynthesize when sunlight is abundant while others can photosynthesize when sunlight is scarce, such as plants that live under tall trees that cast a lot of shade. Similarly, some species of producers do most of their growing early in the spring while others grow more during the summer or fall. In addition, some species of producers are good at obtaining and storing nutrients and water from the shallow region of the soil whereas other species obtain and store nutrients and water from deeper soils. Given the diversity of niches among producer species, an

increase in the number of species allows a more complete use of the available sunlight, water, and soil nutrients. This translates into an increase in the productivity of the ecosystem compared to ecosystems with fewer species of producers.

We can see another example of biodiversity affecting ecosystem productivity by considering how soil fungi affect plant growth. For instance, there is a special group of fungi, known as mycorrhizal fungi, that make their living in close connection with the roots of many plants. The fungi are mutualists; they provide soil nutrients to the plants while the plants provide the fungi

with the products of photosynthesis. To determine the importance of fungal diversity in a grassland ecosystem, researchers manipulated the number of fungi species in the soil. At the end of the growing season, they measured the biomass of plant roots and shoots as well as the amount of phosphorus that the plants were able to extract from the soil with the assistance of the fungi. As you can see in **FIGURE 56.10**, as the number of fungal species increased in the soil, the plants grew a larger biomass of roots, grew a larger biomass of shoots, and extracted more phosphorus from the soil. This outcome is the result of different fungi having different niches and

different abilities to help the plants improve their growth. The more species of soil fungi present, the more the plants can grow and the more productive the ecosystem becomes.

FIGURE 56.10 Effects of fungal species richness on ecosystems

In a grassland ecosystem, researchers manipulated the number of mutualistic fungi in the soil. As the number of fungal species increased, there was an increase in (a) total root biomass, (b) total shoot biomass, and (c) the total amount of phosphorus that the plants were able to extract from the soil. Error bars are calculated as ±1 standard error on either side of the mean.

Data from van der Heijden, A. G. A., et al.

1998. “Mycorrhizal Fungal Diversity Determines Plant Biodiversity, Ecosystem Variability, and Productivity.” *Nature* 396:69–72.

Biodiversity Effects on Ecosystem Resistance and Resilience

We can also consider how biodiversity affects the stability of ecosystems in terms of their resistance and resilience. Resistance is the ecosystem’s ability to not be impacted by an environmental disturbance, whereas resilience is the

ecosystem's ability to bounce back from an environmental disturbance. A nice example of how species diversity affects the stability of an ecosystem comes from the large grassland plots in a Minnesota field that we discussed earlier, in which researchers manipulated the diversity of plant species. In plots containing 1, 2, 4, 8, or 16 species of plants, the researchers tracked the abundance of the plants and more than 700 species of insects for 11 years to determine how seasonal and annual variation in environmental disturbances, such as drought, affected the stability of the ecosystem. We can see their data on the stability of herbivore species richness in **FIGURE 56.11a** and the

stability of predator and parasitoid species richness in Figure 56.11b. In both figures, we see that increases in plant species richness caused an increase in the stability of the herbivores that depend on these plants and the predators and parasitoids that depend on the herbivores.

FIGURE 56.11 The effects of plant species richness on the stability of a grassland ecosystem

Researchers manipulated the number of plant species in a grassland in Minnesota. (a) They found that grassland plots containing more plant species caused greater stability in the number of herbivore species over 11

years. (b) They also discovered that grassland plots containing more plant species caused greater stability in the number of predator and parasitoid species. (Stability was quantified as the inverse of the coefficient of variation of species richness, which is the standard deviation divided by the mean.) Error bars are calculated as ±1 standard error on either side of the mean.

Data from Haddad, N. M. 2011. “Plant Diversity and the Stability of Foodwebs.” *Ecology Letters* 14:42–46.

We can also see the effects of biodiversity in human-constructed ecosystems, such as agricultural fields used to grow crops. The traditional

method of raising a crop is to grow a single genotype, which we often refer to as a crop variety. Different varieties of crops such as wheat, corn, and rice are bred to perform well under certain climates around the world. However, planting a single variety also presents a risk if an herbivore or pathogen arrives and is able to attack the crop. If the herbivore or pathogen grows well on one individual plant, the population can spread rapidly and decimate the crop. However, what would happen if the field contained higher genetic diversity due to planting a mixture of varieties?

Researchers in China answered this question by working with rice

farmers to plant mixtures of rice seed varieties. A frequent challenge for rice farmers is a fungal pathogen that attacks the rice and substantially lowers the rice production of a field. To combat the fungus, the farmers have to purchase and apply fungicides. However, when farmers planted a diversity of seed varieties, they found that their fungus problem declined dramatically, resulting in an 89% increase in rice production. The reason for this improvement is that the mixture of rice varieties included genotypes that had both high and low resistance to the fungal pathogen. This mix of genotypes made it more difficult for the fungus to spread from one rice plant to another. With such

an increase in productivity, the farmers no longer needed to apply the fungicides, which saved them time and money. Although selection favors the fungus evolving to attack the resistant rice varieties, the mixture of rice varieties is expected to slow the rate of fungal evolution since fungal infections on different rice strains will evolve different strategies.

56.3 Biodiversity provides benefits to humans and its distribution varies with latitude

Given our discussion of the drivers of biodiversity and the global patterns of its distribution, you might ask why it matters. In this section, we will discuss the values of biodiversity to humans. We will also discuss how biodiversity is distributed around the world and how this distribution, combined with human threats, has led to the identification of biodiversity hotspots that help guide conservation priorities.

Benefits to Humans

The benefits of biodiversity to humans, sometimes referred to as ecosystem services, include both economic values and intrinsic values.

Examples of economic values include the natural products that humans use, including lumber, fur, meat, and crops. Medications are a particularly important product from nature. For example, the anticancer drug Taxol comes from the Pacific yew tree (*Taxus brevifolia*), which produces the chemical in its bark to help fend off attacks by harmful fungi. This drug has generated $1.6 billion in annual sales and saved thousands of lives. This is just one of more than 800 pharmaceuticals that come from nature. Beyond these natural products, biodiversity also provides benefits by helping to control floods; filtering our water to make it cleaner; and taking CO2CO_2 out of the air,

which helps slow down the rate of global warming caused by higher CO2CO_2 concentrations in the atmosphere. Finally, biodiversity also provides recreational activities such as hiking, fishing, and bird watching as well as the critical service of pollinating wild and domesticated plants.

In addition to these many economic benefits, biodiversity also has an intrinsic value to many people. For example, the effort to bring the bald eagle back from the brink of extinction was motivated not by economics, but by a sense of moral obligation since it is the national bird of the United States.

Latitudinal Diversity Patterns

One of the most striking patterns of species diversity is that species richness is highest near the equator and lowest near the poles. For example, if you were to walk through a forest in the eastern United States, you might see 10 to 20 different species of trees. However, if you took a similar walk in a tropical rainforest in the Amazon, you would see 300 to 400 different species of trees. If we look at a map of species richness for vascular plants, shown in **FIGURE 56.12**, you can see this pattern of more species near the equator and fewer species near the poles. You can

also see that the large deserts, such as the Sahara Desert in northern Africa and the many deserts of central Australia, have lower species richness because they receive so little rainfall that there is not a lot of vegetation or habitat diversity to support a larger number of species.

FIGURE 56.12 Species richness patterns in vascular plants

The number of vascular plant species is highest near the equator and lowest near the poles. In addition, species diversity is lower in the large deserts, including northern Africa and central Australia.

Data from Mutke, J., and W. Barthlott. 2008. “Biodiversität und ihre Veränderung im

Rahmen des Globalen Umweltwandels: Biologische Aspekte" (Biodiversity and Its Change in the Context of Global Environmental Change: Biological Aspects). In *Biodiversität* (Biodiversity) (Ethik in den Biowissenschaften–Sachstandsberichte des DRZE, Bd.5) (Series: Ethics in the Life Sciences: DRZE Expert Reports, vol. 5), edited by D. Lanzerath, J. Mutke, W. Barthlott, S. Baumgärtner, C. Becker, and T. M. Spranger, 63. Freiburg i.B: Alber.

A similar pattern of species richness can be found in the distribution of animal species. For instance, if we look at the number of mammal species around the world, as shown in **FIGURE 56.13**, we see that there are more species near the equator and

fewer species near the poles. If we were to look at ocean species, we would see a similar pattern. Understanding these patterns of biodiversity is important because it informs us about where most species have evolved, where most species might be at risk of human impacts, and even where we are most likely to find new pharmaceutical drugs from nature.

FIGURE 56.13 Species richness patterns in mammals

Around the world, the highest species richness for mammals occurs near the equator with fewer species near the poles.

Data from Kaufman, D. M. 1995.

“Diversity of New World Mammals: Universality of the Latitudinal Gradients of Species and Bauplans.” *Journal of Mammalogy* 76:322–334.

Biologists have long wondered why these latitudinal patterns exist. For terrestrial plants and animals, biologists have offered a number of hypotheses. Some hypotheses are related to the fact that the tropical habitats near the equator are more favorable to survival than habitats closer to the poles, which experience cold winters and more variable environmental conditions across the seasons. Other hypotheses emphasize the fact that the tropical locations are

much older and contain species that have evolved and diversified into many new species over tens of millions of years. In contrast, habitats closer to the poles, such as northern North America, have experienced multiple instances of glaciers moving southward and eliminating all species. As the glaciers receded, these newly exposed locations had to be colonized by species from more southern latitudes. Thus, regions closer to the poles have had less time for the evolution of new species.

Biodiversity Hotspots

Knowing these latitudinal patterns in

species diversity, we can identify places that have a lot of species, including areas of the tropics and islands that have evolved endemic species, which are those species that are found nowhere else on the planet. As human activities continue to negatively impact the populations of many species, an important question is how we best conserve this biodiversity to prevent extinctions. A very practical challenge is that there is a limit to how much habitat can be protected, often because there is a limited amount of conservation funding available to purchase and protect all these habitats.

In response to this challenge,

biologists have developed a method of prioritizing conservation efforts by identifying biodiversity hotspots. Biodiversity hotspots are defined as those areas with at least 1500 endemic plant species and experiencing at least 70% vegetation removal as a result of human activities. In short, these are areas with a large number of species that face a large threat of being driven extinct. Based on these criteria, biologists have identified 36 hotspots around the world, as illustrated in **FIGURE 56.14**. Although plant species are used to define these hotspots, areas with a high diversity of plant species typically also have a high diversity of animal species.

FIGURE 56.14 Biodiversity hotspots

Biologists have identified 36 regions of the world that have at least 1500 endemic plant species and more than 70% vegetation removal. These locations also contain a high diversity of animal species.

Review Questions

1. Which statement is not true?

    A. Biodiversity only refers to the number of species.
    B. Biodiversity includes genetic diversity.
    C. Biodiversity includes ecosystem diversity.
    D. Biodiversity includes species diversity.

2. Why does genetic diversity improve resilience in human-created crop ecosystems?

A. Genetically diverse crops attract herbivores.
B. Genetically diverse crops can make it harder for pathogens to spread.
C. Genetically diverse crops attract pathogens.
D. Genetically diverse crops repel predators.

3. Why do larger islands contain more species?

A. Larger islands support smaller populations of each species.
B. Larger islands have species

that are more prone to go extinct.

C. Larger islands have greater habitat diversity.

D. Larger islands are closer to the mainland.

4. What is the pattern of plant and animal richness in relation to latitude?

A. More animal species near the equator, but fewer plant species near the equator

B. Fewer animal species near the equator, but more plant species near the equator

C. Fewer animal species near the equator, and fewer plant species near the equator

D. More animal species near the equator, and more plant species near the equator

5. How can increased biodiversity affect ecosystem processes?

A. Increases in ecosystem stability
B. Reductions in plant growth
C. Declines in the movement of phosphorus from the soil
D. Reductions in primary productivity

Module 56 AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–4.

Use the following information to answer questions 1–3.

Ecologists conducted an experiment in a grassy field. They isolated two $3' \times 3'$ plots in the same field by digging trenches around each plot. At the start of the experiment, both plots had the same environmental conditions and the same number of species present. In plot 1, they removed one plant species, designated plant species X. In plot 2, they removed a different plant

species, designated plant species Y. Both plots were monitored twice a week and, over the 60-month period, plant species X did not regrow in plot 1, and plant species Y did not regrow in plot 2. The ecologists monitored both plots for 60 months to quantify the species richness over time. The data for this experiment are shown in the figure.

1. Which of the removed species was likely a keystone species?

   A. Species X
   B. Species Y
   C. Both species X and species Y
   D. Neither species X nor species Y

2. Which of the following best describes the effect of removing species X?

   A. Removing species X was crucial to maintaining species richness in plot 1.
   B. Removing species X did not affect species richness in plot 1.
   C. Removing species X was crucial to maintaining the genetic diversity of the remaining species in plot 1.
   D. Removing species X was crucial to maintaining the species diversity of plot 2.

3. If both environments contained 100 species at the beginning of

the experiment, what percentage of species was lost from plot 2 over the course of the experiment?

A. 0%
B. 4%
C. 90%
D. 96%

Use the following information to answer question 4.

Ecologists conducted a 23-year experiment in a prairie community to determine which environmental conditions could increase primary production. They plowed plots of ground in the prairie and then seeded each plot with 1, 2, 4, or 16 different

grass species. The ecologists manipulated each plot's amount of nutrients, water, and carbon dioxide, as well as exposure to herbivory, drought, and fire. The ecologists designated one plot as the control plot. The control plot contained 16 species of plants and it did not receive nitrogen-based fertilizer (N), increased water availability, or increased carbon dioxide availability. The control plot was also not exposed to herbivory, drought, or disturbance by fire. The mass of plants that grew in each plot, called biomass, was measured annually for 23 years and compared to the control plot. The results are presented in the figure.

Data from Tilman, D., P. B. Reich, and F.

Isbell. 2012. “Biodiversity Impacts Productivity as Much as Resources, Disturbance, or Herbivory.” *Proceedings of the National Academy of Sciences USA*, 109:10394–10397.

1. Which manipulation caused the greatest increase in plant biomass?

   A. Adding nitrogen fertilizer
   B. Adding water and carbon dioxide together
   C. Increasing the species diversity
   D. Adding a disturbance (drought, herbivory, or fire)

Section 2: Free-Response

Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

Biologists studied the presence of amphibians and reptiles in seven West Indies islands. The results of their studies are presented in the following graph.

Data from MacArthur, R. H., and E. O. Wilson. 1967. *The Theory of Island Biogeography*. Princeton, NJ: Princeton University Press.

a. **Describe** the relationship between the number of amphibian and reptile species with respect to island size. **Justify** your answer.
b. **Explain** why an island the size of Hispaniola has a greater number of amphibian and reptile species than does an island the size of Montserrat.
c. The West Indies island of Trinidad has an area slightly less than 5000 km2$5000\ \mathrm{km}^2$. **Determine** the expected number of amphibian and reptile species on Trinidad. **Justify** your answer.

Module 57

Disruptions to Ecosystems

Unit	51	52	53	54	55	56	57

LEARNING GOALS

- **LG 57.1 Geological and meteorological activity leads to changes in ecosystem structure and dynamics.**
- **LG 57.2 Human impacts accelerate change at local and global levels.**
- **LG 57.3 Human-caused climate change is a global disruption to ecosystems.**
- **LG 57.4 We have solutions to help**

address species declines and disrupted ecosystems.

In the previous module, we examined the multiple levels of biodiversity and the processes that create this biodiversity. We also looked at patterns in biodiversity across latitudes, how it affects the productivity and resilience of ecosystems, and the many benefits that this biodiversity provides to humans. Given the critical importance of biodiversity to ecosystems, we need to understand how natural and human activities can affect biodiversity on local and global scales. When it comes to human activities, the fundamental question is

how we can maintain biodiversity and the benefits it provides as the human population across the globe continues to rapidly grow. In this module, we will begin by examining how geologic factors such as continental drift have altered the distribution of biodiversity on Earth. We will then assess the current state of the world's major groups of plants and animals and consider the underlying causes that are driving current declines in species diversity across major groups of organisms. Finally, we will discuss some current solutions to help reverse these species declines.

FOCUS ON THE BIG IDEAS

SYSTEMS INTERACTIONS: Focus on the connections between human population growth and changes or disruptions to ecosystems.

57.1 Geological and meteorological activity leads to changes in ecosystem structure

and dynamics

A number of geologic and meteorologic events have affected the distribution of ecosystems and the species that comprise these ecosystems. Important geologic events include the historic drift of continents, ice ages, and historic mass extinctions. Substantial meteorologic events include El Niño events that have major impacts on global climates every 5 to 8 years. In this section, we will examine how these events have caused disruptions to ecosystems and species diversity.

Disruptions Caused by Continental Drift

Looking back 250 million years, Earth possessed a single supercontinent known as Pangaea, as illustrated in **FIGURE 57.1**. By around 100 million years ago, Pangaea had broken up into two large continents, known as Laurasia and Gondwana, due to a natural geologic process that we call continental drift. Laurasia subsequently broke up into the modern continents of North America, Europe, and Asia, while Gondwana broke up into South America, Africa, Antarctica, and Australia.

FIGURE 57.1 Disrupted ecosystems due to continental drift

Around 250 million years ago (Mya), modern-day continents were all

connected as one supercontinent known as Pangaea.

Understanding the historic connections among continents helps us understand the modern-day distributions of many species. For example, given that the continents of North America, Europe, and Asia were once all connected, they contain many species that have common ancestors. On all three continents, for instance, we have closely related species of elk, bison, bears, wolves, rabbits, maple trees, and oak trees. In contrast, the unique diversity of marsupial animals in Australia reflects the fact that Australia has

been isolated from other continents for a long time. This long-term isolation allowed natural selection to produce new species that are not naturally found outside of Australia and its surrounding islands in southeast Asia, including kangaroos, koalas, and eucalyptus trees.

While the distributions of species were affected by continental drift, so were the ecosystems. As continents moved to different latitudes, the changing climatic conditions caused major changes in the ecosystems that could be supported. For example, prior to the continents breaking apart, the region now known as Antarctica was located near the

equator and experienced a warm and rainy environment. As a result, the land supported temperate and tropical forests. Today, Antarctica is located near the South Pole with a much colder climate; 2% of Antarctica has a tundra ecosystem containing small, cold-tolerant plants while the remaining 98% is covered in snow and ice.

Disruptions Caused by Ice Ages

The planet has also experienced multiple ice ages in which the temperature of the planet cooled and glaciers advanced to more southern latitudes, including all of Canada and

the northern portion of the United States, from New York City to Chicago. The glaciers eliminated existing plants and animals. As the planet later warmed, the glaciers receded, leaving behind rocks and bare soil that would once again be colonized by species from the south. While some species such as plants with windblown seeds could arrive on bare soil relatively quickly, other species moved northward more slowly. For example, while trees cannot migrate, their seeds can be dispersed slowly northward by animals such as squirrels that collect the seeds and bury them in the ground for winter food. Not all the seeds are eaten, so some germinate

into seedlings and this allows the tree populations to slowly expand northward. Thus, the receding of the glaciers allowed ecological succession to proceed, as discussed in the previous module.

We can determine the historic distribution of trees by identifying when pollen grains of each species appear in lake sediments from the surrounding forests. Lake sediments form in layers, with the youngest layers near the sediment surface, and we can date each layer based on the sediment chemistry. In doing so, biologists have discovered that many tree species took thousands of years to move northward after the most

recent glaciers receded about 12,000 years ago. For example, when we look at two species of pine trees, we see that the extent of their northern distributions, as shown by the red lines in **FIGURE 57.2a**, continued to move northward over a period of 5000 years. In addition, the southern limit of the two pine trees also moved northward. In the case of hickory trees, the northern extent of their distribution experienced a northward expansion over 7000 years, as shown in Figure 57.2b. However, the southern limit of the hickory trees did not shift, which allowed the hickory trees to have a much larger modern-day distribution. As climates changed with advancing and receding glaciers,

the ecosystems found at a given location in North America also changed; the tundra and conifer forest ecosystems that existed just south of the glaciers slowly moved northward as the glaciers receded and these ecosystems were replaced by a temperate deciduous forest.

FIGURE 57.2 Expanding species distributions after glaciers receded

As the final ice age receded about 12,000 years ago, several tree species slowly began a northward expansion of their distributions, which is an example of ecological succession. (a) In the case of two pine tree species, the northern limit of their distribution expanded northward, as shown by the red lines, as

did their southern limit, as shown by the modern-day distribution in green. (b) For hickory trees, their northern limit expanded over thousands of years after the glaciers receded, but the southern limit did not move.

Data from Davis, M. B. 1976. “Pleistocene Biogeography of Temperate Deciduous Forests.” *Geoscience and Man* 13:13–26.

Disruptions Caused by Mass Extinction Events

The composition of our modern ecosystems has also been affected by mass extinctions during Earth’s

history. Mass extinction events are defined as times when at least 75% of the existing species on Earth declined within periods of 2 million years. As you may recall from Unit 7, there have been five mass extinction events in the past. These mass extinctions have several causes in which the environmental conditions of ecosystems around the world have dramatically changed, including ice ages, climate change, volcanic activity, and asteroid collisions. During each event, large numbers of species were unable to adapt to the changing conditions quickly enough. After each event, however, many new species evolved. One interesting result of these mass extinction events

is that while there have been an estimated 4 billion species living on Earth during the past 3.5 billion years, approximately 99% of these species have gone extinct.

When there are major disruptions in species composition, the structure and functioning of ecosystems are also affected. For example, many large herbivores and predators that once existed in North America disappeared around 12,000 years ago, such as wooly mammoths, mastodons, native horses, and saber-toothed cats. Given that humans arrived in North America from Asia 15,000 years ago, the extinctions of these large mammals are thought to

be a combination of human hunting and natural climate changes that caused the advancing glaciers to recede back north.

Researchers who have studied the fossils of animals and plants during this time have discovered that the decline in large herbivores, caused the landscape to be a mix of forests and open areas, as illustrated in **FIGURE 57.3**, similar to the savannas of Africa today. Mastodons functioned as keystone species by consuming shrubs and trees, and trampling the landscape. With the extinction of mastodons, more trees were able to grow and regions from California to Alaska became heavily forested. The

increase in the forested ecosystem subsequently led to the extinction of many species of small mammals. Thus, the extinction of a keystone species can have large effects on both the food web and the structure of the entire ecosystem for thousands of years. This insight is not only of historical interest, but it also serves as a reminder of why we need to prevent the extinction of species today, such as elephants that are experiencing declining populations in the savanna ecosystem of Africa.

FIGURE 57.3 Mastodons

Mastodons are thought to have played an important role in North American ecosystems. When the mastodons were

abundant, they consumed shrubs and trees and trampled the landscape, causing the landscape to be a mix of forests and open areas. When they were driven to extinction by hunting and climate change, more trees and shrubs were able to grow, resulting in forests growing in these areas from California to Alaska.

Disruptions Caused by Meteorological Events

Some meteorological events can have a major impact on ecosystems, as we mentioned earlier in this unit in our discussions of ecological succession and density-independent factors.

Some of these events, such as tornadoes and hurricanes, cause impact in a matter of hours or days, but their effects on the ecosystems can last for decades. For example, forested islands in the Caribbean can be completely destroyed by hurricane winds and heavy rain. Within hours, the once-forested ecosystem is converted to a more open ecosystem consisting of broken-off trees and newly sprouting small plants. However, many of the tree species have adapted to hurricanes by rapidly sprouting new stems from the remaining tree stumps of the hurricane-snapped trees, which allows a more rapid return to a forested ecosystem.

Other meteorological events are less frequent but still cause major disruptions to ecosystems. For example, multiple regions of the world experience dramatic changes in their weather every 3 to 7 years due to a phenomenon known as the El Niño–Southern Oscillation (ENSO). These events are initiated by a substantial change in air pressures in the South Pacific, between Peru and Australia, that causes ocean currents near the equator to no longer flow west; instead, the surface water flows east. This change in direction of wind and ocean surface currents explains the name Southern Oscillation.

While ENSO events are initiated in the

South Pacific, cascading effects are felt around the world because the altered air and ocean currents impact the movement of warm and cold air around the planet as well as the production of low- and high-precipitation areas. For example, during ENSO years, states in the U.S. Midwest can experience severe droughts while other regions can experience increased rainfall and flooding. These effects can last for 1 to 2 years and have major impacts on natural and human-created ecosystems. ENSO events in recent decades have caused large die-offs of fish off the coast of California, corals in Panama, and kangaroo populations in Australia. They have also caused

widespread drought and human starvation in Africa, Australia, and southeast Asia

✓ Concept Check

1. **Describe** how continental drift has caused disruptions to ecosystems.

2. **Describe** how ice ages have altered the structure and function of ecosystems.

3. **Describe** why some species extinctions can have major effects on the structure and functioning of ecosystems.

57.2 Human impacts accelerate change at local and global levels

With our understanding of prehistoric extinctions and disrupted ecosystems, we can now consider these phenomena in more recent times. In this section, we will examine the current rate of extinctions and how a variety of plant and animal groups are experiencing declines. We then want to ask, what are the causes of these declines? We will explore five major causes: habitat loss, invasive species, overharvesting, pollution, and global climate change. While we will discuss each factor separately, many of these factors are acting together to cause the

population declines in many species. We will also see that while some of these factors act locally, others act globally.

A Possible Sixth Mass Extinction

Over the past several centuries, the human population on Earth has grown exponentially, from an estimated 1 billion people in 1800 to more than 7 billion people today. This rapid population growth, as we discussed in Module 48, has resulted in increased human impacts on the environment, including the extinction of many species that have been unable to adapt quickly enough to

increasing levels of human activities. Many biologists have suggested that we might be in the midst of a sixth mass extinction that began with the increase in the human population approximately 10,000 years ago. However, species have also gone extinct in the past, so how does the current rate of extinction compare to the historic rate? How can we test this hypothesis, since a mass extinction event is defined as a 75% loss of species over a period of 2 million years?

One way that biologists have started to assess this hypothesis is to compare the current rate of extinctions against a measure of

historic rates of extinctions. For example, we can examine species for which we have a very good fossil record, such as mammals. When we compare the rate of extinction for mammals during the most recent 500 years with the rate during previous 500-year periods in the past, we find that the current extinction rate is higher. Across all organisms, the United Nations Convention on Biological Diversity estimates that the rate of species extinctions during the past 50 years may be up to 10,000 times higher than the historic rate. Whether this higher rate will result in 75% of our species going extinct over the next 2 million years is not knowable, but it seems clear that we

are currently experiencing a high rate of species extinctions.

The Current Status of Major Plant and Animal Groups

While it is helpful to think about the current versus historic rates of extinctions to assess human impacts on biodiversity, it is also helpful to know how particular groups of plants and animals are faring in regard to whether populations are currently stable or declining. As we discussed in Unit 7, when species face a variety of different human stressors, not all of them can adapt to their changing environments. When this happens,

their populations begin to decline.

To determine how many species are in various states of decline, the International Union for Conservation of Nature (IUCN) has quantified the percentage of each group that is threatened with extinction in the future. As you saw in Figure 48.8, about one-fourth of all animals are threatened, including 40% percent of amphibian species, 25% of mammal species, and 14% of bird species. Of course, there are many other important groups in the world, such as the flowering plants, but the IUCN does not yet have sufficient data on these groups to have reliable assessments of the different

categories.

Habitat Loss

For many species in decline, the primary cause is the loss of habitat, which means these ecosystems are occupying smaller areas than they used to occupy. As we discussed earlier in this unit, each species has a niche that includes the biotic and abiotic conditions required to survive, grow, and reproduce. As we lose habitats due to human activities such as logging, agriculture, home construction, and industries, there is less space for those species that require these habitats, so their populations decline and the structure

of the ecosystem changes.

For example, in the lower 48 states of the United States, there were approximately 89 million hectares (ha) of wetlands in the 1600s, including the Everglades wetlands in Florida shown in **FIGURE 57.4**. Over time, many of these wetlands were drained to increase the land available for agriculture, factories, and homes. Today, the amount of wetland habitat is less than half of what was present in the 1600s. In California, the amount of wetland habitat has declined by 90%. These wetlands are home to species that are not able to live anywhere else, including many species of amphibians, invertebrates,

and aquatic birds. This is just one example of how human activities are causing the loss of ecosystems that are critical for the species that depend on them.

FIGURE 57.4 Wetlands

One of the best-known wetlands in the United States is Everglades National Park in Florida. While the Everglades are federally protected, more than half of the wetlands in the United States have been drained to provide more areas for farming and the construction of factories, businesses, and homes.

Another high-profile example is the loss of forested habitats. For example, in the 1700s and 1800s, most of the forested land in the United States was

cut down to make room for agriculture and buildings and to provide lumber for construction. The good news is that a substantial amount of that cleared land has now grown back into forests as many farms in the eastern United States were abandoned for the more profitable farming opportunities in the Midwest. In fact, much of the modern logging in the United States emphasizes sustainable practices, such as planting trees in logged areas to help speed up ecological succession. However, what are the patterns of deforestation in the rest of the world? If we examine **FIGURE 57.5**, we can see where forested regions of the world are experiencing

increases, decreases, or no change in the amount of forested land. As you can see on the map, many areas in the United States are increasing in tree cover, as indicated by the yellow regions. However, other regions of the world, such as Alaska, Russia, and the tropical regions of South America and central Africa, are experiencing forest loss, as indicated by the blue regions.

FIGURE 57.5 The gain and loss of forested habitats around the world

Forested habitats occur on six continents. As shown by the three colors, some regions of the world are experiencing increases in forested habitat while other regions are

experiencing decreases.

Data from Hansen, M. C., P. V. Potapov, R. Moore, M. Hancher, S. A. Turubanova, A. Tyukavina, D. Thau, S. V. Stehman, S. J. Goetz, T. R. Loveland, A. Kommareddy, A. Egorov, L. Chini, C. O. Justice, and J. R. G. Townshend. 2013. "High-Resolution Global Maps of 21st-Century Forest Cover Change." *Science* 342 (15 November): 850–53. Data available on-line from: http://earthenginepartners.appspot.com/science-2013-global-forest.

Other habitat types are also experiencing declines. For example, according to the most recent Millennium Ecosystem Assessment, the world has lost about 70% of the shrubland habitat that surrounds the

Mediterranean Sea, 50% of all grassland habitats, and 30% of all desert habitats. Coral reefs are another ecosystem that is in decline in many parts of the world. While coral reefs are built by living corals, the reefs also serve as critical habitat for many other species of fish and invertebrates. In the coral reefs of the Caribbean Sea, the amount of living coral declined from 50% in the 1970s to just 8% by 2012.

The reasons for the decline in living coral is a combination of pollutants, increased water temperatures, and the collection of coral by people. From an ecosystem perspective, declines in the more sensitive species

of coral can favor the growth of the more tolerant species of coral, which in turn can alter the species of fish that occupy the reef. These changes in the fish species result in different amounts and types of reef algae that the fish consume. In short, the decline in sensitive species of coral due to human impacts can have dramatic impacts on the structure of entire coral reef ecosystem.

Invasive Species

With the increasing ability of humans to move people and items around the world, we have also moved many species to new locations around the world. Species that currently live in

their historic range are known as native species, whereas species that live outside of their historic range are known as exotic species or alien species. When an exotic species spreads throughout a new area and causes economic or ecological harm, we call it an invasive species. Invasive species are often successful in a new environment because they can exploit unoccupied niches and abundant resources. They usually do not face predators or competition. This allows the invading species to experience rapid population growth to a point where they can alter the structure of ecological communities.

Some exotic species have been

intentionally introduced to new areas, such as honeybees (*Apis melifera*), which were introduced to the American colonies in the 1600s from Europe to provide a source of honey. Similarly, the brown trout (*Salmo trutta*), shown in **FIGURE 57.6**, is native to Europe but has been introduced to many water bodies throughout North America, South America, Australia, Asia, and Africa because it is a favorite game fish for many anglers. Although these species provide economic benefits, they can also disrupt the ecosystems. For example, importing honeybees has led to the decline of many native bee species that compete with honeybees for pollen and nectar from flowers.

Introducing trout to water bodies that have not historically contained trout results in the trout eating large numbers of invertebrates and amphibians that have no defenses against this predatory fish. As a result, large parts of the ecosystem are disrupted as the trout causes major groups of aquatic prey to decline or go extinct, which dramatically alters the flow of energy and matter through the ecosystem.

FIGURE 57.6 Introduced brown trout

The brown trout's historical range is in Europe, and it is a favorite fish for anglers. Given its popularity, the brown trout has been introduced to water bodies throughout North America, South

America, Australia, Asia, and Africa. While the introductions provide benefits to anglers, the trout can have devastating effects on ecosystems by consuming large numbers of prey that have no evolved defenses against the predatory trout.

Unlike honeybees and brown trout, most invasive species arrive in a new area accidentally. For example, the brown rat (*Rattus norvegicus*) is thought to have a historical range in China but by the time of the Industrial Revolution it had spread across Europe. By the mid-1700s, the rat had been accidentally introduced to North America by hitching a ride on ships from Europe. Today, the rat

lives nearly everywhere on the planet where people live. In regions with ground-nesting birds, such as the Hawaiian Islands, the introduced rats have acted as predators on the eggs of these birds. Given that the island birds have no evolutionary history with rats, many were not able to evolve defenses quickly enough and, as a result, several Hawaiian bird species have been driven extinct by the introduced rats. This means that the functions of these birds in the ecosystem are no longer present, so the loss of the birds causes a disruption in the ecosystem.

Invasive species of plants can also have impacts on ecosystems. In the

southeastern United States, for instance, kudzu vine (*Pueraria montana*) was introduced from Asia in the 1930s and promoted as a plant that would help reduce erosion in farm fields and along roadsides. In locations where there is abundant sunlight and no large herbivorous mammals, the vine can dominate the landscape and grow over the tops of trees, as you can see in **FIGURE 57.7**. When this happens, the vines can shade the trees to a point that the trees die and the ecosystem is dominated by the vine. In 2009, however, the kudzu bug (*Megacopta cribraria*) was accidentally introduced from Asia and it favors kudzu. When the kudzu bug finds large areas of

kudzu, it can decimate the plant, so an invasive plant is currently being consumed by an invasive insect that evolved to eat kudzu in Asia.

FIGURE 57.7 The invasive kudzu vine

Widely planted in the 1930s to control erosion on farms and along roadsides, the vine has spread widely and can grow over the tops of buildings and trees.

When pathogens arrive in a new region of the world, they can have large impacts because the hosts that they infect have no evolved defenses. For example, in the 1930s a pathogenic fungus that infects elm trees was introduced to North America from Asia. Given that the fungal infections caused a disease

that was first described by researchers in Holland, it became known as Dutch elm disease. While species of elm trees in Asia had evolved defenses against the fungus, North American elm tree species had no evolutionary history with the fungus, so nearly 95% of them died from Dutch elm disease. Today, young elm trees continue to sprout, but most are killed within their first decade of life. The small number of trees that have survived appear to have more resistant genotypes, so there is hope that the elm trees will continue to evolve higher resistance over time and be able to coexist with the introduced fungus.

Overharvesting

The harvesting of plants and animals by humans for food, fur, and other uses has gone on for millennia, but there is a limit to how many individuals of a species can be harvested before it declines toward extinction. This is particularly challenging as we try to feed a rapidly growing human population. For example, off the coast of Newfoundland, on the eastern side of Canada, there is a large population of Atlantic cod that has been fished for centuries and supported the local economy. Over the decades, fishing boats have experienced numerous technological improvements for more

efficient fishing, including long fishing lines with thousands of fishing hooks and gigantic nets that can surround a 2-km area of fish. With these increases in efficiency, the number of cod caught by commercial fishing boats increased exponentially in the 1960s and 1970s.

However, such a large catch could not be compensated by cod reproduction, so by the 1990s the cod population collapsed to very low numbers, as you can see in **FIGURE 57.8**. In 1992, cod fishing had to be stopped to allow the cod population to rebound. However, this rebound has been slow and a return to sustainable cod fishing off the coast of Newfoundland is not

expected to be possible until perhaps 2030. The large decline in cod has meant that the cod's predatory impacts are no longer present, so their prey are beginning to increase. For example, the abundance of Jonah crabs (*Cancer borealis*), a prey of the cod, has increased fourfold; the now abundant crabs can decimate the abundance of sea urchins. As a result, the overharvesting of the cod can have a large impact on the structure of ocean ecosystems.

FIGURE 57.8 The overharvesting of cod

As technologies improved the ability of commercial fishing boats to catch cod in the 1960s and 1970s, the number of cod

caught off the coast of Newfoundland, Canada, dramatically increased until the population became overharvested. At that point, there was a sharp decline in the cod population and the fishery had to be shut down.

Data from Millennium Ecosystem Assessment. W. Reid, H. Mooney, A. Cropper et. al., 2005: Ecosystems and Human Well-being: Synthesis. Island Press, Washington D.C.

The story of the Atlantic cod near Newfoundland has been repeated all around the world. For instance, rhino populations in Africa have been illegally killed for their horns, which are sold for their reputed medicinal

properties. There are species of rare trees, such as big-leaf mahogany, that are sold for their beautiful lumber, and endangered species of orchids that are dug up in their natural habitats and sold to collectors. The illegal trade in plants and animals is currently valued at $5 billion to $20 billion annually, and this has led to major issues of overharvesting.

Pollution

Pollution has also contributed to the decline of biodiversity in ecosystems. Pollution can appear in a wide variety of forms, including oil spills, pesticides, heavy metals, and even endocrine disruptors, which inhibit

proper reproduction in animals. A high-profile pollution event occurred in the Gulf of Mexico when an oil platform known as the Deepwater Horizon suffered an explosion in 2010 that released a massive amount of oil into the ocean water for months. As the oil continued to pour out of the pipe, it soon became the largest oil spill in U.S. history, totaling 507 million liters of oil.

To break up the oil spill into tiny droplets that could be degraded by bacteria, emergency workers sprayed a chemical onto the oil. However, the chemical is also toxic to many species of aquatic organisms. As the animals were exposed to the oil and the

chemical by way of consumption and inhalation, it caused organ damage and reproductive failure. According to a National Oceanic and Atmospheric Association report in 2017, thousands of species were exposed to the oil spill. For example, Kemp's Ridley sea turtles (*Lepidochelys kempii*) in the area were exposed to the oil spill, as shown in **FIGURE 57.9**, and 20% of them died. In addition, the bottlenose dolphin (*Tursiops truncatus*) population declined by 50% over the next few years. Multiple species of birds were also killed, including large numbers of pelicans and seagulls.

FIGURE 57.9 Pollution effects on biodiversity

During the oil spill from the Deepwater Horizon platform in the Gulf of Mexico, thousands of species were exposed to the oil, including this juvenile Kemp's Ridley sea turtle.

When it comes to pollution, biologists have observed the evolution of increased tolerance to pollutants over several generations, but only in a limited number of cases. For example, repeated applications of insecticides to kill mosquitoes has resulted in artificial selection for the rare mutants that have a genetic resistance to the insecticide, thereby causing the evolution of insecticide-resistant mosquito populations.

✓ Concept Check

4. **Describe** how biologists can assess whether the current rate of extinctions is higher now than in the past.

5. **Identify** which group of animals has the highest percentage of threatened species.

6. **Identify** the biggest threat to species diversity in ecosystems today.

7. **Distinguish** why birds on islands are commonly susceptible to exotic species that are predators.

57.3 Human-caused climate change is a global disruption to ecosystems

When considering human impacts on disrupted ecosystems, we also have to consider the impacts of global climate change, which is the change in the average weather around the planet

over years or decades. An important driver of changing climates is global warming, which is the increase in the temperature of the air, land, and water over years or decades. Over millions of years, the planet has experienced many periods of warming and cooling, as we mentioned in the case of the ice ages that caused glaciers to advance and recede. Of current concern is the role that human activities are having on the temperature of Earth. To understand how global climate change can affect ecosystems, we first need to understand the underlying causes of global warming.

The Greenhouse

Effect

Our planet is surrounded by an atmosphere that contains gases, and 99% of those gases are nitrogen (N 2) (N_2) and oxygen (O 2) (O_2). While abundant, these two gases do nothing to make the planet warmer. The planet is made warmer by a few scarce gases that we refer to as greenhouse gases, which include water vapor (H 2 O) (H_2O), carbon dioxide (CO 2) (CO_2), methane (CH 4) (CH_4), and nitrous oxide (N 2 O) (N_2O). These gases have a unique property; they can absorb and release infrared radiation. When sunlight strikes Earth with visible light and ultraviolet radiation,

that energy gets converted into infrared radiation at the planet's surface. This infrared radiation gets emitted back toward the atmosphere, where the greenhouse gases absorb the infrared radiation and then reemit it in all directions. Some of this energy goes back to the planet and some goes out into space. The portion of infrared radiation that goes back toward Earth is what makes the planet warmer. You can see these processes illustrated in **FIGURE 57.10**.

FIGURE 57.10 The greenhouse effect

Solar radiation from the sun passes through the atmosphere and strikes the planet's surface. The solar radiation is

converted into infrared radiation, which we can think of as heat. A portion of the heat is emitted from the surface of the planet back toward the atmosphere. In the atmosphere, greenhouse gases absorb the heat and then reemit it in all directions. Some of this heat is reemitted back toward Earth, which increases the planet's temperature, and some is lost to space.

It is important to note that greenhouse gases were in the atmosphere long before humans appeared on the planet. Indeed, the natural concentration of greenhouse gases makes the planet about 33°C warmer than it would be otherwise,

making life as we know it possible. Thus, these scarce gases have a very large effect on the temperature of our planet. We call this process the greenhouse effect because it resembles a gardener's greenhouse, which lets light in through the glass windows and then traps the heat inside. The greenhouse effect operates a bit differently in that the heat is not trapped, but rather the infrared radiation from the Earth's surface is absorbed in the atmosphere and then reemitted in all directions, including back to Earth's surface.

Human Impacts on the Greenhouse

Effect

With this knowledge of how the natural greenhouse effect works, we can now examine how humans are altering this process. Humans are increasing the greenhouse effect by increasing the concentrations of carbon dioxide, methane, nitrous oxide, and other chemicals in the atmosphere. The causes of these increasing greenhouse gases include the burning of fossil fuels, raising domesticated animals, deforestation, decomposing landfills, and the production of industrial chemicals.

Beginning in 1958, Dr. Ralph Keeling began measuring the concentration

of CO 2 CO_2 in the atmosphere over several years on top of a mountain in Hawaii. You can see these data in **FIGURE 57.11**. The first thing that he noticed was that CO 2 CO_2 concentrations exhibited seasonal cycles, which are caused by plants and algae taking up CO 2 CO_2 during the spring and summer for photosynthesis. The second thing he noticed was that the amount of CO 2 CO_2 was increasing each year. More than 60 years later, we see that the amount of CO 2 CO_2 in the atmosphere has steadily increased. The amount of CO 2 CO_2 in the atmosphere has increased by 30% since 1958. When we increase the concentration of these greenhouse

gases, the atmosphere can absorb and reradiate more infrared radiation back to Earth, so Earth steadily warms.

FIGURE 57.11 The Keeling curve of increasing CO 2 CO_2 in the atmosphere

Based on measurements of CO 2 CO_2 concentrations made on a mountaintop in Hawaii, we can see seasonal fluctuations in CO 2 CO_2. Over the past 60 years, we can also see that there is a steadily increasing trend of CO 2 CO_2 concentrations over time.

Data from Dr. Pieter Tans, NOAA/ESRL (www.esrl.noaa.gov/gmd/ccgg/trends/) and Dr. Ralph Keeling, Scripps Institution of Oceanography (scrippsco2.ucsd.edu/).

Based on our knowledge of how greenhouse gases absorb and reradiate infrared energy and based on data showing that greenhouse gas concentrations are increasing, we can hypothesize that the planet should be getting warmer. However, do temperature data support this hypothesis? Our direct measurements of temperature go back to the 1800s and these measurements tell us that the mean temperature of the planet has increased by nearly 1°C over the past 140 years. While this number seems small, it is important to know that some regions of the world have cooled a bit whereas others have

warmed a great deal, such as increases of 4°C (7°F) in Alaska, northern Canada, and northern Europe. In **FIGURE 57.12**, we can see temperature changes in just the past 40 years. While some regions around Antarctica have cooled by 1°C, regions on the northern latitudes of North America and Europe have increased by 3°C.

FIGURE 57.12 Global warming around the world

While the mean temperature around the world has increased by about 1°C since the late 1800s, temperature changes vary among different regions. From 1979 to 2019, some areas near Antarctica became 1°C cooler while northern

latitudes became up to 3°C warmer.

Data from https://climate.nasa.gov/blog/3017/making-sense-of-climate-sensitivity/

Impacts of Global Warming on Species and Ecosystems

Given that changes in regional temperatures are relatively small, do they have any effect on biodiversity? The key to understanding the effects is appreciating that small temperature differences can affect important biological processes, such as when flowering plants make their

flowers, when birds migrate, when animals breed, and whether species can survive under the warmer temperatures. For example, in the Gulf of Alaska the ocean temperatures rose 2°C to 3°C beginning in 2014 due to an ENSO event. This increase in temperature was enough to cause poor survival in young cod, which led to a ban on cod fishing in 2019. The warmer ocean temperatures also caused many other species of fish to move deeper into cooler waters, which led to the deaths of nearly 1 million sea birds that depend on these fish for their diet. While this small increase in ocean temperature was caused by an ENSO event, it provides a clear example of

how a small increase in water temperatures can have a wide range of direct and indirect effects on species and the structure of ecosystems. In "Practicing Science: How do changing CO 2 CO_2 levels affect coral reefs?" we discuss experiments that examine how increases in CO 2 CO_2 concentrations can impact coral reef ecosystems.

Practicing Science 57.1

How do changing CO 2 CO_2 levels affect coral reefs?

PREP FOR THE AP® EXAM

Background We have seen that rising CO 2 CO_2 concentrations have

contributed to global warming. However, they can also affect the pH of the oceans, which can have additional effects on biodiversity. For example, coral reefs are built by animals, known as corals, that live in a mutualistic relationship with algae. The algae receive a home and nutrients from the coral while the coral receives sugars produced by the algae. Together, the coral and algae build a rocky skeleton that accumulates over thousands of years and becomes a coral reef. A great diversity of other animals and algae depend on coral reefs for habitat, such as the Great Barrier Reef off the coast of Australia, which is home to more than 1500 species of fish and 4000 species of clams and snails.

It turns out that elevated concentrations

of CO_2 in the air diffuse into the ocean water, which increases the amount of CO_2 in the oceans. In the oceans, much of this CO_2 combines with water and is rapidly converted into carbonic acid (H_2CO_3), which then loses a hydrogen ion (H^+). All these free hydrogen ions cause the pH of the water to go down by about 0.1 pH unit, which is a process called ocean acidification. This may not sound like a large change, but you may recall that pH is measured on a log scale, so this 0.1 decline in pH represents a 30% increase in hydrogen ions in the water. A lower pH might make it harder for the coral and algae to access calcium from the water to grow their calcium carbonate skeleton, which is the backbone of the

coral reef.

Hypothesis Increasing ocean pH will lead to increased construction of coral reef skeletons while decreasing ocean pH will lead to decreased construction of coral reef skeletons.

Experiment 1 In 2014, American biologist Rebecca Albright and her colleagues identified a lagoon within the Great Barrier Reef where coral reefs were isolated from regional currents. In their first experiment, they set up an apparatus that emitted sodium hydroxide (NaOH) for 3 weeks into a current that flowed in one direction over adjacent reefs. NaOH is a base, so it increased the pH of water flowing over the reef to values that resembled the pH of seawater before the Industrial

Revolution. This increase in pH should make it easier to obtain the calcium needed to build the calcium carbonate skeleton. Albright and her colleagues measured the rates of reef building—known as calcification—when NaOH was added to one area and in a control area where NaOH was not added.

Experiment 2 In a second experiment, the researchers added CO_2 to waters flowing over one reef area, in an effort to simulate the projected pH of late-twenty-first-century seawater. Again, they measured rates of reef calcification and compared those to a control area in which no additional CO_2 was added to the water.

Results In part a of the figure below, you

can see the results of the first experiment in which researchers examined a control area of the reef versus a second area in which they added NaOH to the water to increase pH. Increasing the pH caused an increase in the percent calcification, which is a measure of coral reef growth. Adding NaOH increased the pH to pre–Industrial Revolution levels and calcification increased by 7%. No change in calcification was observed in the control area, as you can see in the figure.

In part b of the figure, you can see the results of the second experiment in which researchers examined a control area of the reef versus a second area in which they added $CO\ 2$ CO_2 to the water to decrease pH. Decreasing the pH reduced calcification by 34%. Again, no

change was observed in the control area, as you can see in part b. Error bars are calculated as ± 1 ± 1 standard deviation on either side of the mean.

Conclusion Corals and other reef-building organisms in the Great Barrier Reef are sensitive to ocean acidification, showing an increased ability to form calcium carbonate skeletons under pH conditions resembling pre–Industrial Revolution ocean pH conditions and a decreased ability under late-twenty-first-century ocean pH conditions.

Follow-up Work Reef corals show a consistent vulnerability to pH decline, although some populations appear to be more resistant than others. Resistant corals might provide a means to sustain

reefs in the future, but their ecology will differ from those we see today.

AP® PRACTICE QUESTION

a. **Identify** the following:

1. The question being investigated by the experimenters
2. The null hypotheses they tested
3. The alternative hypotheses they tested
4. The experimental groups
5. The control group
6. The independent variable

7. The dependent variable

b. A statistical test was performed comparing the experimental data with the control data, producing a *P*-value less than 0.05. Explain what this value says about the results.

c. **Explain** the results of the experiments by **identifying** the researchers' claim and **justifying** the claim with the evidence and the reasoning researchers used (CER).

AP® EXAM TIP

PREP FOR THE AP® EXAM

You should understand the causes and effects of global warming, including how it may affect temperatures in various parts of Earth and its role in ocean

acidification.

✓ Concept Check

8. **Describe** the reason that the most abundant gases in the atmosphere do not contribute to global warming.

9. **Describe** how global warming has both a natural and human-caused component.

10. **Describe** how a small decline in pH can cause a decline in the growth of coral reefs.

57.4 We have solutions to help address species declines and disrupted ecosystems

From the previous section, it would be understandable if a person felt overwhelmed by the number of threats to biodiversity caused by human activities. However, there is great reason for hope as we look to

the future. For example, as we learn about the full range of pollution effects, we learn how to limit these pollutants through new regulations or more limited applications that reduce their harmful effects on ecosystems. In this section, we will discuss the great strides we are making toward additional solutions including habitat protection, species reintroductions, reduced harvesting, and reversing global climate change.

Habitat Protection

As we noted in our discussion of biodiversity hotspots in the previous module, there is a current effort to protect habitats that are home to a

large number of endemic species that face threats of extinction. For example, there has been a rapidly growing trend of protecting terrestrial habitats since the 1960s that is now starting to plateau, as shown in **FIGURE 57.13a**. Historically, there has been less emphasis on protecting marine habitats, but the situation began to improve by the 1980s and has dramatically increased since the 2000s, as you can see in Figure 57.13b. These large areas of protected habitats will help many species to avoid extinction.

FIGURE 57.13 Protecting habitats

Throughout the world, there has been a

growing percentage of protected habitats over time. (a) The protection of terrestrial habitats began to increase rapidly in the 1960s and is currently at a plateau. (b) The protection of marine habitats began much later, but is currently increasing rapidly. Note that the two *y*-axes have different scales.

Data from Secretariat of the Convention on Biological Diversity, Global Biodiversity Outlook 4. 2014. https://www.cbd.Int/gbo/gbo4/publication/gbo4-en-hr.pdf, https://www.cbd.int/gbo2/; https://livereport.protectedplanet.net/chapter-2

Controlling Invasive Species and

Reintroducing Native Species

It can be exceedingly difficult to rid an area of an invasive species once the population has spread widely. Given that many invasive species have no substantial predators, parasites, or competitors, there are often few natural controls on their populations. In some cases, invasive species can be harvested to reduce their abundance, such as invasive species of aquatic plants that can be harvested by hand or with machines that cut the aquatic plants like a giant lawnmower. In a few cases, researchers have gone to the region of the world where an invasive species originated to find an

enemy that can control the invasive species, such as a predator, parasite, or herbivore. We saw an example of this with the kudzu vine. When the kudzu bug was introduced to the United States decades after the kudzu vine was introduced, the bug rapidly increased in abundance and began controlling the kudzu vine's population by eating the invasive plants.

In some cases, we have been able to reintroduce native species into their native habitat, thereby bringing them back from the brink of extinction. For example, the California condor (*Gymnogyps californianus*), shown in **FIGURE 57.14**, is a large vulture that

feeds on dead animals. For several decades, its numbers had been declining from a multitude of causes, including illegal shooting, feeding on dead animals that had been killed by bullets and still contained fragments of the lead bullets, and feeding on dead animals that died from eating poisons. By the 1980s, only 22 condors remained. All 22 birds were captured from the wild and held in captivity to produce offspring. At the same time, steps were taken to reduce the threats in the wild so that individuals that were reintroduced to the wild would have a better probability of surviving. This effort was a tremendous success; today there are more than 500 California condors alive in captivity

and in the wild, ranging from California to New Mexico. Similar efforts have been successful with other charismatic species, including black-footed ferrets (*Mustela nigripes*) and gray wolves (*Canis lupus*).

FIGURE 57.14 The California condor

The condor is a species of vulture that feeds on dead animals. During much of the twentieth century, condor numbers declined as the result of illegal shooting and inadvertent poisoning. In the 1980s, only 22 individuals remained in the wild.

Reduced Harvesting

Reduced harvesting is another way to bring species back from the brink of extinction. One way to do this is to

regulate the harvest of plants and animals, particularly those that are commercially harvested, as we saw in the case of Atlantic cod off the coast of Newfoundland. A great example of the power of regulating the harvest of animals is the northern elephant seal (*Mirounga angustirostris*). By the late 1800s, the elephant seal had been hunted so much by humans that biologists thought it was extinct. However, in the 1890s a few small populations were found that numbered approximately 100 individuals. Soon afterward, the U.S. and Mexican governments protected the elephant seal from any further hunting to allow the population to rebound. Over the subsequent

century, the population rebounded to an astounding 150,000 individuals that currently live all along the coasts of California and Mexico.

A similar story occurred with the American alligator (*Alligator mississippiensis*), which was hunted to near extinction in the United States by the 1950s. Once the U.S. government declared the alligator to be endangered in 1967 and stopped all hunting, the alligator rapidly rebounded. By 1987, the alligator was abundant enough to remove it from the endangered species list. Today, there are millions of alligators living in the southeastern United States. The populations are once again hunted,

but the number of harvested alligators is now regulated to prevent the species from ever being overharvested again.

Reducing Global Climate Change

The key to reducing global warming and the associated global climate change lies in reducing the concentration of greenhouse gases in the atmosphere. As we have discussed, greenhouse gases have multiple natural and human sources, which means there are multiple solutions that can help. For example, using less fossil fuel results in less CO2CO_2 being released into the

atmosphere. Individuals can help by driving less, taking public transportation more often, and using energy-efficient appliances and lights. Many companies are moving to renewable energy using solar panels and wind turbines to also reduce their burning of fossil fuels. In addition, companies are increasingly phasing out the use of human-made chemicals that act as very powerful greenhouse gases. Collectively, these efforts will help slow the current rate of global warming, although the efforts will likely take several decades.

✓ Concept Check

11. **Describe** the trends in global

habitat protection over the past several decades.

12. **Describe** how the condor reintroduction program required the mitigation of multiple human impacts.

13. **Describe** how the U.S. government's actions allowed American alligator populations to rebound and remain abundant for the past several decades.

Module 57 Summary

REVISIT THE BIG IDEAS

PREP FOR THE AP® EXAM

SYSTEMS INTERACTIONS: Using one

example from the module, **explain** how continued growth of the human population plays a role in reduced species richness and a decrease in biodiversity.

LG 57.1 Geological and meteorological activity leads to changes in ecosystem structure and dynamics.

- Over millions of years, the diversity of species on Earth has been impacted by natural geologic forces, including continental drift. Page 812
- The planet has also experienced multiple ice ages in which the temperature of the planet cooled and glaciers advanced to more

southern latitudes, including all of Canada and the northern portion of the United States. Page 813

- We can determine the historic distribution of trees by identifying when each species' pollen grains appear in lake sediments from the surrounding forests. Page 813
- The composition of our modern ecosystems has also been affected by mass extinctions during Earth's history. Page 813
- When there are major disruptions in the species present in an ecosystem, the structure and functioning of ecosystems can be affected. Page 814

- Some meteorological events, such as tornadoes and hurricanes, can have a major impact on ecosystems. Page 815
- Other meteorological events, such as ENSO events, are less frequent but still cause major disruptions to ecosystems. Page 815

LG 57.2 Human impacts accelerate change at local and global levels.

- Rapid human population growth has resulted in increased human impacts on the environment, including the extinction of many species. Page 815
- Many biologists have suggested that we might be in the midst of a sixth mass extinction. Page 816

- For many species in decline, the primary cause is the loss of habitat. Page 816
- Many areas in the United States are increasing in tree cover, but other regions of the world are experiencing forest loss. Page 817
- The world has lost about 70% of the shrubland habitat that surrounds the Mediterranean Sea, 50% of all grassland habitats, and 30% of all desert habitats. Page 817
- With the increasing ability of humans to move people and items around the world, we have also moved many species to new locations around the world. Page 817

- When an exotic species spreads across a new area and causes economic or ecological harm, we call it an invasive species. Page 817
- Most invasive species arrive in a new area accidentally. Page 818
- When pathogens arrive in a new region of the world, they can have large impacts because the hosts that they infect have no evolved defenses. Page 818
- The harvesting of plants and animals by humans for food, fur, and other uses has gone on for millennia, but there is a limit to how many individuals of a species can be harvested before the species declines toward

extinction. Page 819

- Overharvesting of a species can have a large impact on the structure of an ecosystem. Page 819
- Pollution has also contributed to the decline of species and disrupted ecosystems. Page 819

LG 57.3 Human-caused climate change is a global disruption to ecosystems.

- Global climate change is the change in the average weather around the planet over years or decades. Page 820
- An important driver of changing climates is global warming. Page 820

- The planet is made warmer by a few scarce gases that we refer to as greenhouse gases, which include water vapor, carbon dioxide, methane, and nitrous oxide. Page 821
- Humans are increasing the greenhouse effect by increasing the concentrations of carbon dioxide, methane, nitrous oxide, and other chemicals in the atmosphere. Page 821
- Some regions of the world have cooled a bit whereas others have warmed a great deal, such as increases of 4°C (7°F) in Alaska, northern Canada, and northern Europe. Page 822
- Small temperature differences

can affect important biological processes, such as when flowering plants make their flowers, when birds migrate, when animals breed, and whether species can survive under the warmer temperatures. Page 822

- In addition to rising CO 2 CO_2 concentrations causing global warming, they also can affect the pH of our oceans, which has additional effects on ecosystems. Page 822

LG 57.4 We have solutions to help address species declines and disrupted ecosystems.

- There has been a rapidly growing

trend of protecting terrestrial habitats since the 1960s that is now starting to plateau. Page 824

- There has been less emphasis on protecting marine habitats, but the situation started to improve by the 1980s and has dramatically increased in the 2000s. Page 824
- It can be exceedingly difficult to rid an area of an invasive species once the population has spread widely. Page 824
- In some cases we have been able to reintroduce native species into their native habitat. Page 825
- Reduced harvesting is another way to bring back species from the brink of extinction. Page 825
- The key to reducing global

warming and the associated global climate change lies in reducing the concentration of greenhouse gases in the atmosphere. Page 825

Review Questions

1. Which is not true about ice age effects on species diversity?

A. Species of pine trees colonized areas where glaciers receded within a few decades.
B. Advancing glaciers destroyed all plant and animal diversity in their paths.
C. Receding glaciers revealed bare soil for ecological succession to begin.
D. Advancing glaciers caused

many species to experience altered distributions.

2. Why do many biologists think that we may be experiencing a sixth mass extinction?

A. The current rate of extinction is greater than other mass extinction events.
B. We have experienced 75% of extinct species during the past 2 million years.
C. The current rate of extinction is higher than rates in previous 500-year periods.
D. There have been more extinctions during the past century than at any time in Earth's history.

3. Which statement is not true about causes of decline in biodiversity?

A. Unregulated commercial harvest has led to declines in many populations.
B. Habitat loss is a minor cause.
C. Exotic species are often accidentally introduced.
D. Pollutants can kill some species, leading to population declines.

4. Which is not a greenhouse gas that contributes to global warming?

A. Water vapor
B. Carbon dioxide
C. Methane
D. Nitrogen gas

5. Which statement is true about solutions for reversing the decline in species diversity?

A. Species reintroductions work even if the human threats are not mitigated.
B. We are experiencing a decline in the amount of habitat being protected around the world.
C. Reduced harvesting does not substantially help populations rebound.
D. It is easy to control populations of exotic species.

Module 57 AP® Practice Questions

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–5.

Use the following information to answer questions 1–3.

The figure depicts the growth of the human population over the past 200 years and the number of species that went extinct over the same period.

Source: Scott, J. M. 2008. *Threats to Biological Diversity: Global, Continental, Local.* U.S. Geological Survey, Idaho Cooperative Fish and Wildlife, Research

Unit, University of Idaho.

1. Which of the following is supported by the data in the figure?

   A. From 1800 to 1920, there was no change in either the human population or the number of extinctions.
   B. From 1800 to 1920, the rate of extinction was lower than was the rate of human population growth.
   C. From 1950 to 2000, the rate of human population growth was inversely related to the rate of increasing extinctions.

D. From 1950 to 2000, the rate of human population growth and the hunting of species caused the increasing extinctions that occurred during the same period.

2. The figure indicates that the rate of change in the size of the human population was not constant from 1800 to 2010. Estimate the yearly average rate of change of the human population from 1800 to 1950 and from 1950 to 2010.

   A. From 1800 to 1950, the average rate of change of the human population was 1.5 billion people per year while from

1950 to 2010 the average rate of change was 5.5 billion per year.

B. From 1800 to 1950, the average rate of change of the human population was 1 million people per year while from 1950 to 2010 the average rate of change was 5 million per year.

C. From 1800 to 1950, the average rate of change of the human population was 10 million people per year while from 1950 to 2010 the average rate of change was 75 million per year.

D. From 1800 to 1950, the average rate of change of the human population was 100 million people per year while from 1950 to 2010 the average rate of

change was 500 million per year.

3. AP® Biology students examining the graph hypothesize that the rate of nonhuman species extinction depends on the size of the human population. Predict which of the following would be correct if the null hypothesis fails to be rejected.

   A. Both the human population and the rate of extinction continue increasing.
   B. The human population declines and the rate of extinctions declines.
   C. The human population stops increasing and the rate of

extinctions stops increasing.

D. The human population stops increasing but the rate of extinctions continues increasing.

4. Ecologists studied the presence of a small mammalian genus that exists across Earth, excluding Antarctica. They observed that a different species within this genus lives on each of the six continents. However, on five of the continents, the species of this genus share many more traits among themselves than they do with the species on the sixth continent. Which of the following best explains these observations?

A. All species of the genus are niche specialists.
B. Species of the genus are not capable of migration.
C. The sixth continent separated from the others earlier than the remaining continents separated from one another.
D. Species of the genus present on the five continents adapted better to their environments than did the species of the sixth continent.

5. Ecologists studying the evolutionary history of two species of pine trees hypothesize that the two species expanded their ranges by moving northward in North America after

the end of the last ice age. If species A expanded its range northward at a faster rate than species B, which of the following would be correct about the pollen grains found in the northern lakes?

A. Pollen grains of only species A would be found in the lake sediments.
B. Pollen grains of species A would be found in the same lake sediments as those of species B.
C. Pollen grains of species A would be found in deeper lake sediments than those of species B.
D. Pollen grains of species A

would be found in shallower lake sediments than those of species B.

Section 2: Free-Response Question

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

The pied flycatcher (*Ficedula hypoleuca*) is a migratory bird that spends winters in Africa and then migrates to Europe to breed in the spring. The great tit (*Parus major*) is another species of bird that lives in Europe year-round. The two bird

species compete for a limited number of nesting sites. Over the past 20 years, global temperature increases have produced warmer winters in Europe, which have resulted in earlier availability of good nesting sites and food sources for both species of birds. Scientists recorded the average December temperature for 5 years and the proportion of high-quality nest sites that were occupied by great tits before pied flycatchers migrated back to Europe each year. The data the scientists obtained is shown in the figure.

a. **Identify** the proportion of high-quality nest sites that were

occupied by *P. major* when the average December temperature was 2.5°C.

b. **Calculate** the difference between the maximum and the minimum observed nest site occupancies by *P. major* over the study period.

c. **Describe** the relationship between the mean December temperature and the proportion of nest sites that are occupied by *P. major*. **Make a claim** to explain this relationship.

d. Scientists have observed that the timing of pied flycatcher migration from Africa to Europe does not change, regardless of the local weather conditions in Europe. **Predict** the consequence

for the pied flycatcher population if European winter temperatures continue to increase.

AP® Practice Questions

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–15.

1. A population of 180 marine iguanas lives on the Galápagos Islands and has a carrying

capacity of 500 individuals. In one year, the population grew to 230. What is the maximum population growth rate (rmax)$(r_{\max})$?

A. 0.16
B. 0.29
C. 0.40
D. 0.46

2. In the 1980s and 1990s, overfishing by humans caused a significant decrease in the cod population in the northwest Atlantic. Predict how the removal of this predator affected the abundance of other species, such as small fish and shrimp, which are consumed by cod, and zooplankton, which are

consumed by the small fish.

A. Small fish, shrimp, and zooplankton all increased in abundance.
B. Small fish and shrimp increased in abundance while zooplankton decreased in abundance.
C. There was no effect on the abundance of the other species because other predatory fish species filled the niche of cod.
D. There was increased competition between small fish and shrimp for zooplankton, decreasing overall biodiversity.

3. The following table shows the

growth of a bacteria population in an experiment.

Hours	Number of bacteria
1	20
2	50
3	120
4	270
5	600

Which statement is supported by the data in this table?

A. The per capita growth rate (r) is greater than zero.
B. The max per capita growth rate (rmax)$(r_{\max})$ is very small in magnitude.
C. The carrying capacity is 600 bacteria.
D. The population is experiencing growth constraints.

4. Which species interaction correctly depicts a relationship between a heterotroph and an autotroph?

   A. The parasitism of a parasitoid wasp and a caterpillar
   B. The competition between tall trees and shorter ferns for light
   C. The predation of a fish consuming mosquito larvae
   D. The herbivory of a koala eating eucalyptus leaves

Use the following information to answer question 5.

Feral cats are wild cats that were once domesticated or descended from domesticated cats. In Australia, feral

cats are responsible for the extinction of numerous mammal species. One suggestion to control the feral cat population is to introduce dingoes, which are carnivorous mammals that prey on small mammals, to areas infested with feral cats. The hope is that dingoes will prey on feral cats and reduce their population.

1. Which of the following could be a concern about introducing dingoes to control the feral cats?

   A. Dingoes may prey upon threatened species in the habitats to which they are introduced.
   B. Dingoes may greatly reduce or eliminate the feral cat

population in the habitats to which the dingoes are introduced.

C. Dingoes will accelerate the feral cat elimination of native mammal species.

D. Dingoes will accelerate the extinction of native plant species.

Use the following information to answer question 6.

Scientists measured the abundance of insects, mammals, birds, and plants at several sites of different temperatures. They were able to calculate the Simpson's diversity index values for each site, as shown in the following graph.

1. What overall conclusion can be drawn from these data about the biodiversity of these sites?

   A. Biodiversity decreases as temperature increases.
   B. Mid-range temperatures support the greatest biodiversity.
   C. Biodiversity increases as temperature increases.
   D. Extremely cold and extremely warm temperatures have the greatest biodiversity.

Use the following figure to answer question 7.

Data from https://www.researchgate.net/publication/341350203_Causes_of_Mortality_in_a_Harbor_Seal_Phoca_vitulina_Population_at_Equilibrium

1. The graph shows a population growth curve for harbor seals in the San Juan Islands. Which statement is true of point A on the curve?

   A. Competition between seals is at its highest.
   B. Exponential growth is occurring.
   C. Linear growth is occurring.
   D. The death rate is greater than

the birth rate.

2. Which is a good indicator that an ecosystem is likely to have high resilience to an environmental disturbance?

   A. High biodiversity
   B. High productivity
   C. High intrinsic value
   D. High species evenness

3. Which statement is true regarding the difference in metabolic rate between a zebra and a rabbit?

   A. Larger animals require more food per kilogram of weight because of their higher surface area-to-volume ratio.
   B. Zebras are physically larger

than rabbits and must consume more food to provide energy for everyday activities.

C. The metabolic rate of the animals is a negative correlation; the rate decreases as the animals increase in size.

D. The difference in metabolic rate between zebras and rabbits is minimal because both are considered endotherms.

4. Large populations with high genetic diversity are more likely to

A. be resilient to natural or human-caused disturbances.

B. be outcompeted by invasive

species.

C. suffer great losses due to harmful pathogens or fungi.

D. experience the effects of a trophic cascade.

5. Robert Paine conducted a famous experiment involving the removal of the starfish *Pisaster* from their environment on the Washington state seacoast. This caused an increase in barnacles and mussels, which crowded out many other herbivores and algae species. Which statement supports these findings?

A. The removal of *Pisaster* represents a trophic cascade that began from the bottom

and worked its way up through the trophic levels.

B. The number of species present without *Pisaster* is low only because of direct effects.

C. *Pisaster* is a keystone species responsible for the collapse of diversity in the ecosystem when it is removed.

D. A disturbance was created by removing *Pisaster* from the ecosystem, but the number of species will return to normal through the process of succession.

Use the following information to answer question 12.

African elephants are a vital member

of the grassland ecosystem. They consume saplings, which maintains the grassland habitat and prevents it from becoming a woodland area. This provides a steady supply of grass for herbivores to graze and thus high prey numbers for large predator species. The following graph shows the data collected from an African savanna reserve, counting the number of species within its bounds during a 20-year time span.

1. Which population has significantly changed in size between 2000 and 2020?

   A. African elephants

B. Lions

C. Impala

D. Woody trees

Use the following information to answer question 13.

Ecologists study three animal species living on a tract of land, species A, B, and C. They track the number of offspring born to each female and the number of the offspring that survive to sexual maturity. The data collected are listed in the table.

Species	Average number of offspring born per female	Number of offspring that survive to sexual maturity
A	44	3
B	3	3
C	36	2

1. Which is a *K*-selected species?

   A. Species A
   B. Species B
   C. Species C
   D. Species A, B, and C

Use the following information to answer question 14.

Researchers examined the resistance of the bacterium *Streptococcus pneumoniae* to the antibiotics co-trimoxazole and erythromycin over a 10-year period. The results are shown in the figure.

Data from https://ars.els-cdn.com/content/image/1-s2.0-S1473309908700173-gr3_lrg.jpg

1. Which of the following do the data support?

   A. Resistance to either co-trimoxazole or erythromycin was not present in these bacterial populations prior to 1994.
   B. The bacteria were initially more resistant to erythromycin than co-trimoxazole.
   C. The percentage of bacteria resistant to erythromycin has declined over the 10-year period but the percentage of bacteria resistant to co-trimoxazole has increased over

the same time period.

D. The percentage of bacteria resistant to co-trimoxazole and erythromycin has increased over the 10-year period.

2. A species of weed has a maximum per capita growth rate of 0.3 per month. If the weed species is experiencing exponential growth and the population size is 20 weed plants, what will the population size be in 3 months?

   A. 26 weed plants
   B. 34 weed plants
   C. 44 weed plants
   D. 78 weed plants

Section 2: Free-Response

Questions

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

1. The Glanville fritillary (*Melitaea cinxia*) is a butterfly that lives in a patchy environment in Finland. Because of frequent environmental change, new patches of habitat regularly appear. These patches are colonized by migrant butterflies, which establish a small local population that grows to the carrying capacity of the patch. Scientists have observed the

growth dynamics of Glanville fritillary in one particular patch (patch A) since the habitat appeared. They observed the number of butterflies every year in Glanville fritillary in patch A and obtained the data shown in the following figure.

Using these data, they estimated that the maximum growth rate of a Glanville fritillary population is rmax = 0.63 $r_{\max} = 0.63$. While the scientists were collecting their

data, a second habitat patch appeared (patch B). The second patch was colonized by 26 butterflies during the first year, and the scientists estimated that it has a carrying capacity of 125 butterflies. The scientists assume that the rmaxr_{max} value for patch B is the same as the value for patch A.

a. Based on the data provided, **identify** the carrying capacity of patch A.
b. Based on the data provided, **predict** the number of Glanville fritillaries that are expected to be observed in patch B one year after it was colonized.

c. **Explain** why populations grow at slower rates when their population sizes are slightly lower than the carrying capacity than they do when their population sizes are much lower than the carrying capacity.

2. The following figure illustrates a food web showing trophic relationships between species in a field. The table following the food web shows the number of times each species was observed in a 1-km2$1\text{-km}^2$ area of the field.

Morris, et al., Biology for the AP® Course, 1e. © 2022 BFW High School Publishers

Species	Number of individuals in sampling area
Panicum virgatum	1863
Impatiens capensis	367
Peromyscus maniculatus	295
Sylvilagus floridanus	118
Odocoileus virginianus	26
Vulpes vulpes	18
Canis latrans	10
Buteo jamaicensis	4
Total	**2701**

a. **Identify** one species in the food web that is most likely a producer.
b. **Predict** the effect that removing *Vulpes vulpes* from this ecosystem would have on the abundance of *Panicum virgatum*. **Provide reasoning** to support your prediction.
c. **Identify** two organisms in the food web that are likely to

compete with each other.

d. Assuming the organisms shown in the food web and the table include all the major species in this ecosystem, **calculate** Simpson's diversity index for this ecosystem.

Cumulative AP® Biology Practice Exam

PREP FOR THE AP® EXAM

Section 1: Multiple-Choice Questions

Choose the best answer for questions 1–60.

1. Identify the main source of oxygen gas in Earth's atmosphere.

   A. Natural geologic processes

   B. Photosynthesis by plants,

algae, and bacteria

C. Fermentation by microorganisms

D. Decay of organic material

2. Extremophiles are microorganisms that live in environments characterized by extreme temperature, acidity, salt concentrations, or pH. Many extremophiles that live in high-temperature environments without oxygen perform anaerobic cellular respiration with an electron transport chain that uses iron or sulfides as terminal electron acceptors instead of oxygen. Which of the

following explains why this form of cellular respiration is observed in extreme environments without oxygen?

A. The extremophiles needed to obtain additional energy from glucose so they learned to use alternative electron receptors for respiration.

B. The iron and sulfides created a toxic environment so the extremophiles evolved anaerobic cellular respiration to detoxify their surroundings.

C. Extremophiles that evolved anerobic cellular respiration had a competitive advantage

over other microbes and were able to persist in the environment.

D. The extremophiles did not have organelles so they established an electron transport chain in the cell membrane.

Use the following table to answer question 3.

1. A portion of a protein is encoded by the following mRNA sequence.

   5 ′ … AUU GCA A _ GA UCC AGC … 3 ′

   5′ … AUU GCA AGA UCC AGC … 3′

   Which of the following

statements correctly predicts the consequence of a mutation that changes the underlined A to a U?

A. The mutation would result in a substitution of a different amino acid at the codon position and might change the function of the protein.

B. The mutation would change the mRNA sequence but would not change the protein sequence or function.

C. The mutation would reduce the length of the polypeptide and could change or eliminate protein function.

D. The mutation would change

the mRNA expression level and could change protein function.

Use the following information to answer questions 4–6.

As illustrated in the figure below, most plants absorb water from the soil through their roots and then use that water in biochemical reactions. Water vapor is released from plant leaves into the atmosphere through a process called transpiration.

1. Identify a biochemical process in plants that requires water as a reactant.

   A. Dehydration synthesis to form

starch

B. Hydrolysis of starch into simple sugars

C. Aerobic respiration

D. Anaerobic fermentation

2. The driving force for transpiration is the difference in water potential between the soil and the atmosphere surrounding the plant. Which of the following statements best describes the potential for water movement as illustrated in the figure?

A. The water potential in the soil is higher than the water potential in the roots, which

causes water to move from the soil into root cells.

B. The water potential in the roots is higher than the water potential in the soil, which causes water to move from the roots into the stem of the plant.

C. The water potential in the stem of the plant is higher than the water potential in the roots, which causes water to distribute into the leaves.

D. The water potential in the atmosphere is higher than the water potential in the leaves, which causes water vapor to

evaporate from the leaves.

3. Changes in the environment can affect the efficiency of transpiration. Which of the following statements accurately pairs an environmental change with a prediction about water movement?

   A. Decreasing water concentration in the air is predicted to slow water movement through the plant, thus slowing the rate of transpiration.

   B. Decreasing the number of leaves on the plant is predicted to decrease the water potential

in the leaves and therefore decrease the rate of transpiration.

C. Increasing the amount of water in the soil is predicted to increase the rate of water movement into the roots and therefore increase the rate of transpiration.

D. Increasing the volume of the plant will decrease the water potential of the stem and is therefore predicted to increase the rate of transpiration.

Use the following figure to answer question 7.

1. Which best illustrates nucleotide base pairing in a strand of DNA?

   A. a

   B. b

   C. c

   D. d

2. An organism called species X is observed to have a small population size relative to other species in an ecosystem. Scientists experimentally removed species X from the ecosystem and observed very large effects on the population sizes of other species in the system. Which of the following

statements best describes species X?

A. Species X is a primary producer that supplies most of the energy for other species in the system.

B. Species X is an essential species that increases the evolutionary fitness of other species in the system.

C. Species X is a keystone species that is critical for ecosystem stability.

D. Species X is a top predator that decreases the population size of producers in the system.

Use the following information to answer questions 9 and 10.

In a population of damselflies, there are two alleles of the *Est* gene: E S t F ESt^F and E s t S Est^S. A scientist collected 120 damselflies from a natural population and determined their *Est* genotypes. The scientist obtained the data shown in the table. The scientist used these data to test whether the population was in Hardy–Weinberg equilibrium.

Genotypes Obtained from 120 Damselflies

Genotype	E s t F Est^F E s t F Est^F	E s t F Est^F E s t S Est^S	E s t S Est^S E s t S Est^S

Number of individuals	6	46	68

1. Calculate the expected number of E s t F Est^F E s t S Est^S individuals in the population if the population is in Hardy–Weinberg equilibrium.

   A. 13

   B. 46

   C. 44

   D. 55

2. Calculate the chi-square test statistic that describes the goodness of fit of the observed genotype data to Hardy–Weinberg expectations.

A. 0.01

B. 0.42

C. 2.99

D. 0.26

3. Mammalian guts contain complex microbiological communities that differ in their biological properties. *Salmonella enterica* is one bacterium that is commonly found in the human gut. *Proteus mirabilis* is also found in the human gut. Some strains of *S. enterica* are highly resistant to multiple antibiotics, including an antibiotic called chloramphenicol. Chloramphenicol is very effective

at killing strains of *P. mirabilis* that are found in the environment. However, in an atypical case, scientists isolated both *S. enterica* and *P. mirabilis* from the gut microbial community of a single human patient and discovered that both bacteria were resistant to chloramphenicol. Which of the following claims provides the best explanation for the observed resistance to chloramphenicol by the atypical strain of *P. mirabilis*?

A. *P. mirabilis* acquired DNA from *S. enterica* in the patient's gut, which made the *P. mirabilis* resistant to chloramphenicol.

B. *P. mirabilis* absorbed detoxification enzymes from *S. enterica* in the patient's gut, which enabled the *P. mirabilis* to degrade the chloramphenicol.

C. *S. enterica* degraded the chloramphenicol in the patient's gut so it could no longer kill the *P. mirabilis*.

D. *S. enterica* activated gene expression by *P. mirabilis* in the patient's gut, which made the *P. mirabilis* resistant to chloramphenicol.

4. Identify which of the following double-stranded DNA molecules

would require the greatest energy input to be separated into single strands.

A. A double-stranded DNA molecule that is 30% cytosine

B. A double-stranded DNA molecule that is 25% thymine

C. A double-stranded DNA molecule that is 20% guanine

D. A double-stranded DNA molecule that is 15% adenine

Use the following figure to answer question 13.

1. The figure shows the transport of

three different molecules across a membrane. Each molecule is represented by a different shape. Which of the following statements correctly describes the movement of the molecules across the membrane?

A. The circular molecule is able to pass through the membrane by simple diffusion.

B. The triangular molecule is actively transported through a protein channel against its concentration gradient.

C. The square molecule is passively transported through a protein channel against its

concentration gradient.

D. All three molecules require energy input in order to cross the membrane.

Use the following information to answer questions 14 and 15.

Betta splendens is a popular species of aquarium fish. Body color in *B. splendens* is determined by a gene that has two alleles, *C* and *c,* where the *C* allele is dominant and results in a dark body color. The recessive *c* allele results in a light body color. A different gene with two alleles, *T* and *t,* determines the shape of the fish's tail. The *T* allele is dominant and results in a tail with a single large

lobe. The *t* allele is recessive and results in a tail that is split into two lobes. A male fish with the genotype *Cc TT* is crossed to a female fish with genotype *cc Tt*.

1. Identify the phenotype of the parental male fish in the cross.

   A. Dark body and single-lobed tail

   B. Light body and single-lobed tail

   C. Dark body and two-lobed tail

   D. Light body and two-lobed tail

2. Calculate the percentage of progeny from this cross that are expected to have two-lobed tails.

A. 0%

B. 33%

C. 50%

D. 100%

Use the following figure to answer question 16.

1. A chaotropic agent is a chemical that can disrupt the structure of nucleic acids by interfering with hydrogen bonding. Identify the letter on the figure that corresponds to the bonds that a chaotropic agent is most likely to disrupt.

A. A

B. B

C. C

D. D

Use the following information to answer questions 17–19.

The common buzzard (*Buteo buteo*) is a bird of prey whose color is determined by a mutation in the autosomal *mc1r* gene. Buzzards that are homozygous for the m c 1 r + $mc1r^{+}$ allele have a tan color, buzzards that are homozygous for the m c 1 r m u t $mc1r^{mut}$ allele have a black color, and heterozygous buzzards are brown. In the

population, 43% of the birds are tan, 20% of the birds are black, and 36% of the birds are brown. There is no difference between males and females in color frequency. Scientists observed 366 randomly chosen buzzard breeding pairs and recorded the color of the parents. The data they obtained are shown in the table.

		Female parent		
Male parent		Tan	Brown	Black
Tan	108	30	1	
Brown	29	124	19	
Black	3	19	33	

1. Based on the information provided, calculate the frequency of the m c 1 r m u t $mc1r^{mut}$ allele

in the population.

A. 0.38

B. 0.45

C. 0.60

D. 0.66

2. Based on the information provided, predict the percentage of offspring that are expected to be tan from a breeding pair composed of a tan female and a brown male.

A. 0%

B. 25%

C. 50%

D. 75%

3. Based on the information provided, identify the assumption underlying Hardy–Weinberg equilibrium that is most likely to be violated in this system.

   A. No mutation

   B. No natural selection

   C. Random mating

   D. No migration or gene flow

4. Which of the following statements correctly describes energy flow in an ecosystem?

   A. All the energy from lower levels of the system is available

to higher levels in the system.

B. The producer level directly provides energy to each of the higher levels in the system.

C. Energy is transferred directly from primary consumers to secondary consumers in the system.

D. The highest level of consumer in the system holds the highest amount of energy in the system.

5. Which of the following best describes the flow of free energy within the cells of a eukaryotic organism?

A. Catabolic reactions → oxidative phosphorylation → NAD + NAD^+ reduction → anabolic reactions

B. Catabolic reactions → NAD + NAD^+ reduction → oxidative phosphorylation → anabolic reactions

C. Anabolic reactions → NAD + NAD^+ reduction → oxidative phosphorylation → catabolic reactions

D. Anabolic reactions → oxidative phosphorylation → NAD + NAD^+ reduction → catabolic reactions

Use the following figure to answer

question 22.

1. The cell cycle is controlled by a complex interaction of molecules, including cyclins and cyclin-dependent kinases (CDKs), that coordinate key events within the cycle. Three major checkpoints, regulated by internal and external signals, determine whether the cell will advance through the cycle. Certain conditions must be met in order to form, activate, and then inactivate the cyclin-dependent kinases. The figure illustrates part of the molecular interactions that determine activation and inhibition of the

cycle. Based on the information provided, identify the statement that accurately describes the molecular interactions governing the cell cycle. Note that regular arrowheads indicate activation, and T arrowheads indicate inhibition.

A. Wee1 inhibitors will block the activity of Cdc25 when they are present in the cell, and will inhibit entry of the cell into mitosis.

B. The inactive form of CDK cyclin can be activated in the presence of CHK1.

C. Activated CDK cyclin

molecules prevent activation of Cdc25.

D. The presence of Wee1 molecules blocks the progress of the cell cycle by inhibiting DNA replication.

Use the following information to answer question 23.

A researcher has been studying chemical X, which is hypothesized to change the rate of cell division. To test this hypothesis, the researcher set up two samples of identical cell types. The cells in sample 1 were not exposed to chemical X. The cells in sample 2 were exposed to chemical X. The researcher counted the number

of cells in interphase and M phase in a sample of 125 cells from each treatment. The data the researcher obtained are shown in the table. The researcher used these data to perform a chi-square test to determine whether the number of cells undergoing mitosis changes significantly after exposure to chemical X.

	Number of cells in interphase	Number of cells in M phase
Sample 1 (no chemical X)	113	12
Sample 2 (chemical X applied)	79	46

1. Which of the following is the most appropriate null hypothesis

for this experiment?

A. If the cells are treated with chemical X, there will be an increase in the number of cells in mitotic phase.

B. If the cells are treated with chemical X, there will no change in the number of cells in mitotic phase.

C. If the cells are not treated with chemical X, there will be a decrease in the number of cells in interphase.

D. If the cells are not treated with chemical X, there will be no change in the number of cells in interphase.

2. Which of the following correctly describes the role of the enzyme DNA ligase in DNA replication?

   A. Ligase relaxes the structure of the DNA molecule so it can be accessed by DNA polymerase.

   B. Ligase separates the strands of the DNA molecule so DNA polymerase can copy the template strand.

   C. Ligase links the nucleotides bound by DNA polymerase in order to form the sugar–phosphate backbone of the newly copied DNA.

   D. Ligase connects short fragments of copied DNA to

form a longer continuous DNA strand.

Use the following figure to answer question 25.

1. In animals, the inner surface of the small intestine absorbs nutrients like sugars and amino acids from digested food. The cells of the inner lining of the intestine have long projections called microvilli that extend into the lumen where the food passes, as shown in the figure. Which of the following statements best explains role of the microvilli?

   A. The microvilli create a physical

structure that slows the passage of food through the intestine in order to increase opportunity for nutrient absorption.

B. The microvilli create a barrier that protects the intestinal cells from pathogens and harmful molecules in the food.

C. The microvilli create a larger surface area without significantly increasing the volume of the intestinal cells so that nutrients can be absorbed more efficiently.

D. The microvilli create membrane barriers that slow

the diffusion of digested food in order to increase the absorption of nutrients.

2. Maltase is an enzyme that breaks the sugar maltose into glucose monomers through a chemical reaction called hydrolysis. Which of the following statements best explains the requirement for maltase in the hydrolysis of starch?

   A. Hydrolysis requires an input of energy, and the maltase enzyme supplies that energy.

   B. Hydrolysis releases energy, and the maltase enzyme absorbs the released energy.

C. Hydrolysis is a spontaneous reaction, and the maltase enzyme makes the reaction happen more quickly.

D. Hydrolysis reduces entropy, and the maltase enzyme enables the reaction by stabilizing the products.

Use the following figure to answer question 27.

1. The figure illustrates part of a food web of species in Redwood National Forest. Based on the relationships shown, predict the most likely result of removing the northern spotted owl.

A. There would be an increase in the number of northern flying squirrels and a decrease in the amount of blue elderberry.

B. There would be an increase in the number of great horned owls and an increase in the number of Douglas squirrels.

C. There would be an increase in the number of big brown bats and an increase in the number of wood boring beetles.

D. There would be a decrease in the number of Douglas squirrels and an increase in the number of grasshoppers.

2. Which of the following

statements correctly describes photosynthesis?

A. Photosynthesis occurs only in green plants and algae.

B. Photosynthesis evolved in bacteria and was subsequently acquired by plants.

C. Photosynthesis evolved independently in prokaryotes and plants.

D. Photosynthesis evolved in plants and was subsequently acquired by bacteria.

3. *Daphnia cucullata* are small aquatic crustaceans that are preyed upon by *Chaoborus*

flavicans. *C. flavicans* secretes chemicals known as kairomones into water. When *C. flavicans* kairomones are present, *D. cucullata* develop a large structure known as a helmet. The helmet makes the *D. cucullata* too large to fit into the mouth of *C. flavicans* and therefore protects the *D. cucullata* from predation by *C. flavicans*. The helmet is not produced if there are no *C. flavicans* kairomones in the water. Which of the following statements best explains why *D. cucullata* does not produce a helmet in the absence of *C. flavicans* kairomones?

A. The helmet is constructed

from kairomones, so *D. cucullata* cannot produce it when the kairomones are not present.

B. Kairomones bind to *D. cucullata* DNA and activate expression of genes required to develop the helmet, so the helmet can only be produced when kairomones are present.

C. The helmet is costly to produce, so the *D. cucullata* would have lower fitness if they developed it when it is not necessary.

D. The helmet is a signal to predators that they should not

eat the *D. cucullata*, so the *D. cucullata* choose not to make the helmet when *C. flavicans* are absent.

Use the following figure to answer question 30.

1. Serine is an amino acid that may be found on the hydrophilic interior of a protein channel. The structure of serine is shown in the figure. Identify the atoms in serine that are responsible for its hydrophilic properties.

   A. H 2 N H_2N

   B. H

   C. COOH

D. CH 2 OH CH_2OH

2. Identify the RNA sequence that would be transcribed from this DNA template strand:

5 ′ -CTC GTA GCC CGA- 3 ′

5′-CTC GTA GCC CGA-3′

A. 5 ′ -CUC GUA GCC CGA- 3 ′

5′-CUC GUA GCC CGA-3′

B. 5 ′ -UCG GGC UAC GAG- 3 ′

5′-UCG GGC UAC GAG-3′

C. 5 ′ -TCG GGC TAC GAG- 3 ′

5′-TCG GGC TAC GAG-3′

D. 5 ′ -GUG CUT CGG GCT- 3 ′

5′-GUG CUT CGG GCT-3′

Use the following information to

answer question 32.

An investigator is studying dividing cells from the lymph node of a patient. The investigator uses a fluorescent DNA stain to quantify the relative amount of DNA in each cell from the lymph tissue. The figure is a schematic representation of DNA content in one of the cells of the lymph node, where n represents the content of DNA that would be found in a haploid gamete.

DNA content per cell during the cell cycle

1. Identify the statement that pairs a claim about the graph with correct supporting reasoning.

A. The cell is in the mitotic phase during time interval I and therefore has half as much DNA as during other time intervals.

B. Interphase occurs exclusively in time interval III, when the amount of DNA does not change prior to cell division.

C. The cell is actively replicating its DNA during time interval II so the amount of DNA increases from $2n$ to $4n$.

D. The cell represented in the graph is undergoing meiotic division and the change in the amount of DNA between time

interval I and time interval IV indicates two cell divisions.

2. Typical eukaryotic cells range in size from 10 to 100 micrometers in diameter. If a spherical cell with a diameter of 50 micrometers divides into two daughter cells, each of which has half the volume of the parent cell, how would the surface area-to-volume ratio of one daughter cell relate to that of the parent cell?

   A. The surface area-to-volume ratio of the daughter cell would be approximately 25% larger than that of the parent cell.

   B. The surface area-to-volume

ratio of the daughter cell would be approximately 2.5 times larger than that of the parent cell.

C. The surface area-to-volume ratio of the daughter cell would be approximately double that of the parent cell.

D. The surface area-to-volume ratio of the daughter cell would be approximately half that of the parent cell.

3. Which of the following best predicts the consequence of a chemical that disrupts the thylakoid membrane of a chloroplast and makes it

permeable to protons (H +) (H^+)?

A. There would be increased accumulation of NADPH.

B. There would be increased production of O 2 O_2.

C. There would be decreased production of ATP.

D. There would be decreased production of CO 2 CO_2.

4. The corn borer (*Ostrinia furncalis*) is a major insect pest of corn crops in the United States. A research team was attempting to produce an insecticide to kill corn borers. The team discovered that

chemical Y makes the inner mitochondrial membrane leaky to H + H^+ ions. Which of the following statements best predicts the outcome of applying chemical Y to corn borers?

A. Corn borer cells will be unable to couple the oxidation of glucose molecules with the reduction of NAD + NAD^+ to NADPH, which will prevent cellular respiration and cause the corn borers to die.

B. Corn borer cells will be unable to couple the breakdown of high-energy phospholipids in the mitochondrial membrane with regeneration of NADH

molecules, which will inhibit cellular respiration and cause the corn borers to die.

C. Corn borer cells will be unable to couple the hydrolysis of ATP to the creation of H 2 O H_2O during oxidative phosphorylation, which will inhibit hydrolysis reactions required for cellular metabolism and cause the corn borers to die.

D. Corn borer cells will be unable to couple the generation of a proton gradient to the production of ATP, so the cells will produce heat energy instead of chemical energy and

the corn borers will die.

5. An aquatic ecosystem is susceptible during the summer to massive growths of blue-green algae, known as harmful algal blooms (HABs). HABs pose a threat to drinking water supplies, outdoor recreation, and the health of animals who come into contact with the water. A scientist hypothesized that HABs might be caused by phosphorus input into aquatic ecosystems from agricultural runoff. Which of the following would be the most appropriate dependent variable in an experiment designed to test the researcher's hypothesis?

A. The health of fish and other aquatic animals in the ecosystem

B. The abundance of blue-green algae in the aquatic ecosystem

C. The degree of competition between blue-green algae and native plant species in the ecosystem

D. The concentration of phosphorus in the water in the ecosystem

Use the following information to answer questions 37–39.

The 10 steps in glycolysis are shown in Figure 1 below. A scientist

hypothesized that a chemical known as 3PO might inhibit glycolysis. To test this hypothesis, the scientist measured the levels of glucose, pyruvate, and three intermediate molecules in a flask of cells over a 90-minute period. The scientist added glucose to the flask to begin the experiment. After 30 minutes, the scientist added 3PO to the flask. After the second 30-minute interval, the scientist added additional glucose to the flask. The data the scientist obtained are shown in Figure 2.

FIGURE 1 Glycolysis

FIGURE 2 Levels of glucose, pyruvate, and three intermediate molecules over a

90-minute time interval

1. Calculate the rate of pyruvate production during the first 30 minutes of the experiment.

   A. 0.7 mmol/minute

   B. 1.7 mmol/minute

   C. 30 mmol/minute

   D. 60 mmol/minute

2. Identify the enzyme that is most likely to be inhibited by 3PO.

   A. Hexokinase

   B. Phosphoglucoisomerase

C. Phosphofructokinase

D. Aldolase

3. Identify the type of inhibition exhibited by 3PO.

A. Competitive

B. Allosteric

C. Irreversible

D. Covalent

4. A scientist determines that a nucleic acid is composed of 17% adenine, 23% uracil, 28% cytosine, and 32% guanine. Identify the structure of the nucleic acid.

A. Double-stranded DNA

B. Double-stranded RNA

C. Single-stranded DNA

D. Single-stranded RNA

Use the following information to answer questions 41 and 42.

The model shown in the figure illustrates how the human body maintains blood glucose homeostasis. The liver and the pancreas are organs in the body.

1. Based on the information provided, predict the effect of eating a large meal.

A. The insulin level in the blood will increase, followed by increased glycogen production by liver cells.

B. The insulin level in the blood will decrease, followed by an increase in glucose level in the blood.

C. The glucagon level in the blood will increase, followed by conversion of glycogen to glucose by liver cells.

D. The glucagon level in the blood will decrease, followed by an increase in glucose level in the blood.

1. Identify the graph above that best illustrates the relationship between the levels of insulin and glucagon produced by the pancreas as a function of glucose level in the blood.

   A. a

   B. b

   C. c

   D. d

2. Identify which organelle uses an electron transport chain to establish a proton gradient across a membrane.

   A. Mitochondrion

B. Golgi

C. Ribosome bound to endoplasmic reticulum

D. Nucleus

3. Photosynthesis is a complex metabolic pathway that utilizes oxidation–reduction reactions as a means of converting light energy to chemical energy. During the light reactions, NADP + $NADP^+$ is reduced to NADPH. Which of the following best describes the role of NADPH in the Calvin cycle?

A. NADPH is used to oxidize CO 2 CO_2, leading to the release of O 2 O_2 into the

atmosphere.

B. Energy from NADPH is used to synthesize ATP, which is then hydrolyzed to provide energy for synthesizing carbohydrates.

C. NADPH is an essential building block for carbohydrates, and supplies carbon and hydrogen atoms necessary for making sugars.

D. NADPH reduces organic molecules that are generated from CO 2 CO_2, and the reduced molecules are then converted to sugar.

4. Which of the following

statements best describes how small nonpolar signaling molecules are able to stimulate a cellular response?

A. Small nonpolar ligands bind to the extracellular domain of cell-surface receptors to initiate a G protein-coupled response.

B. Small nonpolar ligands diffuse through the cell membrane and interact with receptors found in the cytosol.

C. Small nonpolar ligands bind to the intracellular domain of cell-surface receptors and initiate a signal transduction

cascade.

D. Small nonpolar ligands bind to phospholipids embedded in the cell membrane and create channels that allow molecules to enter the cell.

Use the following figure to answer question 46.

1. Occasional errors in meiosis result in gametes that contain either too many or too few chromosomes. Embryos that are generated from these gametes typically do not survive. The figure illustrates gametes arising from one possible error in

meiosis. Identify the most likely step at which the error in meiosis occurred.

A. Anaphase I

B. Telophase I

C. Anaphase II

D. Telophase II

2. During periods of intense exercise, the levels of oxygen in a human muscle cell can become depleted and aerobic cellular respiration is suppressed. During these periods, glycolysis may continue to produce ATP through the conversion of glucose to pyruvate. Which of the following

statements best explains what happens to pyruvate in this situation?

A. Pyruvate is converted to lactic acid, which is then converted back to glucose to fuel glycolysis.

B. Pyruvate is converted to lactic acid, which is coupled with the oxidation of NADH, producing the NAD + NAD^+ required for glycolysis.

C. Pyruvate is converted to lactic acid, which is coupled with the phosphorylation of ADP, producing the ATP required for hydrolysis of glucose.

D. Pyruvate is converted to lactic acid, which is used as a source of molecular oxygen to restart cellular respiration.

3. Red foxes (*Vulpes vulpes*) typically have red fur. Occasionally they have silver fur. Fur color is coded for by a single gene and silver fur is dominant to red fur. A breeder crossed two foxes with silver fur, each of whom had one parent with red fur. The pair of silver foxes produced 19 offspring, 7 of which were red and 12 of which were silver. Which of the following statements best explains the observed proportion of red foxes in the offspring?

A. The allele that causes red fur is inherited independently of the allele that causes silver fur.

B. Red fur is determined by an epigenetic mutation that skips a generation.

C. The allele that causes silver fur displays its phenotype only when it is homozygous.

D. The allele that causes silver fur is lethal when it is homozygous.

4. Two closely related species of cricket, *Gryllus pennsylvanicus* and *Gryllus firmus*, live in geographic ranges that partially overlap. Male crickets rub their legs

together to make sound in a process known as stridulation. The sound is attractive to females, and the males use the sound as courtship songs to attract mates. Different cricket species make slightly different courtship songs. Females can mate with males of the other species, but the offspring that arise from these matings have lower fitness than the offspring of matings between males and females of the same species. Based on the data provided, which of the following statements best predicts the future evolution of courtship songs in these two species?

A. Mating between members of

the two species will cause the species to fuse into a single species that will evolve a shared courtship song.

B. Females from each species will evolve to recognize the song of the other species and avoid it, and the two species will evolve distinct courtship songs.

C. Males of each species will evolve to mimic the courtship song of the other species in order to attract as many females as possible.

D. Females of both species will evolve courtship songs of their own and will begin to attract

males.

Use the following figure to answer question 50.

1. Which of the following correctly describes the reaction illustrated in the figure?

   A. Hydrolysis of a polymer through the release of a water molecule

   B. Hydrolysis of a polymer through the addition of a water molecule

   C. Dehydration synthesis of a polymer through the release of a water molecule

D. Dehydration synthesis of a polymer through the addition of a water molecule

2. Which of the following is common in the generation of eukaryotic mRNA but not in the generation of prokaryotic mRNA?

A. Uridine (U) is used instead of thymidine (T).

B. Sequences encoding multiple proteins are produced in a single transcript.

C. A poly-A cap is added to the 5 ′ $5'$ end of the transcript.

D. Sequences that do not encode protein are removed from the

transcript.

Use the following information to answer questions 52 and 53.

Oxidative stress can cause damage to cells. Expression of the *Gpx2* gene is activated in response to oxidative stress. *Gpx2* encodes an antioxidant protein that reduces oxidative stress. Keap1 and Nrf2 are proteins that regulate the expression of *Gpx2* in response to oxidative stress, as shown in the figure. Regular arrowheads indicate activation, and T arrowheads indicate inhibition.

1. Based on the information provided, which of the following

statements correctly describes Nrf2?

A. Nrf2 is a transcriptional activator.

B. Nrf2 is a negative regulator of gene expression.

C. Nrf2 is an enzyme in a signaling pathway.

D. Nrf2 is a biochemical intermediate.

2. Based on the information provided, predict the effect of a mutation that eliminates activity of the Keap1 protein.

A. The cell will continuously produce Gpx2 protein and

therefore will continuously experience oxidative stress.

B. The cell will be unable to express the *Gpx2* gene and therefore will be unable to respond to oxidative stress.

C. The cell will be unable to regulate the activity of Nrf2 and therefore will have a high level of protection against oxidative stress.

D. The cell will be unable to suppress the activity of Keap1 and therefore will be highly sensitive to oxidative stress.

3. A population of 125 pheasants (*Phasianus colchicus torquatus*) was

introduced to a small island off the coast of Washington State. After one year, the population had grown to 175 individuals. The estimated carrying capacity of the island is 250 pheasants. Based on the data provided, calculate the maximum population growth rate, r max $r_{\max}$, for the year.

A. 0.29

B. 0.40

C. 0.57

D. 0.80

Use the following figure to answer question 55.

1. A scientist added five grains of rice to 100 mL of sterile water and allowed the mixture to sit at room temperature for 24 hours. She then added 25 mL of pond water in which she had previously observed a small number of microorganisms, covered the dish, and made daily observations for 96 hours. After 24 hours, the scientist observed a rapid growth in the number of bacteria. After 72 hours, she observed a high number of *Chilomonas,* which is a microorganism that feeds on bacteria. After 96 hours, she observed a high number of *Paramecium,* which are a larger microorganism that eats

Chilomonas. Which diagram correctly illustrates the trophic relationships in this system?

A. a

B. b

C. c

D. d

Use the following diagram, which illustrates evolutionary relationships among seven species, labeled J–P, to answer questions 56 and 57.

1. Which species is most closely related to species M?

A. Species J

B. Species K

C. Species L

D. Species P

2. Identify the species that is the outgroup on the phylogenetic tree.

A. Species J

B. Species L

C. Species M

D. Species P

3. The brown marmorated stink bug, *Halyomorpha halys,* is native to Asia. In the late 1990s, a small

number were found in the northeastern United States. Since their introduction, populations in the United States have grown dramatically and they are now a threat to natural ecosystems and agriculture. One proposed strategy to control brown marmorated stink bug populations in North America is to introduce a species of parasitic wasp that naturally controls them in Asia. However, researchers considering this strategy are concerned that introducing the parasitic wasps might cause additional problems. Which of the following best predicts an environmental problem that

might occur if the parasitic wasps are introduced to areas with large populations of marmorated stink bugs?

A. The introduced wasps might evolve a preference for native stink bug species and have no effect on the brown marmorated stink bug.

B. Brown marmorated stink bugs in the United States might evolve new mechanisms to avoid the parasitic wasps.

C. Predators in the United States might prey on the wasps so they would not be effective at controlling brown marmorated

stink bugs.

D. The wasps may have no natural predators in the Unites States, so their population could become too large and compete with native species.

4. A team of researchers wanted to know the diversity of plants in a small woodland area. They set up a series of quadrats in a sampling area and counted the number of individuals of each species observed within the quadrats. The data obtained from one quadrat is shown in the table.

Species	**Abundance**
Wood-anemone *(Anemone quinquefolia)*	2

Carolina lupine *(Thermopsis villosa)*	8
Northern maidenhair fern *(Adiantum pedatum)*	1
Dwarf crested iris *(Iris cristata)*	1
Eastern blue star *(Amsonia tabernaemontana)*	3
Total	**15**

Based on the data provided in the table, calculate Simpson's diversity index for this quadrat.

A. 0.10

B. 0.35

C. 0.65

D. 0.90

5. Frogs of the species *Eleutherodactylus coqui* have brown bodies. Some individuals have light-colored stripes along the length of the body, and the presence of stripes is variable in the population. A scientist examined the striping patterns in a family of *E. coqui* individuals whose pedigree is shown in the figure below. Based on the data presented in the figure, identify the most likely mode of inheritance of the striped phenotype.

Data from https://academic.oup.com/jhered/article/101/6/703/1032960

A. Stripes are autosomal dominant.

B. Stripes are autosomal recessive.

C. Stripes are *X*-linked dominant.

D. Stripes are *X*-linked recessive.

Section 2: Free-Response Questions

Write your answer to each part clearly. Support your answers with relevant information and examples. Where calculations are required, show your work.

1. Chorismate is a chemical that can be converted into the amino acids tryptophan, phenylalanine, or tyrosine by the yeast *Saccharomyces cerevisiae*. The metabolic pathway that produces the three amino acids is shown in Figure 1 below. ANTH, PPA, PPY,

and HPP are intermediate molecules during the conversion, and Trp3p, Aro7p, Pha2p, and Tyr1p are enzymes in the pathway. Note that regular arrowheads indicate activation and T arrowheads indicate inhibition.

FIGURE 1 The metabolic pathway for production of tryptophan, phenylalanine, and tyrosine by *S. cerevisiae*

A scientist hypothesizes that the

amount of tryptophan available to *S. cerevisiae* cells will influence the amount of phenylalanine that the cells produce. The scientist grows five separate cultures of *S. cerevisiae* cells in culture medium. Four cultures are supplemented with different levels of tryptophan and one culture contains no additional tryptophan. The scientist measures the amount of phenylalanine produced by the cells in each culture and obtains the data shown in Figure 2. The amount of phenylalanine is measured in mmol per gram of *S. cerevisiae* cells, and the amount of supplemental tryptophan is

measured in μg per mL of culture medium. Error bars are calculated as ±1 standard deviation on either side of the mean.

FIGURE 2 The amount of phenylalanine produced by *S. cerevisiae* cells in the presence of different levels of supplemental tryptophan

a. Using the information provided in Figure 1, **explain** the role of tyrosine in the

pathway used by the cell to synthesize phenylalanine.

b. **State** the null hypothesis for the experiment performed by the scientist. **Identify** the negative control and the independent variable.

c. Using the information provided in Figure 2, **describe** the effect of adding supplemental tryptophan to the medium on phenylalanine production. **Calculate** the ratio of mean phenylalanine production when the medium is supplemented with 50 μg/mL of tryptophan to mean phenylalanine production

when the medium is supplemented with 25 μg/mL of tryptophan. Use the means and confidence intervals in Figure 2 to determine whether there is a statistically significant difference in phenylalanine production when the medium is supplemented with 100 μg/mL of tryptophan compared to when the medium is supplemented with 50 μg/mL of tryptophan, and **provide reasoning** to support your claim.

d. Assuming that chorismate is present in excess, **predict** how a mutation that eliminates the

function of Tryp1 would change the relationship between phenylalanine production and supplemental tryptophan added to the medium. **Provide reasoning** to justify your prediction.

2. The Trinidad guppy *Poecilia reticulata* is a fish that lives in freshwater streams in the Caribbean. Scientists studying *P. reticulata* in nature observed that guppies living in environments with a high density of predators use multiple behaviors to escape predation, but that guppies living in environments with few predators do not display those behaviors. The scientists captured

guppies from a region of a stream where there was a particularly high density of a predatory fish, the pike cichlid (*Crenicichla alta*), as well as from a different region of the same stream where pike are not present. The scientists brought the captured guppies from both locations into their laboratory and used them in two experiments.

In experiment 1, the scientists placed five guppies from the high-predation environment and five guppies from the low-predation environment into an aquarium that contained a single predatory pike. The scientists observed the tank until the predator had

consumed half of the guppies. The scientists recorded the environment from which each fish that was consumed had originally been collected. The scientists repeated this experiment five times.

In experiment 2, the scientists repeated the experimental procedure using offspring from fish captured in the high-predation environment and offspring from fish captured in the low-predation environment. All offspring were reared in the laboratory.

The data that the scientists collected from both experiments

are shown in the table below.

Experiment 1: Fish Captured in the Wild				
	Low-predation environment (mean)	Low-predation environment (standard deviation)	High-predation environment (mean)	High-predation environment (standard deviation)
Proportion preyed upon in the laboratory	0.81	0.12	0.19	0.10
Experiment 2: Offspring of Fish Captured in the Wild				
	Low-	Low-	High-	High-

	predation environment (mean)	predation environment (standard deviation)	predation environment (mean)	predation environment (standard deviation)
Proportion preyed upon in the laboratory	0.59	0.13	0.41	0.12

a. Scientists observed that guppies are more abundant than pike in regions of the stream where both species coexist. **Explain** why prey animals tend to have larger population sizes than their predators in most ecosystems.

b. **Construct** an appropriately labeled bar graph that illustrates the data from both

experiments in the table.

c. The scientists noted the difference in predation between the two populations of guppies in experiment 1 was greater than the difference in predation between the two populations of guppies in experiment 2. **Make a claim** to explain this result. **Provide reasoning** to support your claim.

d. A scientist claims that wild populations of guppies contain genetic variation for the ability to avoid predation. Based on the information provided, **support** the scientist's claim

with one piece of reasoning. Assuming the scientist's claim is correct, **predict** the short-term effect on the natural population of guppies if pike were introduced into the environment where they are currently absent. **Provide reasoning** to support your prediction. Additionally, **predict** the long-term effect on the natural population of guppies if pike were introduced into the environment where they are currently absent and **provide reasoning** to support your prediction.

3. Parasitoid wasps are insects that

lay their eggs inside the bodies of other insects, called hosts. The wasp eggs hatch into larvae that eat the host insect from the inside, killing the host. However, the host insect can sometimes kill wasp larvae with a successful immune defense.

A researcher established six populations of the host insect *Drosophila melanogaster,* which is a species of fruit fly. The researcher exposed three of these populations to parasitoid wasps, then collected the surviving *D. melanogaster* and bred them to establish the next generation. The researcher did not expose the other three populations to the

parasitoid wasps, and instead chose random individuals to breed for the next generation. The researcher repeated this process for eight generations.

In each generation, the researcher evaluated the ability of *D. melanogaster* from each population to defend themselves against parasitoid wasps. The researcher removed a sample of the *D. melanogaster* from each of the six populations and exposed them to parasitoids, recording the percentage that were able to mount a successful immune defense and survive. The data that the researcher obtained are shown in the figure. After eight

generations, the researcher also measured the average number of offspring produced by individual females each population in the absence of parasitoids. The researcher found that females from the populations that were repeatedly exposed to parasitoids over the eight generations produced fewer offspring than females from the populations that were never exposed to parasitoids.

a. **Describe** the role of genetic variation in evolution by natural selection.

b. **Justify** the use of the populations that were not exposed to parasitoids in the described experiment.

c. In the ninth generation, the researcher combined an equal number of individual *Drosophila* from each of the six populations into a single mixed population. Based on the information provided, **predict** how the ability to defend against parasitoids would

change in the mixed population after several generations of evolution without exposure to parasitoids.

d. **Justify** your prediction in part c.

4. Galactokinase is a yeast protein that is encoded by the *gal1* gene. Transcription of *gal1* is activated by the presence of galactose in the environment. Cycloheximide is a chemical that prevents protein translation when it is added to yeast cells.

   A scientist measured the level of *gal1* mRNA and galactokinase

protein in an actively growing yeast culture for 300 minutes. For the first 60 minutes of the experiment, the growth medium contained no galactose. After 60 minutes, the scientist added a high level of galactose to the medium. After an additional 140 minutes, the scientist replaced the growth medium with fresh medium that contained no galactose. The data that the scientist obtained are shown in the figure.

Amount of *gal1* mRNA transcripts

and galactokinase proteins per cell

a. **Identify** the organelle that produces galactokinase protein from *gal1* mRNA transcripts and a location in the cell where that organelle can be found.

b. **Explain** why there is a difference between galactokinase level and *gal1* mRNA level at 280 minutes in the experiment, after the galactose has been removed.

c. **Predict** the amount of galactokinase protein that would be observed at minute 200 in the experiment if

cycloheximide were added to the culture at minute 180.

d. **Justify** your prediction from part c.

5. Evening primrose (*Oenothera biennis*) is a small flowering plant that provides habitat for herbivorous and predatory insects. To test the effect of *O. biennis* genetic diversity on the abundance of insects associated with these plants, scientists planted experimental gardens that contained either one *O. biennis* genotype, four *O. biennis* genotypes, or eight *O. biennis* genotypes. Sixteen total plants were planted in each garden. The

scientists then counted the mean number of insects associated with each plant in the garden on five different days during the growing season. The data they obtained are shown in the figure. Error bars are calculated as ±1 standard deviation on either side of the mean.

Insect abundance in gardens with plants of varying genetic diversity

a. Using the data in the figure,

describe the change in insect abundance on the plants during the growing season.

b. **Identify** the sampling date that shows the largest difference in insect abundance between gardens planted with four genotypes and gardens planted with eight genotypes.

c. Before beginning the experiment, the scientists hypothesized that garden plots with genetically diverse *O. biennis* would support larger insect populations. Based on the information provided in the figure, **make a claim** about whether the data support or do

not support this hypothesis. **Provide reasoning** to support your claim.

d. Based on the information provided, **predict** which of the gardens are likely to support the greatest transfer of energy across trophic levels. **Explain** the reasoning behind your answer.

6. The diagram below illustrates the electron transport chain utilized in in the light reactions of photosynthesis.

a. **Describe** the role of light in photosystem II and photosystem I.

b. **Describe** the reason that the concentration of protons is higher in the thylakoid lumen than in the stroma.

c. **Identify** a location on the diagram where a protein converts potential energy into a stored chemical energy that can be used by the cell later.

d. **Explain** how the production of NADPH by the electron transport chain during photosynthesis supports the production of carbohydrates in

a plant cell.

Tutorial 4: Graphing

PREP FOR THE AP® EXAM

Introduction

Graphs serve as a useful visual tool for scientists to identify and analyze patterns in datasets that they have collected. It is often easier to see these trends in a graph, rather than as data in a table. There are several different kinds of graph, each with its own uses. As you will see, certain types of data are best suited for certain types of graphs.

In this tutorial, we will discuss some of the most commonly used graphs and how to decide when each is appropriate to use. This will serve as a guide to reading and interpreting the results of nearly every graph you encounter throughout this textbook and in your study of AP® Biology.

XY Graphs

The first type of graph that we will examine is the XY graph. Here, we will also cover the parts of a graph and how to construct one. Typically, a graph is created from data that have been organized into a table or chart, such as the following one. It is much easier to see trends visually presented in an XY graph than in a table. Graphs provide a way to quickly see patterns in data.

Example:

The following table and its associated graph show the relationship between the average height and diameter of the Douglas fir tree. Diameter measurements were taken 1.37 m from the ground. Total tree height was also measured.

Average diameter (cm)	7.6	12.7	17.8	24.6	27.9
Average height (m)	6.1	9.1	12.8	15.2	17.7

A basic graph, such as this one, is composed of two axes: the horizontal *x*-axis and the vertical *y*-axis. Each axis has its own label with units. In this example, the average diameter is on the *x*-axis and the average height is on the *y*-axis. Each

data point has one corresponding *x*-axis and *y*-axis value.

Graphs also feature a scale. The scale is the set of numbers written on each axis. In the graph of tree diameter and height, the scale for the *x*-axis goes from 0 to 30 cm and increases by increments of 5. The scale of the *y*-axis goes from 0 to 20 m and increases by increments of 2. Scales depend on the data that are collected. When you are tasked with creating a graph, you must decide what scale to use based on the data you are given. For example, if the data consist of the numbers 2, 3, 6, 8, and 10, it might be good to use a scale from 0 to 10 in increments of 1 or 2. If the data are not as numerically close together, you would create a scale with larger increments.

The orientation of the data is the direction in which the data are plotted along the axes. Generally, data points and values increase as they move up the *y*-axis and across the *x*-axis. Sometimes, the 0 point is the same for both axes and is located at the corner where those two axes meet, as in the graph to the left. Other times, the 0 point may be different for each axis. Occasionally, and especially if you are looking at a graph with multiple variables plotted, a graph will contain a key that notes the way that different datasets are depicted.

Each variable plotted on the *x*- or *y*-axis is labeled with the appropriate units. These are usually given as part of the axis label. In the graph above, the *x*-axis diameter is measured in centimeters. The *y*-axis height is measured in meters.

Whenever you are asked to give an answer regarding reading a point on a graph, make sure to include units.

Tables and graphs reveal trends or patterns. For example, in both the table and the graph of tree height and diameter, we can see that as the average diameter of the tree increases, the average height also increases. Sometimes these patterns are represented by a trend line or line of best fit. Trend lines can approximate the data in the graph and provide an even clearer picture of how the data are behaving. They can also be used for predicting the value of certain data points. In the graph of tree height and diameter, the trend line is depicted with a red line.

A trend line is an approximation of the data. Not every point has the line running exactly through it. We are trying to draw a line that best represents the pattern in the data. For this graph, it is straightforward because the data are so linear. The line should go through the middle of your data and have approximately the same number of data points below and above the line. Trend lines can be straight or curved.

Your Turn

During the spring, birds sing at early hours. A student decided to record the number of birds seen or heard between the hours of 4 a.m. and 9 a.m. The results are shown in the following table.

Time of day	4 a.m.	5 a.m.	6 a.m.	7 a.m.	8 a.m.	9 a.m.
Number	6	10	17	14	14	9

of birds						

Using this table, plot the data on a graph with proper axis labels and scales, and identify trends from this information.

Solution

To begin, let's identify the two types of data from the table. We have data about the time of day and data about the number of birds. We can plot time on the horizontal *x*-axis and number of birds on the vertical *y*-axis.

Next, we will determine the scale of the graph. There are only 6 points of data that will be plotted. The scale for the *x*-axis is simple enough: we can include each individual time as its own data point. The *y*-axis values range from a minimum of 6 to a maximum of 17. We

can begin our *y*-axis scale at 0. It is a good idea to choose an endpoint to the scale that is close to the maximum value. We could choose 18 or 20 to give ourselves more room to plot the data. Let's choose 20.

The next decision is to pick the increments of the scale. If our *y*-axis is going to range from 0 to 20, we have a few options. Because the numbers are relatively small, we could choose to increase the scale by increments of 1 (0, 1, 2, 3, and so on), but this can result in a cluttered graph. We want to make the data points as easy to read and interpret as possible. With this in mind, we could choose intervals of 2, 4, or 5. Again, because there is a small range of values in this dataset, any of these options would work. For the sake of having the

most uncluttered graph, we will use a *y*-axis scale that increases by 5. The graph now looks like the following figure.

With the axes labeled and scales set, we can plot the data in the table. It is best to plot as you progress across the *x*-axis. Mark one data point at a time and double-check that you have the correct *x* value paired with the correct *y* value. For example, at 4 a.m., there were 6 birds singing. Once you have plotted that point, move on to the next point. When you've finished, the graph should look like this:

The pattern in this dataset is clear. The points show that the most birds are

singing around 6 a.m., while fewer birds are singing earlier and later in the morning.

Bar Graphs

You are probably already familiar with bar graphs. They are a common way for researchers to present data and are often colorful and easy to read. The differences between data points are quickly seen based on the heights of the bars.

Example:

Researchers were interested in the ability of Colorado wildflowers to grow in different habitats. Although many of the species are suited to survive in various altitudes, soil types, and shade conditions, they wanted to see if there were any differences between growth in

a forest habitat compared to an open meadow habitat. Their data are shown in the following table.

Wildflower species	Maximum height in forest ($\bar{x} \pm 2$ SE)	Maximum height in meadow ($\bar{x} \pm 2$ SE)
Beeblossom	20 ± 6.1 cm	48 ± 8.8 cm
False hellebore	95 ± 10.8 cm	110 ± 9.2 cm
Fireweed	79 ± 9.4 cm	91 ± 14.6 cm
Silky lupine	32 ± 7.3 cm	39 ± 4.0 cm

For this dataset, the independent variable is the wildflower species and the dependent variable is the height in different habitats. Typically, bar graphs display discrete data on the *x*-axis. These are data that have a fixed value and can only be categorized in a certain way, such as the number of students in a

class. You can have 19 or 20 students, but you cannot have any in-between values, such as 19.5 students. In the table above, the different categories are species of wildflower. There are beeblossom and fireweed categories, but no beeblossom–fireweed hybrid category. The separate bars in a bar graph reflect the fact that the flowers are distinct categories.

When given discrete data in this format, especially with standard error calculations, bar graphs are a good choice. Having two differently colored bars, one for each habitat type, will make for easy reading and analysis of the graph.

The data in this graph also have error

bars. For more on error bars, see the explanations in Module 0 and Tutorial 1.

Bar graphs are versatile and can be presented in many ways. The above graph has single vertical bars, but some graphs have horizontal bars, multiple bars graphed adjacent to each other, or a combination of these features with two *y*-axes. To read the data, you need to study the key carefully. You may also see bar graphs with the different categories listed on the *y*-axis instead of the *x*-axis. Often this arrangement is to accommodate independent variables with longer names and is used to format the graph in a more visually appealing way.

Histogram

Histograms may appear very similar to

bar graphs because both include bars of differing heights. However, while bar graphs plot discrete data, histograms present continuous data, where decimal values are possible. Continuous data can take any value within a range. Temperature, time, and length are a few examples of data that can be continuous. Continuous data act as the independent variable and are plotted on the *x*-axis.

Example:

The researchers studying wildflowers were also interested in the elevations at which certain species grew. The table in the next column shows data collected for fireweed using a survey known as the nearest neighbor method. This involves choosing a random sampling point within a set area at these elevations and

measuring the distance between a plant and its nearest neighbor.

Elevation (m)	Average nearest neighbor distance (m)
0–610	0.29
610–1219	0.46
1219–1829	1.1
1829–2438	2.8
2438–3048	3.4

The table has given elevations in a range of several values. When data are presented in this way, it is likely that a histogram will be used. Elevation serves as the continuous data and should be plotted on the *x*-axis.

We can conclude that the fireweed flowers grew further from each other as elevation increased.

Your Turn

The following graphs are histograms taken from a study examining the infectiousness of the influenza virus in exhaled breath. The participants in this study were college-aged students, the majority of whom tested positive for influenza. The *x*-axis denotes the severity of the symptoms reported by the students. A higher number indicates more severe symptoms. Describe why these data are presented with a histogram instead of a bar graph.

Data from: https://www.pnas.org/content/115/5/1081

Solution

These data are suited for a histogram

because the scale on which the students graded the severity of their symptoms is continuous. The *x*-axes showing the severity values range from 0 to 15 and 0 to 9. However, many of the college students could have given scores that fell between whole numbers. This would not translate to a bar graph because bar graphs use discrete data, where categories are fixed.

Line Graphs

Line graphs are a simple way to track changes in data over time and are useful when plotting variables relative to each other. Each data point is connected with a line. The lines created can be straight, jagged, or curved, as long as they reflect the movement in the data.

Line graphs are useful when plotting two

variables relative to each other. In many cases, one variable is the independent variable and the other variable is the dependent variable. The independent variable is not affected by the other variable. For example, if you are collecting data at specific times, time is the independent variable because it elapses on its own, independent of whatever you are measuring. The independent variable is usually plotted on the *x*-axis.

The second variable is the dependent variable, which varies according to the independent variable. The dependent variable is the effect or result that is being observed or measured. This variable is considered dependent because it is expected to vary based on changes of the independent variable.

The dependent variable is usually plotted on the *y*-axis.

Example:

The following table shows the average monthly temperatures for the surface of the northern Atlantic Ocean in 2020.

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Average water temperature (°C)	19	18	18	19	19	21	23	25	25	24	22	21

Because the data track changes in temperature over one year, a line graph would best show these fluctuations. In this case, time is the independent variable and is plotted on the *x*-axis. Water temperature changes throughout the year, so it is the dependent variable and is plotted on the *y*-axis.

Temperature does not change very much, from a low of 19°C to a high of 25°C, so a scale increasing by increments of 1 will show the pattern well. We can include a range of temperatures from 16°C to 26°C on the *y*-axis because this range includes all the data points. Note that in this case, the *y*-axis does not begin at 0, but instead at 16, because there are no lower temperature values.

This graph tells us that the surface ocean temperature is colder in the winter months, but warms steadily through the spring and summer, before beginning to fall again.

Dual Y Graphs

There are also graphs that contain two *y*-axes on a common *x*-axis. These graphs,

which present the findings of multiple dependent variables, are known as dual Y graphs. They are used to show the changes in two variables over time. The variables usually have different units or different ranges in value. These differences are addressed by using one *y*-axis for each variable, with separate scales that reflect the variable plotted.

Example:

The following table shows data on atmospheric CO 2 CO_2 and CO 2 CO_2 emissions.

Year	1900	1920	1940	1960	1980	2000	2020
Atmospheric CO 2 CO_2 (ppm)	296	304	312	319	340	370	413
CO 2 CO_2 emissions (billions	2.1	3.7	5.0	9.6	19.0	25.0	36.7

of tons)

Data from https://www.climate.gov/news-features/understanding-climate/climate-change-atmospheric-carbon-dioxid

e

As you read this table from left to right, you can see that the value for each variable increases. However, values are increasing at different rates and magnitudes. The variables also have different units: one is in ppm, or parts per million, and the other is in billions of tons. For these reasons, a graph with two *y*-axes is useful. We can present the data at the same time and compare trends between the two, even with the differences in their scales.

This graph is read in the same way as any other graph with multiple variables. Be sure to pay attention to the color of the line for each variable, so that you read the data from the correct axis. The

relationship between these variables is quite clear: both atmospheric CO_2 and CO_2 emissions have increased dramatically over the past century.

Dual-Y graphs are not limited to line graphs. You may also see bar graphs, histograms, and other graph types with two *y*-axes. To read these graphs, start by differentiating the axis on which each variable is plotted and pay attention to the associated scales and units of each.

Log Scale

So far, we have looked at graphs that use a linear scale. Some graphs use a logarithmic scale on one or more axis. Logarithmic scales are used to display data that have large ranges in value. The examples we have dealt with have all had linear axes because the range

between data points has been relatively small. When the largest data are several hundred times larger than the smallest data, a log scale is used to simplify the graph. Smaller log bases are used to convey smaller ranges in the data. Most graphs use a logarithmic scale with log base 10.

Example:

A group of researchers is studying the population growth of a type of bacteria at different temperatures. They recorded population numbers every 5°C to 25°C. The results are given in the table.

Temperature (°C)	Number of bacteria
0	5
5	40
10	310
15	2500
20	15,000
25	85,000

There is an extremely large range between the smallest and largest population in this dataset. This is a sign that a logarithmic scale would be useful to present these data. In this example, the temperature is the independent variable and is plotted on the *x*-axis. Because the temperature data are linear and regular in range, we will use a logarithmic scale for the dependent variable on the *y*-axis, the number of bacteria.

The difference in presentation of these data with a linear *y*-axis compared to a logarithmic *y*-axis is significant. If we were to use a linear scale with increments of 10,000, the graph would look like the one at the top of the next column.

It looks like an exponential growth curve. It is difficult to read the first few data points because the scale is in increments of 10,000. The points at 0, 5, and even 10 could be read as the same number, even though they are different.

With a $\log 10$ $\log_{10}$ scale, the minimum value on the *y*-axis is 1 and the maximum value is 100,000, which is close to the maximum number of bacteria, 85,000. The *x*-axis remains unchanged. The graph now looks like this:

It is possible to read each data point more accurately, without having to refer

to the data table. Clearly, as the temperature increases, there is a constant and large increase in the number of bacteria as well. Note that logarithmic gridlines are different from linear gridlines. This changes how the *y*-axis data are read.

In this example, only one variable (number of bacteria) is plotted logarithmically, so it is considered a semilog ("half"-log) plot. When both variables are plotted logarithmically, it is called a log–log plot.

Pie Charts

Pie charts provide a fast way to visually gather what is happening in certain datasets. Pie charts are circles that represent 100% of the data, with different slices signifying the percentage

of a certain category out of the total. Each slice is given a different color or pattern, so the size of each category is easily seen. The largest slice of the pie represents the most abundant variable. The percentages should add up to 100.

Example:

A student studying forestry decided to count the number of tree species in a nearby plot of land. The following data were recorded.

Tree species	Pine	Elm	Oak	Walnut	Ash	Maple
Number of trees	38	15	24	9	13	17

This data are showing the abundance of trees. If we wanted to quickly see which tree species was the most abundant, a

pie chart would be useful. With one glance at the following graph, we can see immediately that pine trees make up the greatest percentage of this plot of land.

Your Turn

The following pie chart is based on global emissions data from 2010. Which three sectors contributed almost 75% of global greenhouse gas emissions? Estimate the percentages of the remaining three sectors.

Data from: https://www.epa.gov/ghgemissions/global-greenhouse-gas-emissions-data

Solution

The three sectors that make up nearly 75% of emissions are Electricity and heat production; Agriculture, forestry, and other land use; and Industry. These sectors represent approximately 25%, 25%, and 20% of the pie, respectively. The remaining three sectors are Transportation, Other energy, and Buildings. Their emissions are about 15%, 10%, and 5%, respectively.

Box and Whisker Graphs

A box and whisker graph is a good tool for visualizing the distribution of values in a dataset. These graphs are especially useful for comparing the distributions between several groups or datasets because they are compact. These graphs can have vertical or horizontal boxes, but each has the same components and can be read the same way. Box and

whisker plots are so named because of the appearance of the graph. They contain a bar resembling a box and two protruding lines called whiskers. The following figure identifies the major parts of a box and whisker plot, with important numbers listed in red.

The graph shows a small dataset comprised of these numbers: 35, 23, 18, 10, and 24. In numerical order, the dataset graphed is: 10, 18, 23, 24, 35. Out of these five data points, the median, or middle data point, is 23. This is shown on the graph by the horizontal line in the middle of the box. The median can also be called the 50th percentile. A percentile is a number where a certain percentage of values fall below that

number. So, half of the scores in the dataset are found below the median. The ends of each whisker represent the minimum and maximum values in the dataset, 10 and 35.

The line denoting the bottom of the box is the median of the lower half of the data. Twenty-five percent of the dataset falls below this number. The line denoting the top of the box is the median of the upper half of the data. Seventy-five percent of the dataset falls below this number. If we arrange the above dataset to exclude the median, it would look something like this: (10, 18), 23, (24, 25). We can find the median of the lower and upper halves of the data. Because there are an even number of values above and below the median, we have to average the two to calculate the

new medians:

$$\text{Lower box line} = (10 + 18) \div 2 = 14 \text{ Upp}$$

$$\text{Lower box line} = (10 + 18) \div 2 = 14$$

$$\text{Upper box line} = (24 + 25) \div 2 = 29.5$$

Looking back at the graph, we can see that the horizontal lines for the box have been drawn at 14 and 29.5, respectively.

Example:

The graph on the next page depicts an index of the distribution of rotifer species richness in different habitats. Rotifers are microscopic aquatic invertebrates. Identify the minimum, maximum, and median of rotifers in habitat B, and describe any patterns between the different habitats. Note that this graph contains an outlier, the empty circle above the rightmost box. Outliers are data points that are very far

from other points in the dataset.

Data from: https://www.researchgate.net/publication/284204454_Testing_the_habitat_selectivity_of_bdelloid_rotifers_in_a_restricted_area

Rotifer richness in habitat B is given by the second bar from the left. The minimum value is 2; the maximum value is 6; and the median is 3.

Habitat C has the largest minimum and largest maximum values of all habitats in the figure. If marked, it would also have the highest median value. We can conclude that it experiences the greatest species richness. Habitat A is the least species rich, having the lowest

minimum, maximum, and median values among the habitats examined. The other four habitats are very similar in species richness. Their medians and box values are nearly equal, with differences only in the range of minimum and maximum values.

Area Graphs

Area graphs are related to line graphs. The example at the top of the next column shows the number of COVID-19 cases per county in the San Francisco area. As you can see, the area underneath each line is shaded in. While line graphs measure the changes or differences between data points, area graphs focus on the different volume of data between two or more variables. They are primarily used to show trends in data over time.

In this case, we are seeing the number of COVID-19 cases on the *y*-axis over time plotted on the *x*-axis. Each county, such as Napa, Marin, and Sonoma, is graphed using a different color, indicated by the key at the top. Then the data for each county are stacked on top of each other. In this way, we can compare the number of COVID-19 cases in different counties by looking at the area of each color, while also keeping track of the total number of cases, which is indicated by the top of the purple (Santa Clara) line.

Data from: https://sfist.com/2020/03/26/covid-19-case-numbers-jump-in-san-francisco-and-alameda-counties-young-people/

Scatter Plot Graphs

Sometimes data are presented in a scatter plot. These graphs are used when individual data points are independent of each other and we want to assess if two variables are related. The following graph is a scatter plot showing how the pace of aging, as measured by various functional abilities, changes with a person's actual age.

Data from: https://www.pnas.org/content/112/30/E4104

We can use scatter plots to conclude if certain variables have a positive or negative correlation. Oftentimes, these correlations can easily be seen with a line of best fit. If both variables increase or decrease at the same time, they are said to have a positive correlation. If one

variable increases while the other decreases, they have a negative correlation. If the scatter plot has no discernable pattern, there is likely no relationship between the two variables.

Glossary

3′3′ end

The end of a DNA or RNA molecule that has a free 3′3′ hydroxyl group. By convention, the 3′3′ end is considered the end with the last nucleotide. (p. 80)

5′5′ end

The end of a DNA or RNA molecule that has a free 5′5′ phosphate group. By convention, the 5′5′ end is considered the end with the first nucleotide. (p. 80)

abiotic

Pertaining to nonliving things. (p. 4)

acid

A molecule that donates H + H^+ ions to a solution. When the concentration of hydrogen ions is greater than the concentration of hydroxide ions, the pH is acidic. (p. 49)

activation energy (EA) (E_A)

The energy input necessary to reach the transition state. (p. 199)

activator

A compound that increases the activity of an enzyme. (p. 205)

active site

The portion of an enzyme that binds substrate and converts it to product.

(p. 202)

active transport

The movement of substances across a cell membrane against a concentration gradient requiring an input of energy. (p. 148)

adaptation

The close fit between an organism and its environment. (p. 561)

adaptive radiation

A period of unusually rapid evolutionary diversification in which natural selection accelerates the rate of speciation within a group, with new species adapted for specific niches. (p. 674)

addition rule of probability

Rule which states that the probability of two mutually exclusive events happening is the sum of their individual probabilities. (p. 372)

adenine (A)
A purine base. (p. 79)

adenosine diphosphate (ADP)
A chemical relative of ATP that is composed of the base adenine, the five-carbon sugar ribose, and two phosphate groups. ADP contains less chemical energy than ATP does. (p. 187)

adenosine triphosphate (ATP)
The molecule that provides energy in a form that all cells can readily use to perform the work of the cell. (p. 96)

adhesion

The tendency of water molecules to stick to other polar or charged molecules. (p. 44)

agonist

A ligand that binds a receptor and leads to a response. (p. 305)

alleles

Different forms of a gene, corresponding to different DNA sequences. (p. 369)

allopatric

Describes populations that are geographically separated from each other. (p. 668)

allosteric site

A site other than the active site of an

enzyme. (p. 206)

alpha helix (α helix)

One of the two principal types of secondary structure found in proteins. (p. 70)

alternative hypothesis

A hypothesis that predicts that the independent variable in an experiment will have a real effect, and there will be a difference between the data collected from the control groups and experimental groups. (p. 11)

alternative splicing

The process by which exons are joined together and introns are removed during RNA processing. A

single gene can be spliced in different ways to yield different mRNAs and different protein products. (p. 465)

amino acid

The subunit of proteins. (p. 38)

amplification

The process in which a small number of signaling molecules can generate a very large response. (p. 293)

anabolism

The set of chemical reactions that build molecules from smaller units utilizing an input of energy, usually in the form of ATP. Anabolic reactions result in net energy storage within cells and the organism. (p. 193)

anaphase

The phase of mitosis in which sister chromatids separate. (p. 328)

antagonist

A ligand that binds a receptor and inhibits a response. (p. 305)

anticodon

The sequence of three nucleotides in a tRNA molecule that base pairs with the corresponding codon in an mRNA molecule. (p. 471)

antiparallel

Oriented in opposite directions, like the two strands in a DNA molecule. (p. 82)

apoptosis

The genetically programmed death of a cell. (p. 340)

aquaporin

A channel protein that allows water to cross the cell membrane more readily than by diffusing through the lipid bilayer. (p. 147)

archaea

One of the three domains of life, consisting of unicellular organisms that differ from bacteria in many aspects of their cell and molecular biology. (p. 98)

artificial selection

A form of directional selection similar to natural selection, but with selection done intentionally by humans, usually with a specific goal in mind, such as increased milk yield in cattle. (p. 580)

asexual reproduction

The reproduction of organisms in which an offspring inherits its DNA from a single parent. (p. 323)

atom

The basic unit of matter. (p. 26)

atomic mass

The total mass of an atom; consists of the number of protons and neutrons in the atom. (p. 30)

atomic number

The number of protons in an element. (p. 30)

ATP synthase

An enzyme that couples the movement of protons through the enzyme with the synthesis of ATP. (p.

225)

autosome

A chromosome that is not a sex chromosome. (p. 352)

autotroph

Organism that obtains energy by photosynthesis or chemosynthesis. Also known as a producer. (p. 741)

bacteria

One of the three domains of life, consisting of unicellular organisms that differ from archaea in many aspects of their cell and molecular biology. (p. 98)

base

A molecule that accepts H + H^+ ions and removes them from solution.

When the concentration of hydrogen ions is less than the concentration of hydroxide ions, the solution is basic or alkaline. (p. 49)

beta sheet (β sheet)
One of the two principal types of secondary structure found in proteins. (p. 71)

biodiversity
Biological diversity; the total number of species, or, more broadly, the diversity of genetic sequences, cell types, metabolism, life history, phylogenetic groups, communities, and ecosystems. (p. 562)

biological species concept (BSC)
As described by Ernst Mayr, the

concept that “species are groups of actually or potentially interbreeding populations that are reproductively isolated from other such groups.” The BSC is the most widely used and accepted definition of a species, but cannot be applied to asexual or extinct organisms. (p. 663)

biological system

A system made of both biological and physical entities that interact and, as a result, show complex properties. (p. 4)

biologist

A scientist who studies biology. (p. 1)

biology

The science of how life works. (p. 1)

biotic

Pertaining to life and living organisms. (p. 4)

bottleneck

An extreme, usually temporary, reduction in population size that may result in marked loss of genetic diversity and, in the process, genetic drift. (p. 603)

Calvin cycle

The process in which carbon dioxide is reduced to synthesize carbohydrates, with ATP and NADPH as the energy sources. (p. 217)

cancer

A condition of unregulated cell division, often resulting in the

development of tumors and disease. (p. 336)

carbohydrate

A type of organic molecule. (p. 38)

carbon-14 (14C) (^{14}C)

A radioactive isotope of carbon frequently used in radiometric dating. (p. 624)

carrier protein

A transport protein that facilitates movement of molecules across a cell membrane. (p. 147)

carrying capacity (*K*)

A limit on how many individuals can be supported in a given environment. (p. 760)

catabolism

The set of chemical reactions that break down molecules into smaller units and, in the process, produce ATP to meet the energy needs of the cell. (p. 193)

catalyst

A compound that increases the rate of a chemical reaction, but emerges from the process unaltered. (p. 197)

cell

The simplest self-reproducing entity that can exist as an independent unit of life. (p. 1)

cell cycle

The collective name for the steps that make up the life cycle of a eukaryotic

cell, including DNA replication and mitotic cell division. (p. 324)

cell division

The process by which a parent cell gives rise to two daughter cells. (p. 322)

cell membrane

The membrane that surrounds the cytoplasm of the cell, separating the inside of the cell from the outside of the cell; also known as **plasma membrane**. (p. 58)

cell theory

The set of ideas that places the cell at the center of life. It states that the cell is the fundamental unit of life, that organisms are made up of one or

more cells, and that cells arise from preexisting cells. (p. 93)

cellular respiration

A series of chemical reactions in which organic molecules are oxidized to carbon dioxide, converting the energy stored in organic molecules to ATP. (p. 110)

central dogma

The idea that information in a cell usually flows from DNA to RNA to protein. (p. 84)

centromere

A region of DNA where sister chromatids can be held together, it is also the place where the mitotic spindle attaches to drive chromosome

movement during mitosis. (p. 325)

centrosome

A compact structure that is the microtubule organizing center for animal cells. (p. 326)

channel protein

A transport protein with a passage that allows the movement of molecules through it. (p. 147)

character

An anatomical, physiological, or molecular feature of an organism that varies among taxa. (p. 651)

checkpoint

A point of transition between one phase of the cell cycle and the next phase of the cell cycle. (p. 338)

chemical bond

A form of attraction between atoms that holds them together. (p. 33)

chemical energy

A form of potential energy held in the chemical bonds between pairs of atoms in a molecule. (p. 185)

chemical reaction

A process by which molecules are transformed into different molecules. (p. 35)

chemiosmosis

The movement of ions, such as hydrogen ions (protons), from a region of high concentration to a region of low concentration across a selectively permeable membrane,

similar to the movement of water by osmosis. In mitochondria and chloroplasts, chemiosmosis powers the synthesis of ATP by ATPase. (p. 251)

chemosynthesis

The biochemical process in which the energy of chemical compounds is used to build sugars. (p. 740)

Chi-square ($\chi 2$)(χ^2) test

A statistical test that determines whether the number of observed events in different categories differs from an expected number of events. (p. 374)

chlorophyll

The major photosynthetic pigment

contained in the photosynthetic membranes; it plays a key role in the cell's ability to capture energy from sunlight. (p. 112)

chloroplast

An organelle in photosynthetic eukaryotes that converts energy of sunlight into chemical energy by synthesizing simple sugars. (p. 111)

chromatin

Inside the eukaryotic nucleus, chromatin refers to the assemblage of DNA, RNA, and protein that fills the nucleus. (p. 326)

chromosome

A cellular structure containing the genetic material in cells, consisting of

a single DNA molecule with associated proteins. (p. 324)

cladogram

A type of phylogenetic tree that shows clades, or monophyletic groups. (p. 650)

codon

A group of three adjacent nucleotides in mRNA that specifies an amino acid in a protein or that terminates protein synthesis. (p. 471)

cohesion

Tendency of water molecules to stick to one another due to hydrogen bonding with one another. (p. 44)

commensalism

An interaction in which one species

receives a benefit while the other species is neither harmed nor helped. (p. 787)

competition

An interaction between species that require the same limited resource. (p. 786)

complementary

Describes the relationship of purine and pyrimidine bases, in which the base A pairs only with T, and G pairs only with C. (p. 83)

complex carbohydrate

A long, branched chain of monosaccharides. (p. 57)

concentration gradient

A difference in concentration of a

substance, with regions of higher and lower concentration. (p. 146)

conjugation

The direct cell-to-cell transfer of DNA, usually a plasmid; a form of horizontal gene transfer. (p. 520)

contractile vacuole

An organelle in some protists that actively takes up and expels water that enters the cell by osmosis. (p. 159)

control group

A group that is not exposed to the independent variable in an experiment and therefore is not expected to show a change; also known as a **negative control**, or

control for short. (p. 7)

controlled experiment

An experiment in which there are at least two groups to be tested and the conditions and setup are almost identical for the groups except that one group (the test or experimental group) deliberately has a variable introduced, whereas the other (control) group does not. (p. 7)

convergent evolution

The independent evolution of similar traits in different species as a result of similar environments or selective pressures. (p. 577)

cooperative behavior

A behavior that helps a member of

the same species improve another individual's fitness. (p. 731)

covalent bond

A bond in which two atoms share a pair of electrons. (p. 33)

crossing over

A process in prophase I in meiosis when each chromatid can break at the chiasma and then connect to a non-sister chromatid. Also known as **recombination.** (p. 354)

cyclic adenosine monophosphate (cAMP)

Derived from ATP and serves as an intracellular second messenger in many signal transduction pathways. (p. 293)

cyclin-dependent kinase (CDK)
An enzyme that is activated by binding to the appropriate cyclin partner, gaining the ability to transfer a phosphate group to a target protein. (p. 337)

cyclins
A family of several different proteins that are produced in different amounts during different phases of the cell cycle so that they can bind to and regulate cyclin-dependent kinases, thus cueing the progression of the cell cycle. (p. 337)

cytokinesis
The stage of M phase in which the cytosol, organelles, and duplicated nuclei from one eukaryotic cell divide

into two daughter cells. (p. 324)

cytoplasm

The region of the cell outside of the nucleus. (p. 98)

cytosine (C)

A pyrimidine base. (p. 79)

cytoskeleton

An internal protein scaffold that helps cells to maintain their shape. (p. 112)

cytosol

The region of the cell inside the cell membrane but outside the organelles; the jelly-like internal environment that surrounds the organelles. (p. 101)

dehydration synthesis reaction

A reaction in which a water molecule

is released by the two reacting molecules as a new covalent bond is formed between them. Dehydration synthesis reactions build large molecules from smaller subunits. Also called dehydration reaction. (p. 50)

denature

Unfold, as a protein. A protein that unfolds loses its function, as the shape of a protein is closely connected to its function. (p. 204)

density-dependent factor

Factors that limit population growth as its size increases. (p. 766)

density-independent factor

Factors that reduce density regardless

of a population's size. (p. 765)

deoxyribonucleic acid (DNA)
The carrier molecule of genetic information for all organisms. (p. 4)

deoxyribose
The pentose sugar component of DNA. (p. 56)

dependent variable
The variable that is being tested, observed, or measured, and that may change due to the independent variable. (p. 8)

derived character
A character or trait that is newly evolved; an evolutionary innovation. (p. 652)

differentiation

The process by which cells become progressively more specialized as a result of gene regulation. (p. 499)

diffusion

The net movement of molecules from areas of higher to lower concentration of the molecules due to random motion. (p. 124)

dihybrid cross

A mating in which hybrid individuals differ in two traits that are coded by two different genes. (p. 378)

diploid

A cell with two sets of chromosomes (denoted as $2n$). (p. 351)

directionality

An asymmetry such that one end of a structure differs from the other. Also known as **polarity**. (p. 80)

disaccharide

Two simple sugars joined by a covalent bond; an example is sucrose. (p. 57)

distribution

A description which typically takes the form of a list or graph of all of the possible values of a particular variable and their frequencies. The distribution describes the spread of the data and how often each value occurs. (p. 21)

divergent evolution

The process by which two groups of

organisms become genetically and physically different from each other over time. (p. 668)

DNA editing

Techniques used to “rewrite” a nucleotide sequence so that specific mutations can be introduced into genes to better understand their function, or to correct mutant versions of genes to restore normal function. (p. 536)

DNA ligase

An enzyme that joins two DNA fragments together. (p. 454)

DNA polymerase

An enzyme that is a critical component of a large protein complex

that carries out DNA replication. (p. 451)

DNA replication

The process of duplicating a DNA molecule, during which the parental strands separate and new partner strands are made. (p. 339)

domain

One of the three largest limbs of the tree of life: Eukarya, Bacteria, or Archaea. (p. 98)

dominant

Describes an allele or trait that is expressed in heterozygotes. Only one dominant allele is needed to express the phenotype. (p. 369)

double bond

A covalent bond in which two atoms share two pairs of electrons. (p. 33)

double helix

The structure formed by two strands of complementary nucleotides that coil around each other. (p. 81)

Down syndrome

A condition in humans caused by an extra chromosome 21. (p. 425)

ectotherm

An animal that obtains most of its heat to warm its body from the environment. (p. 737)

electron

An atomic particle that moves around the nucleus and carries a negative charge. (p. 30)

electron shell

See **energy level.** (p. 31)

electronegativity

Difference in the ability of atoms to attract electrons. (p. 34)

element

A chemical that cannot be split into other chemicals. (p. 30)

emerging disease

An infectious disease that has appeared recently and/or spread rapidly. (p. 547)

endergonic

Describes reactions with a positive ΔG that are not spontaneous and so require an input of energy. (p. 191)

endocytosis

The process in which a vesicle buds off from the cell membrane, bringing material from outside the cell into that vesicle, which can then fuse with other membranes. (p. 151)

endomembrane system

A cellular system present in eukaryotic cells that includes the nuclear envelope, the endoplasmic reticulum, the Golgi apparatus, lysosomes, the cell membrane, and the vesicles that move between them. (p. 106)

endoplasmic reticulum (ER)

An organelle composed of a network of membranes that is involved in the synthesis of proteins and lipids. (p.

endosymbiosis
A symbiosis in which one partner lives within the other. (p. 173)

endotherm
An animal that produces most of its heat as a by-product of metabolic reactions to maintain a warm and steady body temperature. (p. 736)

energetic coupling
The driving of a non-spontaneous reaction by a spontaneous reaction. (p. 192)

energetics
The science of the properties of energy and how energy is distributed in biological, chemical, and physical

processes. (p. 4)

energy

The ability to do work. (p. 4)

energy level

An area in space where electrons circle around the nucleus. Also called an **electron shell**. (p. 31)

entropy

The amount of disorder, or the number of possible positions and motions of molecules, in a system. (p. 188)

enzyme

A protein that functions as a catalyst to accelerate the rate of a chemical reaction. (p. 107)

epigenetic

Describes effects on gene expression due to differences in DNA packaging and chromosome organization, such as modifications in histones or chromatin structure. (p. 493)

eukarya

One of the three domains of life, in which cells have a nucleus. (p. 101)

eukaryotic

Describes a cell that has a nucleus; used to refer collectively to animals, plants, fungi, and protists. (p. 98)

evolution

A change in the genetic makeup of a population over time. (p. 2)

evolutionarily conserved

Characteristics that persist relatively unchanged through diversification of a group of organisms and therefore remain similar in related species. (p. 503)

exergonic

Describes reactions with a negative ΔG that proceed spontaneously and release energy. (p. 191)

exocytosis

The process in which a vesicle fuses with the cell membrane and empties its contents into the extracellular space or delivers proteins to the cell membrane. (p. 150)

exon

A sequence that is left intact in mRNA

after RNA splicing, and is therefore expressed in the protein. (p. 465)

experimental group

See **Test group**. (p. 7)

exponential growth model

A model of a population that continues to grow rapidly over time in an exponential manner. (p. 758)

extinction

The loss of a group of organisms, typically a species. (p. 682)

facilitated diffusion

Diffusion across a cell membrane through a transmembrane protein, such as a channel or carrier. (p. 147)

fatty acid

A long chain of carbons attached to a carboxyl group; three fatty acid chains attached to glycerol form a triacylglycerol, a lipid used for energy storage. (p. 58)

fermentation

A variety of metabolic pathways that produce ATP from the partial oxidation of organic molecules without oxidative phosphorylation or an electron acceptor, such as oxygen. (p. 254)

first law of thermodynamics

The law of conservation of energy, which states that energy can be neither created nor destroyed; it can only be transformed from one form into another. (p. 188)

fitness

A measure of the ability of an individual to survive and reproduce in a particular environment; the extent to which the individual's genotype is represented in the next generation. (p. 262)

fluid mosaic model

A model proposing that the lipid bilayer is a dynamic structure that allows molecules to move laterally within the membrane and is a mosaic, or mixture, of several components, including lipids, proteins, and carbohydrates. (p. 141)

fossil

The remains of a once-living organism. (p. 620)

founder effect

A type of genetic drift that occurs when only a few individuals establish a new population. (p. 603)

functional group

A group of one or more atoms that has a particular chemical property on its own, regardless of what it is attached to. (p. 55)

G protein-coupled receptor

A receptor protein in cell membranes that is associated with a G protein that in turn alters activity of adenylyl cyclase and other generators of second messengers in responding cells. (p. 293)

G0G_0 phase

The phase in the cell cycle in which cells pause between M phase and S phase; it may last for periods ranging from days to more than a year. (p. 326)

G1 G_1 phase

The phase during interphase in which the cell synthesizes regulatory proteins controlling the eukaryotic cell cycle. (p. 325)

G2 G_2 phase

The phase during interphase after DNA has been replicated, characterized by increases in cell size and protein contents. (p. 325)

gamete

A reproductive haploid cell; gametes

fuse to form a diploid zygote. In many species, there are two types of gametes: eggs in females, sperm in males. (p. 356)

gel electrophoresis

A technique that is used to separate DNA and RNA based on size, and proteins based on size and charge, using an electric current passed through a jelly-like substance. (p. 529)

gene

The unit of heredity affecting one or more traits of an organism; the DNA sequence that corresponds to a specific protein or noncoding RNA. (p. 1)

gene expression

The production of a functional gene product, such as a protein; the "turning on" of a gene. (p. 436)

gene flow

The movement of alleles from one population to another through interbreeding between members of each population. (p. 605)

gene regulation

The various ways in which cells control gene expression. (p. 440)

genetic code

The correspondence between codons and amino acids, in which 20 amino acids are specified by 64 codons. (p. 473)

genetic drift

A random change in the frequency of an allele due to chance. (p. 603)

genetic variation

The range of different genotypes found among individuals. (p. 351)

genetically modified organism (GMO)

An organism that has been genetically engineered, such as modified viruses and bacteria, laboratory organisms, agricultural crops, and domestic animals; also called a transgenic organism. (p. 535)

genome

All of the genetic information that an individual, or a species, contains. (p. 1)

genotype
The set of genes that an organism carries. (p. 350)

Gibbs free energy (*G*)
The amount of energy available to do work. (p. 191)

glycerol
A 3-carbon molecule with hydroxyl groups attached to each carbon; a component of triacylglycerol. (p. 58)

glycolipid
A carbohydrate that is covalently linked to a lipid. (p. 141)

glycolysis
The breakdown of glucose to pyruvate; the first stage of cellular respiration. (p. 237)

glycoprotein

A carbohydrate that is covalently linked to a protein. (p. 141)

Golgi apparatus

An organelle that modifies proteins and lipids produced by the endoplasmic reticulum and acts as a sorting station as they move to their final destinations. (p. 108)

gradualism

The idea that species change slowly over time. (p. 676)

grana (singular, granum)

Interlinked stacks of thylakoids in chloroplasts. (p. 111)

GTP cap

The modification of the 5′5′ end of the

primary transcript by the addition of a special nucleotide attached in an unusual chemical linkage; also called a 5′5′ cap. (p. 464)

guanine (G)

A purine base. (p. 79)

half-life

The time it takes for an amount of a substance to reach half its original value. Radioactive half-life is the time it takes for half of the atoms in a given sample of a substance to decay. (p. 625)

haploid

A cell with one set of chromosomes (denoted as $1n$). (p. 352)

Hardy–Weinberg equilibrium

A state in which allele and genotype frequencies do not change over time, implying the absence of evolutionary forces. It also specifies a mathematical relationship between allele frequencies and genotype frequencies. (p. 607)

helicase

An enzyme that separates the two DNA strands at the replication fork so that each strand can be copied during DNA replication. (p. 451)

heterotroph

An organism that obtains energy by eating other organisms. Also known as a consumer. (p. 741)

heterozygous

A condition in which an individual possesses two different alleles for a given gene. (p. 317)

homeostasis

The active regulation and maintenance of a stable internal physiological state in the face of a changing external environment. (p. 95)

homologous chromosomes

Two chromosomes that are similar in size and shape, and that carry the same genes. (p. 352)

homozygous

A condition in which an individual possesses two identical alleles for a given gene. (p. 370)

horizontal gene transfer
The transfer of genetic material between organisms that are not parent and offspring. (p. 520)

hormone
A signaling molecule that is transported in the circulatory system by endocrine signaling. (p. 279)

hydrogen bond
An interaction between a hydrogen atom with a slight positive charge and an electronegative atom of another molecule. In the case of water, hydrogen bonds form between the hydrogen atom of one water molecule and oxygen atom of another water molecule. (p. 44)

hydrolysis reaction
A reaction that adds water across a covalent bond and breaks the covalent bond. Hydrolysis reactions break down larger molecules into smaller, simpler molecules. (p. 51)

hydrophilic
"Water loving"; describes polar molecules that readily dissolve in water. (p. 38)

hydrophobic
"Water fearing"; describes nonpolar molecules that do not dissolve well in water. (p. 38)

hypertonic
Describes a solution having a higher solute concentration (lower water

potential) than another solution. (p. 159)

hypothesis

A tentative explanation for one or more observations that make predictions that can be tested by experimentation or additional observations. (p. 6)

hypotonic

Describes a solution having a lower solute concentration (higher water potential) than another solution. (p. 159)

independent variable

The variable that is manipulated or added to an experimental group to test a hypothesis. (p. 8)

inhibitor

A compound that decreases the activity of an enzyme. (p. 205)

innate behavior

A behavior that is performed without any previous experience. (p. 728)

integral membrane protein

A protein that is permanently associated with the cell membrane and cannot be separated from the membrane experimentally without destroying the membrane itself. (p. 139)

interphase

One of two major phases of the eukaryotic cell cycle, in which the cell copies its DNA and synthesizes

proteins necessary for mitosis. (p. 324)

intron

An intervening sequence that is removed from the primary transcript during RNA splicing. (p. 465)

invasive species

Non-native species that become established in new ecosystems. (p. 628)

ion

An electrically charged atom. (p. 31)

ionic bond

A bond in which two ions with opposite electrical charges associate with each other. (p. 34)

isotonic

Describes a solution having the same solute concentration (same water potential) as another solution. (p. 159)

isotope

One of two or more forms of the same element with different numbers of neutrons. (p. 30)

karyotype

A visual display of the pairs of chromosomes. (p. 352)

keystone species

Pivotal populations that affect other members of the community in ways that are disproportionate to their abundance or biomass. (p. 788)

kinase

An enzyme that catalyzes the transfer of a phosphate group from ATP to another molecule. (p. 293)

kinetic energy

The energy of motion. (p. 185)

kinetochore

The protein complex on a chromatid where the mitotic spindle attaches. (p. 328)

Krebs cycle

The third stage of cellular respiration, in which acetyl-CoA is broken down and carbon dioxide is released; also called the citric acid cycle. (p. 237)

lagging strand

A daughter strand that has its 5′5′ end pointed toward the replication fork,

so as the parental double helix unwinds, a new DNA piece is initiated at intervals, and each new piece is elongated at its 3′3′ end until it reaches the piece in front of it. (p. 453)

law of independent assortment
The principle that segregation of one set of alleles for one gene is independent of the segregation of a second set of alleles for a different gene. (p. 378)

law of segregation
The principle that half of the gametes receive one allele of a gene and half receive the other allele. This principle is explained by meiosis, in which the maternal and paternal homologous

chromosomes separate during anaphase I. (p. 370)

leading strand

A daughter strand that has its 3′3′ end pointed toward the replication fork, so as the parental double helix unwinds, this daughter strand can be synthesized as one long, continuous polymer. (p. 453)

learned behavior

A behavior in which the individual's experience in its environment plays a large role. (p. 728)

ligand

A signaling molecule with a molecular shape and distribution of charge that allows it to match up with

and bind to a complementary receptor protein. (p. 277)

ligand-gated channel

Receptor proteins in cell membranes that alter membrane permeability to ions after binding to an extracellular hydrophilic signaling molecule. (p. 299)

light reactions

The series of chemical reactions during photosynthesis in which the energy of sunlight is used to synthesize NADPH and ATP. (p. 217)

linked genes

Genes that are physically located near each other on the same chromosome. (p. 398)

lipid

A type of organic molecule that is hydrophobic; lipids make up the barrier between the cell and its environment, store energy, and act as signaling molecules. (p. 38)

lipid bilayer

A two-layered structure of the cell membrane made up of lipids with hydrophilic heads pointing outward toward the aqueous environment and hydrophobic tails oriented inward away from water. (p. 133)

logistic growth model

A growth model that describes population growth when there is a density-dependent carrying capacity. (p. 768)

lysosome

A vesicle derived from the Golgi apparatus that contains enzymes that break down macromolecules such as proteins, nucleic acids, lipids, and carbohydrates. (p. 109)

M phase

One of two major phases of the eukaryotic cell cycle, consisting of mitosis and cytokinesis. (p. 324)

maternal inheritance

A type of inheritance in which the organelles in the offspring cells derive from those in the mother. (p. 401)

matter

Material that makes physical objects.

(p. 26)

maximum per capita growth rate (rmax) (r_{max})

The maximum growth rate possible for a population living without any constraints. (p. 758)

mean

A measure of the average of a set of numbers. The mean is determined by adding all the values and dividing by the number of values. (p. 20)

median

The middle number in a set of numbers when ordered from lowest to highest. (p. 20)

meiosis

A form of cell division in which a

parental cell divides in two stages to produce four daughter cells. (p. 352)

meiosis I

The first step in meiosis in which homologous chromosomes are separated from each other. (p. 353)

meiosis II

The second step in meiosis in which sister chromatids are separated from each other. (p. 353)

messenger RNA (mRNA)

The RNA molecule that combines with a ribosome to direct protein synthesis; it carries the genetic "message" from the DNA to the ribosome. (p. 463)

metabolic pathway

A series of chemical reactions that build or break down molecules in cells. (p. 186)

metabolic rate

The number of calories burned by an organism over time while at rest. (p. 738)

metabolism

The chemical reactions occurring within cells that convert one molecule into another and transfer energy in living organisms. (p. 96)

metaphase

The phase of mitosis in which the chromosomes align in the middle of the dividing cell. (p. 328)

migration

The movement of individuals from one population to another or to areas with no prior population. (p. 604)

mitochondria (singular, mitochondrium)

Specialized organelles that are the site of cellular respiration in eukaryotic cells, oxidizing chemical compounds such as sugars to carbon dioxide and transferring their chemical energy to ATP. (p. 110)

mitochondrial matrix

The space enclosed by the inner membrane of the mitochondria. (p. 110)

mitosis

The stage of M phase that produces

two identical nuclei during the eukaryotic cell cycle. (p. 324)

mitotic spindle

A structure in the cytosol made up predominantly of microtubules that pull the chromosomes into separate daughter cells. (p. 326)

mode

The most common number in a set of numbers. (p. 21)

molarity

The amount of a solute in a volume of solution, expressed as moles of a solute per liter of solution. Also called molar concentration. (p. 156)

molecular clock

The observation that the extent of

genetic divergence between two groups is a reflection of the time since the groups shared a common ancestor. (p. 618)

molecule

A chemical formed of two or more atoms. (p. 26)

monohybrid cross

A cross between two individuals that are hybrids for a single gene, meaning they possess two different alleles. (p. 369)

monomer

A single molecule that can bond chemically with similar molecules in a polymer. (p. 37)

morphological homology

An anatomical structure that is similar in two groups of organisms because it was present in the common ancestor of the two groups and retained over evolutionary time. (p. 616)

multiplication rule of probability
A rule which states that the probability of two independent events both happening is the product of their individual probabilities. (p. 372)

mutagen
An agent that increases the probability of mutation. (p. 520)

mutation
Any heritable change in the genetic material, usually a change in the

nucleotide sequence of a gene. (p. 305)

mutualism

A special type of symbiosis in which both species benefit in regard to their growth or reproduction. (p. 787)

natural selection

A mechanism of evolution that occurs when there is genetic variation in a population of organisms and the variants best suited for survival and reproduction in a particular environment contribute disproportionately to future generations. Of all the evolutionary mechanisms, only natural selection leads to adaptations. (p. 3)

negative control

See **control.** (p. 8)

negative feedback

A process in which the response or output of a system opposes the initial stimulus, resulting in steady conditions, or homeostasis. (p. 285)

negative regulatory molecule

A molecule, such as a repressor, that binds to the DNA at a site near the gene to prevent transcription. (p. 486)

neutron

An atomic particle of the nucleus that carries no charge. (p. 30)

niche

A complete description of the role a species plays in its environment, and

of its requirements, both abiotic and biotic. (p. 665)

nicotinamide adenine dinucleotide phosphate (NADPH)
An electron carrier in many biochemical reactions; the reducing agent used in the Calvin cycle during photosynthesis. (p. 214)

nitrogenous base
A nitrogen-containing compound that makes up part of a nucleotide. (p. 78)

node
In phylogenetic trees, the point where a branch splits, representing the common ancestor from which the descendant species diverged. (p. 564)

non-sister chromatids

Chromatids that are not connected by a centromere. (p. 354)

nondisjunction

The failure of a chromosome to separate during anaphase of cell division. (p. 423)

nonpolar covalent bond

A bond that results when electrons are shared equally, or nearly equally, between two atoms. (p. 34)

nonrandom mating

Mate selection that is not random, but instead is based on genotype or relatedness. (p. 606)

nontemplate strand

The strand of DNA that is not used as a template, or model, for RNA

synthesis during transcription. The nontemplate strand is the reverse complement of the template strand. The nontemplate strand is also called the coding, sense, and plus strand. (p. 460)

normal distribution

A symmetric distribution or bell curve in which most of the values cluster in the middle and fewer values are found at the extremes. In a normal distribution, approximately 68% of the values lie within one standard deviation on either side of the mean, and 95% of the values lie within two standard deviations on either side of the mean. (p. 21)

nuclear envelope

The two membranes, inner and outer, that define the boundary of the nucleus. (p. 106)

nucleic acid

A type of organic molecule that encodes and transmits genetic information. (p. 38)

nucleotide

A subunit of nucleic acids, consisting of a 5-carbon sugar, a nitrogen-containing base, and one or more phosphate groups. (p. 38)

nucleus

The dense, central part of an atom. (p. 30)

nucleus (of a cell)

The compartment of the cell that

houses the DNA in chromosomes. (p. 98)

null hypothesis

A hypothesis that predicts that the independent variable in a controlled experiment will not have a real effect, and any difference between the data collected from the control groups and experimental groups is due to chance. (p. 11)

observation

The act of viewing the world around us. (p. 5)

operon

A group of functionally related genes located in tandem along DNA and transcribed as a single unit from one

promoter in prokaryotes. (p. 478)

organelle

Any one of several compartments in a eukaryotic cell that divides the cell contents into smaller spaces specialized for different functions. (p. 101)

organic molecule

A molecule made of carbon. (p. 26)

organism

A living individual entity that displays the properties of life. (p. 1)

osmoregulation

The regulation of water and solute levels to control osmotic pressure. (p. 163)

osmosis

The net movement of a solvent, such as water, across a selectively permeable membrane toward the side of higher solute concentration. (p. 156)

osmotic pressure

The pressure needed to prevent water from moving from one solution into another by osmosis. (p. 157)

outgroup

A group of organisms that has an older common ancestor than the common ancestor of the group of interest, and therefore serves as a reference for evolutionary relationships within the group of interest. (p. 654)

oxidation

A chemical reaction in which a molecule loses electrons and energy. (p. 214)

oxidative phosphorylation

A set of chemical reactions that occurs by passing electrons along an electron transport chain to a final electron acceptor, oxygen, pumping protons across a membrane, and using the proton electrochemical gradient to drive the synthesis of ATP. (p. 236)

parasitism

An interaction in which one species lives in or on another organism, known as the host. (p. 785)

passive transport

The movement of molecules across a cell membrane by diffusion. (p. 146)

paternal inheritance

A type of inheritance in which the organelles in the offspring cells derive from those in the father. (p. 401)

pedigree

A visual mapping of phenotypes using ancestral relationships. (p. 380)

peptide

A molecule made by joining amino acids together by peptide bonds. Peptides may range from as few as two to many hundreds of amino acids linked together. (p. 69)

peptide bond
The bond between the carboxyl end of an amino acid and the amino end of another amino acid that creates a peptide. (p. 69)

per capita growth rate (*r*)
The rate of population change divided by the size of the population. (p. 756)

periodic table of the elements
A table in which the elements are indicated by their chemical symbols and arranged in order of increasing atomic number. (p. 31)

peripheral membrane protein
A protein that is temporarily associated with the lipid bilayer or with integral membrane proteins

through weak noncovalent interactions. (p. 139)

pH scale

A measure of the acidity of a solution. The pH scale ranges from 0 to 14 and is calculated by the negative logarithm of the hydrogen ion concentration. (p. 49)

phenotype

The set of traits that an organism expresses, such as hair color or eye color. (p. 350)

phenotypic plasticity

The ability of a single genotype to produce different phenotypes in different environments. (p. 406)

phospholipid

A type of lipid and a major component of the cell membrane. (p. 61)

photophosphorylation
The process by which energy from sunlight drives the movement of electrons along an electron transport chain, which leads to the synthesis of ATP. (p. 226)

photosynthesis
The biochemical process in which the energy of sunlight is used to synthesize carbohydrates from carbon dioxide and water. (p. 111)

photosynthetic electron transport chain
A series of redox reactions in which

light energy absorbed by chlorophyll is used to power the movement of electrons; in oxygenic photosynthesis, the electrons ultimately come from water, and the terminal electron acceptor is NADP+ $NADP^+$. (p. 217)

photosystem

A protein–pigment complex that absorbs light energy to drive redox reactions and thereby sets the photosynthetic electron transport chain in motion. (p. 224)

phylogenetic tree

A tree-like diagram representing a hypothesis about the evolutionary relationships among populations or species. (p. 563)

phylogeny
The history of descent with modification and the accumulation of change over time. (p. 645)

plasma membrane
See **cell membrane.**

plasmid
In bacteria, a small circular molecule of DNA carrying a small number of genes that replicates independently of the DNA in the bacterium's circular chromosome. (p. 442)

plasmodesmata
Connections between two adjacent plant cells that permit molecules and other substances to pass directly from the cytoplasm of one cell to the

cytoplasm of another. (p. 282)

polar (molecule)

A molecule that has regions of positive and negative charge. (p. 43)

polar covalent bond

A bond that results when electrons are shared unequally between two atoms. (p. 34)

polarity

See **directionality**. (p. 80)

poly(A) tail

The adenine (A) nucleotides added to the 3′3′ end of the primary transcript. (p. 465)

polymer

A large molecule composed of many

smaller subunits. (p. 37)

polymerase chain reaction (PCR)
A selective and highly sensitive method for making copies of a piece of DNA, which allows a targeted region of a DNA molecule to be replicated into as many copies as desired. (p. 526)

polypeptide
A polymer of amino acids connected by peptide bonds. (p. 69)

polyploidy
The condition of having more than two complete sets of chromosomes in the genome. (p. 517)

polysaccharide
A polymer of simple sugars.

Polysaccharides provide long-term energy storage or structural support. (p. 57)

population

All the individuals of a given species that live and reproduce in a particular place; one of several interbreeding groups of organisms of the same species living in the same geographical area. (p. 276)

positive control

A sample or group that receives a treatment or variable with a known effect in a controlled experiment and therefore is expected to show a predictable change. (p. 8)

positive feedback

A pattern of response in which the output or signal of a communication system increases the activity in the same system that produced the signal. (p. 285)

positive regulatory molecule
A molecule, such as an activator, that binds to DNA at a site near a gene so that transcription can take place. (p. 486)

postzygotic
Describes factors that cause the failure of a fertilized egg to develop into a fertile individual. (p. 666)

potential energy
Stored energy related to an object's structure or position. (p. 185)

predation
An interaction that involves one species killing and consuming another. (p. 784)

pressure potential
The effect of pressure in the movement of water. (p. 160)

prezygotic
Describes factors that prevent the fertilization of an egg. (p. 666)

primary active transport
Active transport that uses the energy of ATP directly. (p. 148)

primary structure
The sequence of amino acids in a peptide or a protein. (p. 70)

primary transcript
The initial RNA molecule that comes off the template DNA strand. (p. 463)

primer
A short strand of DNA or RNA; in DNA replication, RNA is used as a primer for DNA synthesis. (p. 451)

probability
The likelihood of an event happening. (p. 372)

product
Atoms or molecules that are made in a chemical reaction. (p. 35)

prokaryotic
Describes a cell that does not have a nucleus; used to refer collectively to archaeons and bacteria. (p. 98)

prometaphase
The phase of mitosis in which the nuclear envelope breaks down and the microtubules of the mitotic spindle attach to chromosomes. (p. 328)

promoter
A regulatory region where RNA polymerase and associated proteins bind to the DNA molecule in the process of transcription. (p. 461)

proofreading
The process in which a DNA polymerase can immediately correct its own errors by excising and replacing a mismatched base. (p. 455)

prophase

The phase of mitosis in which the chromosomes condense and become visible through the microscope. (p. 326)

protein

A type of organic molecule that provides structural support for the cell and speeds up chemical reactions. (p. 37)

proton

An atomic particle of the nucleus that carries a positive charge. (p. 30)

punctuated equilibrium

The idea that species go through periods of relatively little change, which are interrupted by short periods of rapid change and

diversification. (p. 676)

purine

In nucleic acids, either of the bases adenine and guanine, which have a double-ring structure. (p. 78)

pyrimidine

In nucleic acids, any of the bases thymine, cytosine, and uracil, which have a single-ring structure. (p. 79)

quaternary structure

The level of protein structure that arises from the interaction of two or more polypeptide chains or subunits, each with its own tertiary structure. (p. 72)

quorum sensing

Density-dependent production of

signal molecules in bacteria that leads to population responses, such as bioluminescence or DNA uptake. (p. 278)

radiometric dating

Dating ancient materials using the decay of radioisotopes as a yardstick, including the decay of radioactive 14C^{14}C to nitrogen for time intervals up to a few tens of thousands of years, and the decay of radioactive uranium to lead for most of Earth history. (p. 624)

range

A measure of how spread out numbers in a set of numbers are. The range is calculated by determining the difference between the highest

and lowest numbers in a set of numbers. (p. 22)

reactant

Atoms or molecules that are changed in a chemical reaction. (p. 35)

reaction center

Specially configured chlorophyll molecules where light energy is converted into electron transport. (p. 223)

receptor protein

A molecule that binds to a signaling molecule and triggers a response in a target cell. (p. 138)

receptor-protein kinase

A receptor protein in cell membranes that have kinase activity that is

activated after binding to an extracellular signaling molecule. (p. 294)

recessive

Describes an allele or trait that is only expressed in homozygotes, and not expressed in heterozygotes. Two recessive alleles are needed to express the phenotype. (p. 369)

recombination

See **crossing over**.

reduction

A chemical reaction in which a molecule gains electrons and energy. (p. 214)

replication fork

The site where the parental DNA

strands separate as the DNA duplex unwinds. (p. 448)

reverse transcriptase

An RNA-dependent DNA polymerase that uses a single-stranded RNA as a template to synthesize a DNA strand that is complementary in sequence to the RNA. (p. 544)

ribonucleic acid (RNA)

A molecule chemically related to DNA that is synthesized from a DNA template and is involved in protein synthesis, among other functions. (p. 38)

ribose

A pentose sugar commonly found in RNA. (p. 56)

ribosomal RNA (rRNA)
Noncoding RNA found in all ribosomes that aid in translation. (p. 465)

ribosome
A complex structure of RNA and protein that synthesizes proteins from mRNA. (p. 96)

RNA polymerase
The enzyme that synthesizes an RNA transcript from a DNA template. (p. 460)

RNA processing
A chemical modification that converts the primary transcript into mature mRNA, enabling the RNA molecule to be transported to the cytoplasm and

recognized by the translational machinery. (p. 463)

RNA splicing

The process of joining exons and removing introns from the primary transcript. (p. 465)

RNA world hypothesis

The idea that the earliest cells relied on RNA for both information storage and catalysis. (p. 709)

root

The base of a phylogenetic tree, representing the common ancestor or group from which all the organisms on the tree evolved. (p. 564)

S phase

The phase during interphase in which

the cell copies its DNA; the S phase follows the G1[G1] phase but precedes the G2[G2] phase. (p. 325)

saturated

Describes fatty acids that do not contain double bonds; the maximum number of hydrogen atoms is attached to each carbon atom, “saturating” the carbons with hydrogen atoms. (p. 58)

scientific inquiry

A deliberate, systematic, careful, and unbiased way of learning about the natural world; the process used to ask questions and seek answers about the natural world in a deliberate and ordered way. (p. 5)

second law of thermodynamics
The principle that the transformation of energy is associated with an increase in the degree of disorder in the universe. (p. 189)

second messenger
An intermediate signaling molecule that amplifies a response inside a cell. (p. 293)

secondary active transport
Active transport that uses the energy of an electrochemical gradient to drive the movement of molecules. (p. 148)

secondary structure
The structure that results from hydrogen bonding in the polypeptide

backbone. Two kinds of secondary structures are the alpha helix (α helix) and the beta sheet (β sheet). (p. 70)

selective pressure

The full set of environmental conditions, both abiotic and biotic, that influence the evolution of a population by natural selection. (p. 576)

semiconservative replication

The mechanism of DNA replication in which each strand of a parental DNA molecule serves as a template for the synthesis of a new daughter strand. (p. 448)

sensor

In homeostasis, the component that

detects a stimulus. (p. 284)

set point

In homeostasis, the typical physiological value of a particular parameter, such as body temperature or blood glucose levels, which is actively maintained by the body with very little fluctuation. (p. 284)

sex chromosome

A chromosome associated with sex determination. (p. 352)

sex-linked gene

A gene that is only located on one of the two sex chromosomes. (p. 394)

sexual reproduction

The process of producing offspring that receive genetic material from

two parents; in eukaryotes, the process occurs through meiotic cell division and fertilization. (p. 351)

sexual selection

A form of selection that promotes traits that increase an individual's ability to find and attract mates. (p. 582)

shared character

A character or trait that is present in two or more groups of organisms. (p. 651)

signal transduction

The process by which an external signal is converted to an internal response. (p. 290)

signaling cascade

A series of chemical reactions inside of a cell that are initiated by a signal and are typically amplified to produce a large cellular response. (p. 294)

signaling molecule

A chemical messenger that functions in cell communication by affecting activities of other cells. (p. 277)

Simpson's diversity index

An equation that quantifies the diversity of species in a community. (p. 779)

single bond

A covalent bond in which two atoms share two electrons. (p. 33)

sister chromatids

The two copies of a chromosome

resulting from DNA duplication that remain connected at the centromere. (p. 325)

solute

A dissolved molecule such as the ions, amino acids, and sugars often found in a solvent such as water. (p. 156)

solute potential

The effect of solutes on the movement of water. (p. 160)

solvent

A substance that can dissolve another substance. (p. 48)

speciation

The process whereby new species are produced. (p. 668)

species

A group of individuals that are capable of interbreeding and producing viable, fertile offspring. (p. 2)

specific heat

The amount of heat required per unit mass of a substance to raise the temperature of the mass by 1 degree Celsius. (p. 46)

standard deviation

A measure of how spread out numbers in a set of numbers are. The standard deviation is calculated by taking the square root of the variance, or the average of the squared differences from the mean. (p. 22)

standard error of the mean

A measure of how far the mean of a sample is from the true mean of the whole population. The standard error of the mean is calculated by dividing the standard deviation by the square root of the number of values in a sample. (p. 24)

steroid

A type of lipid; the precursor molecule for cholesterol and steroid hormones. (p. 60)

stroma

The region of the chloroplast that surrounds the thylakoid, where the Calvin cycle takes place. (p. 218)

substrate (*S*)

A molecule acted upon by an enzyme; also called a reactant. (p. 200)

substrate-level phosphorylation
A way of generating ATP in which a phosphate group is transferred to ADP from an organic molecule, which acts as a phosphate donor or substrate. (p. 235)

surface area
The total area of the outside surface of an object. (p. 105)

surface tension
A measure of the difficulty of breaking the surface of a liquid. (p. 44)

symbiosis (plural, symbioses)
A close interaction that has evolved

between species that live together, often interdependently. (p. 172)

sympatric

Describes populations that are in the same geographic location. (p. 673)

system

A group of entities that function together. A system may be living or nonliving. (p. 4)

target cell

A cell that has receptor proteins that can bind to a specific signaling molecule. (p. 277)

telophase

The phase of mitosis in which the nuclei of the daughter cells are formed and the chromosomes uncoil

to their original state. (p. 328)

template strand

The strand of DNA that is used as a template, or model, for RNA synthesis during transcription. The template strand is also called the noncoding, antisense, and minus strand. (p. 460)

tertiary structure

The three-dimensional shape of a single polypeptide chain, usually made up of several secondary structure elements. (p. 71)

test group

The group that is exposed to the independent variable in an experiment. Also known as the **experimental group**. (p. 7)

theory

A general explanation of the world supported by a large body of experiments and observations. (p. 13)

thylakoid

A flattened sac within the chloroplast that is bounded by membranes where the light-dependent reactions of photosynthesis occur. (p. 111)

thymine (T)

A pyrimidine base. (p. 79)

tonicity

A measure of osmotic pressure; the higher the osmotic pressure, the higher the tonicity. (p. 158)

topoisomerase

An enzyme that relieves stress on the

DNA double helix that results from overwinding or underwinding during DNA replication and transcription. (p. 451)

transcription

The synthesis of RNA from a DNA template. (p. 440)

transcription factor

A protein that binds to the promoter of a gene and is necessary for transcription to take place. (p. 489)

transduction

The transfer of DNA from cell to cell by means of a virus; a form of horizontal gene transfer. (p. 521)

transfer RNA (tRNA)

Noncoding RNA that carries

individual amino acids for use in translation. (p. 465)

transformation

The conversion of cells from one state to another, as from nonvirulent to virulent, when DNA released to the environment by cell breakdown is taken up by recipient cells. In recombinant DNA technology, the introduction of recombinant DNA into a recipient cell. Transformation is a form of horizontal gene transfer. (p. 521)

transition state

The brief time in a chemical reaction in which chemical bonds in the reactants are broken and new bonds in the product are formed. (p. 198)

translation

The synthesis of a polypeptide chain corresponding to the coding sequence present in a molecule of messenger RNA. (p. 440)

translation elongation

The process by which successive amino acids are added one by one to a growing polypeptide chain during translation. (p. 475)

translation initiation

The process by which translation begins. During initiation, the initiator AUG codon is recognized, and Met is established as the first amino acid in the new polypeptide chain. (p. 475)

translation termination

The process by which the addition of amino acids stops during translation and the completed polypeptide chain is released from the ribosome. (p. 475)

transmembrane protein

A protein that spans the entire lipid bilayer; most integral membrane proteins are transmembrane proteins. (p. 139)

transport protein

A membrane protein that moves molecules across the cell membrane. (p. 138)

transposition

The process by which a DNA sequence moves from one location to

another in a DNA molecule. (p. 515)

triacylglycerol

A lipid composed of a glycerol backbone and three fatty acids. (p. 58)

triploidy

The condition of having three complete sets of chromosomes in the genome. (p. 517)

trophic cascade

When indirect effects are initiated by the presence of a predator. (p. 789)

trophic levels

An arrangement of producers and consumers into successive levels that represents the movement of energy. (p. 741)

turgor pressure

Pressure within a cell resulting from the movement of water into the cell by osmosis. (p. 114)

Turner syndrome

A condition in humans in which females have only one *X* chromosome. (p. 426)

unsaturated

Describes fatty acids that contain carbon–carbon double bonds. (p. 59)

uracil (U)

A pyrimidine base in RNA, where it replaces thymine found in DNA. (p. 84)

vacuole

A membrane-bound organelle

present in some cells, including plant and fungal cells, that contains fluid, ions, and other molecules; in some cases, it absorbs water and contributes to turgor pressure. (p. 114)

valence electron

An electron in the outermost energy level of an atom. (p. 31)

van der Waals force

An interaction of temporarily polarized molecules because of the attraction of opposite charges. (p. 59)

vesicle

A small membrane-enclosed sac that transports substances within the cell. (p. 105)

vestigial structure

A structure that has lost its original function over time and is now much reduced in size. (p. 619)

virus

A small infectious agent that contains a nucleic acid genome packaged inside a protein coat called a capsid; some viruses also have a phospholipid envelope. (p. 541)

visible light

The portion of the electromagnetic spectrum apparent to our eyes. (p. 221)

volume

The amount of space an object occupies. (p. 120)

water potential

A parameter that combines all the physical and chemical factors that influence the movement of water, such as pressure, osmosis, and gravity; water moves from regions of higher water potential to regions of lower water potential. (p. 157)

zygote

The diploid cell formed by the fusion of two gametes. (p. 360)

Glossary/Glosario

GLOSSARY	GLOSARIO
3′ end	**extremo 3′**
The extreme of a DNA or RNA molecule that has a free 3′ hydroxyl group. By convention, the 3′ end is considered the last nucleotide. (p. 80)	El extremo de una molécula de ADN o ARN que tiene un grupo hidroxilo libre en 3′. Por convención, el extremo 3′ se considera el último nucleótido.
5′ end	**extremo 5′**
The extreme of a DNA or RNA molecule that has a free 5′ phosphate group. By convention, the 5′ end is considered the first nucleotide. (p. 80)	El extremo de una molécula de ADN o ARN que tiene un grupo fosfato libre en 5′. Por convención, el extremo 5′ se considera el primer nucleótido.
A	
abiótico	
Pertaining to nonliving things. (p. 4)	Perteneciente a lo inerte.
ácido	
A molecule that donates H^+ ions to a solution. The concentration of hydrogen ions is greater than that in pure water.	Molécula que dona iones H^+ a una solución. Tiene una concentración de iones de hidrógeno mayor que la concentración de

hydroxide ion, pH H acid (p. 49)

activation energy (EA) (E_A)

The energy input necessary to achieve the transition state. (p. 199)

activator

A compound that increases the activity of an enzyme. (p. 205)

active site

The portion of an enzyme that binds substrates and converts them into products. (p. 202)

active transport

The movement of substances through a cell membrane against a concentration gradient or concentration gradient. (p. 148) requiere un aporte de energía.

adaptation

Process that allows an organism and its environment. (p. 561)

adaptive radiation

Period of rapid diversification in which a diversification of species occurs with adaptations to specific niches. (p. 674)

addition rule of probabilities

Rule that states that the probability of two

adaptive radiation

Period of rapid diversification in which a diversification of species occurs with adaptations to specific niches. (p. 674)

addition rule of probabilities

Rule that states that the probability of two

mutually exclusive events is the sum of their individual probabilities. (p. 832)

probabilidades individuales.

adenine (A)

A purine base. (p. 79)

Una base púrica.

adenosine diphosphate (ADP)

A chemical relative of ATP that is composed of a base adenine, a five-carbon sugar ribose, and two phosphate groups. ADP contains less chemical energy than ATP. (p. 187)

Pariente químico del ATP que está compuesto de una base adenina, un azúcar de cinco carbonos ribosa, y dos grupos fosfato. El ADP contiene menos energía química que el ATP.

adenosine triphosphate (ATP)

The molecule that provides energy in a form that all cells can use. (p. 96)

La molécula que proporciona energía en una forma que todas las células pueden utilizar fácilmente para realizar su trabajo.

adhesion

The tendency of water molecules to stick to other polar or charged molecules. (p. 44)

La tendencia de las moléculas de agua a adherirse a otras moléculas polares o cargadas.

agonist

A ligand that binds a receptor and activates a response. (p. 305)

Un ligando que se une a un receptor y activa una respuesta.

alleles

Different forms of a gene, corresponding to different DNA sequences. (p. 369)

Diferentes formas de un gen, correspondiendo a diferentes secuencias de ADN

allopatric

Describes populations that are geographically separated from each other. (p. 668)

Describe poblaciones que están geográficamente separadas entre sí.

allosteric site

Parte de la enzima distinta del sitio activo. (p. 206)

alpha helix (hélice α)

Uno de los dos principales tipos de estructura secundaria de las proteínas. (p. 70)

alternative hypothesis

Hipótesis que predice la variable independiente de un experimento tendrá un efecto real y que habrá una diferencia entre los dos grupos de datos recolectados por los experimentos. (p. 11)

alternative splicing

Proceso por el cual los exones se unen y se forman los intrones se remueven during RNA processing. A diferencia de splicing de ARN, Una de splicing de ARN se puede en diferentes ARNs y (p. 465)

amino acid

Subunidad básica de las proteínas. (p. 38)

amplification

Proceso en el que un pequeño número de señales se realizan para generar una gran respuesta (p. 293)

allosteric site

Parte de la enzima distinta del sitio activo. (p. 206)

alpha helix (hélice α)

Uno de los dos principales tipos de estructura secundaria de las proteínas. (p. 70)

alternative hypothesis

Hypothesis that predicts a variable independent experiment will have a real effect, and there will be a difference between the data collected from the experimental and experimental groups. (p. 11)

alternative splicing

The process by which exons are joined together and introns are removed during RNA processing. A diferencia de splicing de ARN, Una de splicing de ARN se puede en diferentes ARNs and different proteínas. (p. 465)

amino acid

The subunit of proteins. (p. 38)

amplification

The process in which a small number of signals are realized to generate a very large response (p. 293)

allosteric site

Parte de la enzima distinta del sitio activo. (p. 206)

alpha helix (hélice α)

Uno de los dos principales tipos de estructura secundaria de las proteínas. (p. 70)

alternative hypothesis

Hipótesis que predice la variable independiente de un experimento tendrá un efecto real y que habrá una diferencia entre los dos grupos de datos recolectados por los experimentos. (p. 11)

alternative splicing

Proceso por el cual los exones se unen y se forman los intrones se remueven during RNA processing. A diferencia de splicing de ARN, Una de splicing de ARN se puede en diferentes ARNs and different proteínas. (p. 465)

amino acid

Subunidad básica de las proteínas. (p. 38)

amplification

Proceso en el que un pequeño número de señales se realizan para generar una gran respuesta (p. 293)

anabolismo

The set of chemical reactions that build complex molecules from simpler units using the form of ATP energy, usually in the form of ATP. Anabolic reactions result in net energy storage within cells and the organism. (p. 193)

The set of chemical reactions that build complex molecules from simpler units using energy, usually in the form of ATP. Anabolic reactions result in net energy storage within cells and the organism. (p. 193)

anafase

The phase of mitosis in which sister chromatids separate. (p. 328)

The phase of mitosis in which sister chromatids separate.

antagonista

Ligand that binds a receptor and inhibits a response. (p. 305)

Ligand that binds a receptor and inhibits a response.

anticodón

The sequence of three nucleotides in a tRNA molecule, complementary with the corresponding codon in an mRNA molecule. (p. 471)

The sequence of three nucleotides in a tRNA molecule, complementary with the corresponding codon in an mRNA molecule.

antiparalelo

Orientación opuesta de las dos cadenas de DNA en la molécula de ADN. (p. 82)

Orientación opuesta de las dos cadenas de DNA en la molécula de ADN.

apoptosis

The genetically programmed death of a cell. (p. 340)

The genetically programmed death of a cell.

aquaporina

Proteína de canal que permite que el agua

Proteína de canal que permite que el agua

cell membrane

The cell membrane allows many molecules to pass through the lipid bilayer. (p. 147)

archaea

One of the three domains of life, consisting of prokaryotic organisms that differ from bacteria in many aspects of their molecular biology. (p. 98)

artificial selection

Form of selection similar to natural selection, but with selection done intentionally by humans, usually with a specific goal in mind, such as increasing milk yield in a herd. (p. 580)

asexual reproduction

The reproduction of organisms in which offspring inherit DNA from a single parent. (p. 323)

atom

The basic building block of matter. (p. 26)

atomic mass

The total mass of an atom, consisting of the number of protons and neutrons in the atom. (p. 30)

atomic number

The number of protons in an element. (p. 30)

ATP synthase

ATP synthase

Enzyme that couples the movement of protons through the cell membrane with the synthesis of ATP. (p. 225)

autosome

Cualquier cromosoma que no es sexual. (p. 352)

autótrofo

Organismo que obtiene energía por fotosíntesis o quimiosíntesis. También se conoce como productor. (p. 741)

B

bacteria

Uno de los tres dominios de la vida, formado por organismos unicelulares que difieren de las arqueas en muchos aspectos moleculares. (p. 98)

base

Molécula que acepta iones H^+ y los elimina de la solución. Cuando la concentración de iones de hidrógeno es menor que la concentración de iones de hidróxido, la solución es básica. (p. 40)

beta sheet (lámina β)

Uno de los tres principales tipos de estructura secundaria que se encuentran en las proteínas. (p. 71)

biodiversidad

biodiversidad

Biodiversidad, el número total de especies, o, en términos más precisos, la diversidad genética, especies, ecosystems, biomas, life histories, phylogenetic groups, ecosystems (p. 562)

biología de la conservación

Ciencia de la biodiversidad y la conservación de la biodiversidad y la conservación de la biodiversidad y la conservación

vivos.

bottleneck botella

Reducción extrema y generalmente temporal del tamaño de una población que puede llevar a una reducción de la diversidad genética. (p. 613)

deriva genética genetic drift

C

ciclo de Calvin Calvin cycle

Proceso en el cual el dióxido de carbono se reduce para sintetizar **carbohidratos,** usando ATP y NADPH como fuentes de energía. (p. 217)

cáncer cancer

Condición de división celular descontrolada, que puede resultar en el desarrollo de tumores y diseminarse. (p. 336)

carbohidrato carbohydrate

Tipo de molécula orgánica. (p. 38)

carbono-14 (^{14}C) carbon-14 (^{14}C)

Isótopo radiactivo del carbono frecuentemente utilizado en la datación radiométrica. (p. 624)

proteína portadora carrier protein

Proteína que facilita la movimiento de moléculas a través de una membrana. (p. 147)

capacidad de carga carrying capacity (K)

Cantidad de individuos que puede soportar un ambiente dado. (p. 760)

catabolismo

The set of chemical reactions that break down complex molecules into simpler ones, in a process by which ATP is produced to satisfy the cell's energetic needs. (p. 22)

El conjunto de reacciones que descomponen las moléculas más complejas para obtener ATP y satisfacer las necesidades energéticas de la célula.

catalizador

A compound that increases the rate of a chemical reaction, but remains unaltered. (p. 197)

Compuesto que aumenta la velocidad de una reacción química, pero que sale del proceso inalterado.

ciclo celular

The cell cycle is the stages that make up the life cycle of a cell, including DNA replication and cell division. (p. 324)

El ciclo de vida de la célula, incluyendo la replicación del ADN y la división celular.

división celular

The process by which a cell reproduces to two daughter cells. (p. 322)

Proceso en el que una célula se reproduce en dos células hijas.

teoría celular

The set of ideas that states that the cell is the center of life. It states that the cell is the fundamental unit of life, and that organisms are made of cells, and that cells arise from preexisting cells. (p. 13)

Conjunto de ideas que sitúa la célula en el centro de la vida. Afirma que la célula es la unidad fundamental de la vida, que los organismos están formados por células, y que las células surgen de células preexistentes.

célula

The simplest self-replicating entity that can exist as an independent unit of life. (p.10)

unidad de vida independiente.

cell membrane

The membrane that surrounds the cytoplasm of the cell, separating the cell from the external environment. It also controls the movement of substances into and out of the cell. (p.58)

cellular respiration

Series of chemical reactions in which organic molecules are oxidized and converted into ATP. (p.110)

central dogma

The concept that information normally flows from DNA to RNA to protein. (p.84)

centrómero

Región del ADN en la que las cromátidas hermanas se unen. También es el lugar en el que se sujeta el husillo mitótico para impulsar el movimiento de los cromosomas durante la mitosis. (p.325)

centrosome

Estructura compacta que se sitúa cerca del núcleo

organizado en forma de túbulos. (p. 326)

canal de proteína

Proteína de membrana con un pasaje que allows the movement of molecules through it. (p. 147)

carácter

Atributo anatómico, fisiológico, o molecular de un organismo que varía entre organisms among taxa. (p. 651)

punto de control

Punto de transición entre las fases del cell cycle. (p. 338)

enlace químico

Fuerza de atracción entre átomos that holds them together. (p. 33)

energía química

Forma de energía potencial que se conserva en los enlaces químicos entre pares de átomos en una molécula. (p. 185)

reacción química

Proceso por el cual una molécula es transformed into different molecules. (p. 35)

quimiosmosis

Movimiento de iones, como los hydrogen ions (protones), from una región de high concentración a otra

to a region of low concentration a través de una membrana selectiva, similar to permeable, sin fase líquida o iones. El agua por ósmosis. En la mitocondria y los cloroplastos, la quimiosmosis proporciona la síntesis de ATP por ATPasa. (p. 251)

síntesis de ATP mediante la ATPasa.

chemiosmosis

The biochemical process in which energy of chemical compounds is used to drive ATP synthesis. (p. 740)

proceso bioquímico en el cual la energía de los compuestos químicos se usa para producir azúcares. (p. 740)

chi-square (χ²) test

A statistical test that determines whether the number of observed events differs from the expected number of events. (p. 374)

prueba de chi cuadrado (χ 2) (χ^2)

Prueba estadística que determina si el número de eventos observados difiere de la cantidad esperada de eventos. (p. 374)

chlorophyll

The major photosynthetic pigment in the thylakoid membranes; it plays a key role in the cell's ability to capture energy from sunlight. (p. 112)

contenido de clorofila

Pigmento fotosintético principal en las membranas tilacoides; desempeña un papel clave en la capacidad de la célula para capturar energía de la luz solar.

chloroplast

An organelle in plant and algal cells that converts energy of sunlight into chemical energy by synthesizing sugars. (p. 111)

cloroplasto

Orgánulo de las células vegetales y algas que convierte la energía de la luz solar en energía química mediante la síntesis de azúcares simples.

chromatin

Consider the ADN, ARN y proteínas que llena el núcleo de las células eucariotas.

Consider the DNA, RNA, and protein that fills the nucleus. (p. 326)

cromosoma

Estructura celular que contiene el material genético de las células, formada por una sola molécula de ADN asociada con proteínas.

A cellular structure containing the genetic material in cells, consisting of a single DNA molecule with associated proteins. (p. 324)

cladograma

Tipo de árbol filogenético que muestra las relaciones evolutivas entre grupos.

A type of phylogenetic tree that shows the evolutionary relationships among groups. (p. 650)

codón

Grupo de tres nucleótidos adyacentes en el ARN que especifica un aminoácido en una proteína durante la síntesis proteica.

A group of three adjacent nucleotides in mRNA that specifies a particular amino acid in a protein during protein synthesis. (p. 471)

cohesión

Tendencia de las moléculas de agua a adherirse unas a las otras debido a los enlaces de hidrógeno.

Tendency of water molecules to stick to one another due to hydrogen bonding between them. (p. 44)

commensalismo

Interacción en la cual una especie recibe un beneficio mientras que la otra no se ve perjudicada ni beneficiada.

An interaction in which one species receives a benefit while the other species is neither harmed nor helped. (p. 787)

competencia

Interacción entre especies que requieren los mismos recursos limitados.

An interaction between species that require the same limited resource. (p. 786)

complementario

Describes the relationship between purines and pyrimidines, in which the base A pairs only with T, and G pairs only with C. (p. 83)

complex carbohydrate
carbohidrato complejo
A long, branched chain of monosaccharides. (p. 57)

concentration gradient
gradiente de concentración
A difference in concentration of a substance, with regions of higher and lower concentration. (p. 146)

conjugation
conjugación
Transferencia directa de ADN (p. 1) A generalmente de forma de plásmido, de una célula a otra; (p. 520) mecanismo de transferencia horizontal de genes.

contractile vacuole
vacuola contráctil
Orgánulo de algunos protistas que actively expels water out of the cell by osmosis. (p. 519)

control group
grupo de control
A group that is not exposed to the independent variable in an experiment, or is not, expected to show a change, also known as **negative control**, *control negativo*, or simplemente *control*. (p. 7)

experimental group
grupo experimental

Experimento en el que se realiza una prueba a un grupo de estudiantes. Las condiciones y el entorno son casi idénticos para ambos grupos, excepto en un aspecto (el grupo experimental recibe tal estímulo, mientras que el grupo control no.

evolución convergente

Evolución independiente de rasgos similares en diferentes especies como resultado de entornos similares y presiones selectivas (p. 577)

comportamiento cooperativo

Comportamiento en el que los miembros de una especie interactúan para beneficio mutuo (p. 731)

enlace covalente

Enlace en el que dos átomos comparten un par de electrones (p. 33)

entrecruzamiento cromosómico

Proceso de la profase I de meiosis en el que dos cromátidas de cada cromosoma se unen y se intercambian segmentos (p. 354)

recombination

recombinación.

cyclic adenosine monophosphate (cAMP)

Derivado del ATP que sirve como segundo mensajero intracelular en muchas rutas de signal

transducción de señales. (p. 293)

cyclin-dependent kinase (CDK)

Enzima que se activa al unirse a la ciclina apropiada, y que puede cambiar su actividad transferir un grupo fosfato a una proteína objetivo. (p. 337)

cyclins

Familia de varias proteínas que se producen en distintas cantidades durante las fases del ciclo celular, y que conducen y regulan las dependencias del ciclo celular. (p. 337)

cytokinesis

Etapa de la M en la cual el citosol, orgánelos y núcleos se dividen en dos células hijas. (p. 324)

cytoplasm

Región de la célula fuera del núcleo. (p. 98)

cytosine (C)

Una base nitrogenada. (p. 79)

cytoskeleton

Entramado proteico que ayuda a la célula a mantener su forma. (p. 112)

citosol

cytosol

La región de la célula situada dentro de la membrana celular pero fuera de los orgánulos, similar en ambiente a los que rodean los orgánulos. (p. 101)

The region of the cell inside the cell membrane but outside the organelles, similar in environment to that surrounding the organelles. (p. 101)

D

deshidratación síntesis por deshidratación

dehydration synthesis

Reacción en la cual dos moléculas forman un enlace al reaccionar entre ellas y liberan una molécula de agua. Las reacciones de síntesis de deshidratación construyen large moléculas grandes a partir de sus subunidades más pequeñas. También se denomina reacción de deshidratación. (p. 50)

A reaction in which two molecules form a new chemical bond by reacting with each other and release a molecule of water. Dehydration reactions build large molecules from their subunits. Also called dehydration reaction. (p. 50)

desnaturalización

denaturation

Desplegar una proteína para que no pueda realizar su función, ya que la forma de una proteína está estrechamente relacionada con su funcionamiento. (p. 204)

Unfolding a protein so that it no longer can perform its function, as the shape of a protein is closely related to its functioning. (p. 204)

factor dependiente de la densidad

density-dependent factor

Factores que limitan el crecimiento de una población a medida que aumenta su tamaño. (p. 766)

Factors that limit population growth as its size increases. (p. 766)

factor independiente de la densidad

density-independent factor

Factores que reducen la densidad de una población independientemente de su tamaño. (p. 765)

Factors that reduce the density of a population irrespective of its size. (p. 765)

ácido desoxirribonucleico (ADN)

deoxyribonucleic acid (DNA)

ácido nucleico

La molécula portadora de la información genética de los organismos.

desoxirribosa

Un azúcar pentosa (p. 56)

variable dependiente

La variable que se está probando, observando, medida, y que puede cambiar debido a la variable independiente. (p. 8)

derivado

Algo que ha evolucionado a partir de otra cosa; en evolución, involucrado en la evolución. (p. 652)

diferenciación

El proceso por el cual las células se vuelven cada vez más especializadas. (p. 499)

difusión

Movimiento neto de moléculas de una área de mayor concentración a otra de menor concentración. (p. 124)

híbrido

Un individuo que tiene dos rasgos diferentes. (p. 378)

diploide

Célula con dos series de cromosomas (denoted as $2n$). (p. 351)

directionality / **direccionalidad**

A property of a structure that exists in one direction but not in the other. Also known as **polarity**. (p. 80)

Asimetría en una estructura que existe en una dirección pero no en la otra. También se conoce como **polaridad**.

disaccharide / **disacárido**

Two simple sugars joined by a covalent bond; an example is sucrose. (p. 57)

Dos azúcares simples unidos por un enlace covalente; un ejemplo es la sacarosa.

distribution / **distribución**

A description, which typically takes the form of a histogram, of the possible values for a particular variable and their frequencies. The distribution describes the dispersion of the data and the frequency with which each value occurs. (p. 21)

Descripción, que típicamente toma la forma de un histograma, de los valores posibles de una variable y sus frecuencias. La distribución describe la dispersión de los datos y la frecuencia con la que ocurre cada valor.

divergent evolution / **evolución divergente**

The process by which groups of organisms become genetically and physically different from each other over time. (p. 668)

El proceso por el cual dos grupos de organismos se diferencian genética y físicamente entre sí a lo largo del tiempo.

DNA editing / **edición del ADN**

Techniques used to "rewrite" a nucleotide sequence at specific locations in a genome. Scientists can use these techniques to correct mutations that cause genetic disorders. (p. 536)

Técnicas utilizadas para "reescribir" una secuencia de nucleótidos en ubicaciones específicas de un genoma. Los científicos pueden usar estas técnicas para corregir mutaciones que causan trastornos genéticos, restaurando la función normal de los genes.

DNA ligase / **ADN ligasa**

An enzyme that joins fragments of DNA.

Enzima que une los fragmentos de ADN.

together. (p. 454)

DNA polymerase

ADN polimerasa

An enzyme that is a critical component of a large protein complex that carries out DNA replication. (p. 451)

Enzima que forma parte del complejo proteico de replicación del ADN

DNA replication

replicación del ADN

The process of duplication of DNA molecule, in which the parental strands separate and new strands are made. (p. 339)

El proceso de duplicación de una molécula de ADN, en la que las cadenas parentales se separan y se forman cadenas nuevas. (p. 339)

domain

dominio

One of the three large branches of the tree of life: Eukarya, Bacteria, or Archaea. (p. 98)

Una de las tres grandes ramas del árbol de la vida: Eukarya, Bacteria o Archaea. (p. 98)

dominant

dominante

Describes an allele or trait that is expressed in heterozygotes. Only one dominant allele is needed to express the phenotype. (p. 369)

Describe un alelo o rasgo que se expresa en heterocigotos. Solo se necesita un alelo dominante para expresar el fenotipo. (p. 369)

double bond

doble enlace

A covalent bond in which two atoms share two pairs of electrons. (p. 13)

Enlace covalente en el que dos átomos comparten dos pares de electrones. (p. 13)

double helix

doble hélice

The structure formed by two strands of nucleotides in complementary base pairing with each other. (p. 81)

Estructura formada por dos cadenas de nucleótidos en apareamiento de bases complementarias que se enroscan entre sí. (p. 81)

Down syndrome

síndrome de Down

A condition in humans caused by an extra

presencia de una copia del cromosoma 21
Presencia de una copia del cromosoma 21. (p. 425)

E

ectotermo
Animal que obtiene la mayor parte del calor que utiliza para calentar su cuerpo del ambiente.

electrón
Partícula atómica que se desplaza alrededor del núcleo y tiene carga negativa. (p. 30)

electrón-voltio
Véase **energía de ionización.** (p. 35)

electronegatividad
Diferencia en la capacidad de los átomos para atraer electrones. (p. 34)

elemento
Sustancia química que no puede dividirse en otras más sencillas. (p. 30)

enfermedad emergente
Enfermedad infecciosa que ha aparecido recientemente y/o se ha extendido rápidamente.

endergónico
Describe a reacciones con ΔG positivo que no se producen espontáneamente y que, por tanto, requieren energía. (p. 547)

energía
Capacidad de realizar trabajo. (p. 191)

endergónico

Una reacción que requiere la aportación de energía. (pág. 92)

endocitosis

Proceso en el que una vesícula se desprende de la membrana celular, ingiriendo material del exterior de la célula. La vesícula, que puede fusionarse con otras. (p. 151)

sistema endomembranoso

Sistema que se encuentra en las células eucariotas que incluye la envoltura nuclear, el retículo endoplásmico, el aparato de Golgi, los lisosomas, la membrana celular y las vesículas que se intercambian entre ellos. (p. 106)

retículo endoplásmico (RE)

Orgánulo compuesto por una red de membranas que participa en la síntesis de proteínas y lípidos. (p. 107)

endosimbiosis

Simbiosis en la que un organismo vive dentro del otro. (p. 173)

endotermo

Animal que produce en gran parte su calor por subproductos metabólicos y mantiene una temperatura corporal cálida constante. (pág. 736)

energética

Ciencia que estudia las propiedades de la energía y la energía en sistemas biológicos, químicos y físicos. (p. 4)

energía

Área en la que se encuentra el núcleo. También llamada **electrosfera**. (p. 31)

energía

La capacidad de trabajar. (p. 4)

entropía

La cantidad de desorden, o el número de posiciones y movimientos posibles de moléculas, átomos, o partículas. (p. 188)

enzima

Proteína que funciona como catalizador para acelerar la velocidad de una reacción química. (p. 107)

epigenética

Describe los efectos en la expresión genética de diferencias en el empaquetamiento del ADN y la organización de los cromosomas, como modificaciones en las histonas en la estructura de la cromatina. (p. 193)

eukarya

Uno de los tres dominios de la vida, en el cual

have a true nucleus. (p. 101)

verdadero núcleo.

eukaryotic

Describes a cell that has a nucleus; used to refer to animals, plants, fungi, and protists. (p. 98)

Describe una célula que tiene un núcleo; se refiere a animales, plantas, hongos y protistas.

evolution

Change in the genetic makeup of a population over time. (p. 2)

Cambio en la composición genética de una población a lo largo del tiempo.

evolutionarily conserved

Characteristics that persist relatively unchanged through diversification of a group of organisms and, for a trait, similar in related species. (p. 503)

Características que persisten relativamente inalteradas tras la diversificación de un grupo de organismos y, por un rasgo, similares en especies relacionadas.

exergónico

Describes a reaction with a negative ΔG that proceeds spontaneously and releases energy. (p. 191)

Describe una reacción con un ΔG negativo que ocurre espontáneamente y libera energía.

exocytosis

The process in which a vesicle fuses with the cell membrane and expels its contents into the extracellular space. (p. 150)

Proceso en el que una vesícula se funde con la membrana celular y expulsa su contenido al espacio extracelular.

exón

A sequence that is retained in mature RNA after splicing, and is then expressed in the protein. (p. 465)

Secuencia que permanece en el ARN maduro después del empalme y que se expresa en la proteína.

experimental group

Véase **Test group** (p. 7)

exponential growth model

Model of population that continues to grow rápidamente en el tiempo de forma exponencial. (p. 758)

extinction

La pérdida de un grupo de organismos, típicamente a nivel de una especie.

F

facilitated diffusion

Difusión a través de una membrana celular mediante una proteína transmembranal, como un canal o transportadora. (p. 147)

fatty acid

Cadena larga de carbono con un grupo carboxyl en el final. Ácidos grasos se unen a glicerol para formar triacilglicerol, for lípido utilizado para el almacenamiento de energía.

fermentation

Serie de reacciones metabólicas que producen ATP a partir de la oxidación parcial de moléculas orgánicas sin fosforilación oxidativa y sin un aceptor de electrones, como el oxígeno. (p. 254)

primera ley de la termodinámica

La ley de conservación de la energía, que establece que la energía no puede crearse ni destruirse, sólo cambia de forma o se transforma de una forma into another. (p. 188)

aptitud

Medida de la capacidad de un individuo para sobrevivir y reproducirse en un entorno determinado; se refiere al grado del individuo es genéticamente representado en la next generación. (p. 262)

modelo de mosaico fluido

Modelo propuesto que describe la bicapa lipídica como una estructura dinámica que permite el movimiento lateral de las moléculas dentro de la membrana, lo cual es esencial para su fluidez, permeabilidad y funcionalidad. (p. 141)

fósil

Los restos de organismos que vivieron en el pasado. (p. 620)

efecto fundador

Tipo de deriva genética que ocurre cuando un grupo de individuos establece una nueva población. (p. 603)

grupo funcional

Grupo de átomos que tiene una

propiedad química property or trait, independientemente de la que está unida. (p. 55)

G

G protein-coupled receptor

Receptor de membrana celular asociado con una proteína G que altera la actividad de la adenilil ciclasa y otros generadores de segundos mensajeros en las células diana. (p. 293)

G0 phase

The phase of the cell cycle in which cells pause between M phase and S phase; it may last for days or longer than a year. (p. 326)

G1 phase

The phase of the interphase in which the cell synthesizes proteins regulatorias controlling the eukaryotic cell cycle. (p. 325)

G2 phase

The phase of the interphase después de la replicación del ADN, caracterizada por el aumento del contenido celular. (p. 325)

gameto

Célula reproductora haploide, o gameto, que se funde con otra para formar un cigoto diploide. En

G protein

Proteína de membrana celular asociada con la actividad de la adenilil ciclasa y otros generadores de segundos mensajeros en las células diana. (p. 293)

G0 phase

The phase of the cell cycle in which cells pause between M phase and S phase; it may last for days or longer than a year. (p. 326)

G1 phase

The phase of the interphase in which the cell synthesizes proteins regulatorias controlling the eukaryotic cell cycle. (p. 325)

G2 phase

The phase of the interphase después de la replicación del ADN, caracterizada por el aumento del contenido de proteínas. (p. 325)

ovum

Female reproductive cell; the counterpart of the spermatozoid in the male. (p. 356)

gel electrophoresis

Technique used to separate DNA and RNA based on size and charge, using an electric current to move molecules through a jelly-like substance. (p. 529)

gene expression

The production of a protein, the "turning on" of a gene. (p. 436)

gene flow

The movement of alleles from one population to another through the migration of individuals between populations. (p. 605)

gene regulation

The ways in which cells control gene expression. (p. 440)

gene

The unit of DNA that corresponds to a more or less of a protein or RNA sequence that contains the instructions to a specific protein or noncoding RNA. (p. 1)

genetic code

The three-letter codons that specify amino acids, or stop signals, in a protein. (p. 356)

genetic

Pertaining to genes. (p. 1)

genetic drift

Random change in allele frequencies in a population due to chance events. (p. 605)

genetic

Pertaining to genes. (p. 1)

genetic code

The three-letter codons that specify amino acids, or stop signals, in a protein. (p. 356)

The correspondence between codons and amino acids, in which 20 amino acids are specified by 64 codons. (p. 473)

correspondencia entre codones y aminoácidos, en la que 20 aminoácidos son especificados por 64 codones. (p. 473)

genetic drift

A random change in the frequency of an allele due to chance. (p. 603)

deriva genética

Cambio aleatorio en la frecuencia de un alelo debido al azar. (p. 603)

genetic variation

The range of different types of genes found among individuals. (p. 351)

variación genética

La gama de diferentes tipos de genes que se encuentran entre los individuos. (p. 351)

genetically modified organism (GMO)

An organism that has been genetically engineered, such as a virus or bacteria modified to produce a drug, agricultural crops, and domestic animals; also called a transgenic organism. (p. 535)

organismo genéticamente modificado (OGM)

Un organismo que ha sido alterado genéticamente, por ejemplo, un virus o bacteria modificado para producir una droga, cultivos agrícolas y animales domésticos; también se llama organismo transgénico.

genome

All the genetic information that an individual, or a species, contains. (p. 1)

genoma

Toda la información genética que contiene un individuo, o una especie.

genotype

The set of genes that an organism carries. (p. 350)

genotipo

El conjunto de genes que un organismo carga. (p. 350)

Gibbs free energy (G)

The amount of energy available to do work. (p. 191)

energía libre de Gibbs (G)

La cantidad de energía disponible para realizar trabajo.

glycerol

A 3-carbon molecule with hydroxyl groups at

glicerol

Molécula de 3 carbonos con grupos hidroxilos

está unido a un grupo hidroxilo en posición 1 del triacilglicerol (p. 58)

glucolípido

Carbohydrate that is covalently linked to a lípido (p. 141)

glucólisis

Descomposición de la glucosa en piruvato, la primera etapa de la respiración (p. 237)

glucoproteína

Carbohydrate that is covalently linked to a proteína (p. 141)

Golgi apparatus

Orgánulo que modifica las proteínas y los lípidos producidos en el retículo endoplasmático y los clasifica y envía a su destino final (p. 108)

gradualismo

La idea de que las especies cambian lentamente con el tiempo (p. 576)

granas (singular, granum)

Apilamientos de membranas en los cloroplastos (p. 111)

GTP cap

La modificación del extremo 5′ de la primera transcripción primaria mediante la adición de un

gametocyte

Cualquier célula que produce gametos por meiosis (p. 287)

gene

Unidad de herencia que ocupa un lugar específico en un cromosoma (p. 76)

genetic code

Conjunto de tripletes de nucleótidos que especifican los aminoácidos en las proteínas (p. 308)

genetic drift

Cambios aleatorios en las frecuencias alélicas de una población (p. 576)

genetic engineering

Manipulación de genes para producir nuevas características en los organismos (p. 361)

genetic map

Representación de los genes y otros rasgos genéticos en un cromosoma (p. 76)

genetic recombination

Formación de combinaciones de genes que no estaban presentes en los progenitores (p. 76)

genetic variation

Diferencias en los genotipos de los individuos de una población (p. 576)

genome

Todo el material genético de un organismo (p. 361)

genotype

Conjunto de genes de un individuo (p. 76)

germ layer

Capa de tejido embrionario que se forma durante la gastrulación (p. 1100)

gene flow

Movimiento de genes entre poblaciones (p. 576)

gene pool

Conjunto de genes de una población (p. 576)

gene therapy

Tratamiento de una enfermedad genética mediante la introducción de genes en las células afectadas (p. 361)

gene transfer

Introducción de genes en una célula (p. 361)

genetic

Relacionado con los genes (p. 76)

un nucleótido especial con un enlace químico inusual, también se denomina linkage, also called a 5′ cap. (p. 464)

caperuza 5′.

guanine (G)

Una base purínica. (p. 79)

H

half-life

El tiempo que tarda una determinada cantidad de reactivo radiactivo en reducirse a la mitad de su valor inicial. La vida media de un elemento es el tiempo que tarda en descomponerse la mitad de los átomos de una muestra determinada de una sustancia. (p. 625)

haploide

Célula con una sola serie de cromosomas (denoted as $1n$). (p. 352)

Hardy-Weinberg equilibrium

Estado en el que las frecuencias de alelos y genotipos no cambian de un tiempo a otro, implying la falta de evolución y otras fuerzas evolutivas. (p. 607)

helicase

Enzima que separa las dos cadenas de ADN en la horquilla de replicación para que cada can

hebra de ADN

Una de las dos cadenas de ADN. (p. 151)

heterótrofo

Organismo que obtiene energía y carbono de otros organismos. También se conoce como consumidor. (p. 741)

heterocigoto

Condición en la que un individuo posee dos alelos diferentes para un carácter determinado.

homeostasis

La regulación activa y el mantenimiento de un estado fisiológico estable frente a un cambio externo. (p. 95)

homologos/homólogos

Dos cromosomas que son similares en tamaño y forma, y que llevan los mismos genes. (p. 352)

homocigoto

Condición en la que un individuo posee dos alelos idénticos para un determinado carácter. (p. 370)

transferencia horizontal de genes

Transferencia de material genético entre organismos que no son padres y hijos. (p. 520)

hormona

Molécula señal que se transporta en la

hebra de ADN

One of the two DNA strands. (p. 151)

heterotrophs

Organisms that obtain energy by eating other organisms. Also known as consumers. (p. 741)

heterozygote

A condition in which an individual possesses two different alleles for a given gene. (p. 317)

homeostasis

The active maintenance of a stable physiological state in the face of a changing external environment. (p. 95)

homologous chromosomes

Two chromosomes that are similar in size and shape, and that carry the same genes. (p. 352)

homozygote

A condition in which an individual possesses two identical alleles for a determined character. (p. 370)

horizontal gene transfer

Transfer of genetic material between organisms that are not parents and offspring. (p. 520)

hormone

A signaling molecule that is transported in the

sistema endocrino
Un sistema de señalización por hormonas. (p. 279)

enlace de hidrógeno
Un enlace débil entre un átomo de hidrógeno con una carga positiva y un átomo electronegativo de otra molécula. Las moléculas de agua, por ejemplo, forman enlaces de hidrógeno entre el hidrógeno de un átomo de oxígeno de una molécula de agua y el átomo de oxígeno de otra molécula de agua. (p. 44)

hidrólisis
Reacción que añade agua a través de un enlace covalente y rompe este enlace. La hidrólisis es la descomposición de moléculas grandes en otras más pequeñas. (p. 51)

hidrofílico
"Amante del agua", describe moléculas polares que se disuelven fácilmente en el agua. (p. 38)

hidrofóbico
"Temeroso del agua", describe moléculas que no se disuelven en el agua. (p. 38)

hipertónica
Describe una solución que tiene una mayor concentración de soluto (potencial hídrico) que otra. (p. 159)

hipótesis

explicativo
Explicativo o explicativo de una o más observaciones o hechos que se hacen predicciones que pueden ser comprobadas a partir de observaciones (p. 6)

hipotónica
Describe una solución hay que tiene una concentración de soluto más baja (p. 159) que la solución.

I

independiente variable
La variable que se manipula en un experimento para probar una hipótesis.

inhibidor
Compuesto que disminuye la actividad de una enzima. (p. 205)

comportamiento innato
Comportamiento que se manifiesta en organismos sin experiencia (p. 728) que exista una experiencia anterior.

integral membrana proteína
Proteína que está permanentemente asociada con la membrana celular y no puede separarse de la célula sin destruir la membrana misma. (p. 139)

interfase

interfase

Una de las dos fases principales del ciclo celular, en la cual la célula crece y sintetiza las proteínas y los ácidos nucleicos (p. 324)

intrón

Secuencia intermedia que se elimina del ARN durante el splicing (p. 465)

invasivas

Especies que se establecen en nuevos sistemas (p. 628)

ion

Átomo con carga eléctrica. (p. 31)

iónico

Enlace en el que dos iones con cargas eléctricas opuestas se asocian. (p. 34)

isotónico

Describe una solución que tiene la misma concentración de soluto (o potencial hídrico) que otra. (p. 159)

isótopo

Una de dos o más formas del mismo elemento con diferentes cantidades de neutrones. (p. 30)

K

kariotipo

Una de las dos fases principales del ciclo celular, en la cual la célula copia su ADN y sintetiza las proteínas y los ácidos nucleicos para la mitosis.

Secuencia intermedia que se elimina del ARN durante el splicing. (p. 465)

especies invasoras

Especies que se establecen en nuevos sistemas. (p. 628)

ion

Átomo con carga eléctrica. (p. 31)

enlace iónico

Enlace en el que dos iones con cargas eléctricas opuestas se asocian. (p. 34)

isotónico

Describe una solución que tiene la misma concentración de soluto (o potencial hídrico) que otra. (p. 159)

isótopo

Una de dos o más formas del mismo elemento con diferentes cantidades de neutrones. (p. 30)

Revised display of the pairs of chromosomes. (p. 352)

kaposi sarcoma

Vascular neoplasm that affects the mucosa of the oral cavity in which a disproportionate number of blood vessels are present. (p. 788)

kinase

An enzyme that catalyzes the transfer of a phosphate group from ATP to another molecule. (p. 293)

kinetic energy

Energy of motion. (p. 185)

kinetochore

The protein complex on a chromatid where the microtubules of the spindle attach. (p. 328)

Krebs cycle

The third stage of cellular respiration, in which acetyl-CoA is broken down and carbon dioxide is released; also called the citric acid cycle. (p. 237)

L

lagging strand

A daughter strand that is synthesized in short segments, in the direction opposite to the replication fork, because the parental double helix unwinds, a new DNA

Ejemplo de pares de cromosomas. (p. 352)

especies clave

Pueblos o plantas que afectan a otros organismos en una comunidad en una forma desproporcionada a su abundancia o biomasa.

quinasa

Enzima que catalizan la transferencia de un grupo fosfato del ATP a otra molécula.

energía cinética

Energía del movimiento. (p. 185)

cinetocoro

Complejo proteico en un cromátido donde se unen los husos mitóticos. (p. 328)

Ciclo de Krebs

Tercera etapa de la respiración celular, en la que el CoA se descompone y el dióxido de carbono se libera; también conocido como ciclo del ácido cítrico. (p. 237)

cadena retardada

Cadena de ADN que crece en la dirección 5′ a 5′ hacia la horquilla de replicación, en la que, según la doble hélice parental se va

piece is added, at intervals, a new fragmento de ADN a intervalos, y cada nuevo fragmento se alarga en su extremo 3′ hasta alcanzar al fragmento anterior.

piece is elongated at its 3′ end until it reaches the piece in front of it (p. 453)

ley de la segregación independiente

law of independent segregation

El principio de que la segregación de un par de genes es independiente de la segregación de otro par de genes.

The principle that the segregation of one set of alleles for one gene is independent of the segregation of another set of alleles for a different gene (p. 378)

ley de segregación

law of segregation

Principio según el cual los miembros de un par de genes se separan durante la meiosis.

The principle that the members of a pair of genes separate during meiosis (p. 370)

cadena líder

leading strand

Cada hebra recién sintetizada de ADN que crece hacia la horquilla de replicación, en la que la doble hélice parental se desenrolla, estando la síntesis de un nuevo polímero de ADN en curso (p. 453)

A newly synthesized strand of DNA that grows toward the replication fork, in which the parental double helix is being unwound, and on which a polymerase is actively synthesizing a new DNA polymer (p. 453)

aprendizaje

learning

Adquisición de información o de conocimiento por medio de la experiencia del individuo en su entorno; juega un papel

Acquisition of information or knowledge through an individual's experience in its environment; plays a large

importante (p. 728)

ligando

Molécula que se enlaza con una forma específica de otra molécula. (p. 212)

ligandos

Moléculas pequeñas que se unen a receptores celulares específicos y alteran la actividad de las proteínas receptoras. (p. 217)

ligasa

Enzima que une dos moléculas de ADN. (p. 398)

lípido

Un grupo de moléculas orgánicas que incluye grasas, aceites, ceras y esteroides. Los lípidos son hidrofóbicos y se disuelven en disolventes orgánicos como el éter y el cloroformo. (p. 133)

lípido de membrana

Lípido que forma parte de una membrana celular. Los lípidos de membrana son anfipáticos y están orientados hacia el medio acuoso, con sus colas hidrofóbicas apuntando hacia el interior de la bicapa lipídica. (p. 728)

lipoproteína

Proteína que contiene lípidos. (p. 728)

lipid

Tipo de molécula orgánica hidrofóbica: los lípidos, al ser menos polares, tienden a no mezclarse con el agua y forman una barrera entre la célula y su ambiente. (p. 38)

logistic growth model

Modelo que describe el crecimiento poblacional cuando la densidad de carga capacity. (p. 168)

lysosome

Vesícula derivada del aparato de Golgi that contiene enzymes que descomponen macromolécules such as proteínas, ácidos nucleicos, lípidos y carbohidratos. (p. 109)

M

M phase

Una de two fases principales del mitotic cell cycle, consistiendo en mitosis y cytokinesis. (p. 324)

material inheritance

Tipo de herencia en which the genes in the offspring derive from the mother. (p. 401)

matter

Material that constitutes objetos físicos. (p. 26)

máximo crecimiento poblacional (r_{max})

(r_{max})

The maximum growth rate possible for a population living without restrictions. (p. 758)

media

A measure of the average of a set of numbers. The median is determined by adding all the values and dividing by the number of values. (p. 20)

mediana

El número en medio de un conjunto de números ordenados de menor a mayor. (p. 20)

meiosis

A form of cell division in which a parent cell divides into four daughter cells. (p. 352)

La división celular en la que una célula madre se divide en cuatro células hijas.

meiosis I

The first step in meiosis, in which homologous chromosomes are separated from each other. (p. 353)

meiosis II

The second step in meiosis, in which sister chromatids are separated from each other. (p. 353)

messenger RNA (mRNA)

A RNA molecule that combines with a ribosome to direct the synthesis of proteins.

ARN mensajero (ARNm)

Molécula de ARN que se combina con un ribosoma para dirigir la síntesis de proteínas.

the genetic "message" from the DNA to the ribosome. (p. 463)

metabolic pathway

A series of chemical reactions that build up or break down molecules in a cell. (p. 186)

metabolic rate

The number of calories per unit of time an organism uses while at rest. (p. 738)

metabolism

The chemical reactions that occur within cells to convert energy into a form that cells can use and transfer energy in living organisms. (p. 96)

metaphase

The phase of mitosis in which the chromosomes are aligned near the center of the dividing cell. (p. 328)

migration

The movement of individuals from one population to another, resulting in a new population. (p. 604)

mitochondria (singular, mitochondrium)

Organelles specialized for the release of energy in eukaryotic cells, through the oxidation of organic compounds. (p. 110)

molecule

Two or more atoms held together by sharing electrons. (p. 46)

monosaccharide

A simple sugar such as glucose or fructose. (p. 50)

mutation

Any change in a gene or chromosome. (p. 304)

mutualism

A relationship between two species in which both benefit. (p. 622)

myelin sheath

A fatty insulating layer around the axon of a neuron that speeds the transmission of nerve impulses. (p. 1146)

myofibril

A bundle of contractile fibers in a muscle cell. (p. 1186)

myosin

A protein that forms the thick filaments in muscle cells. (p. 1186)

natural selection

The process by which organisms with traits that are well suited to their environment survive and reproduce more than other members of their species do. (p. 502)

nervous system

The network of specialized cells that transmits information throughout the body. (p. 1146)

neuron

A nerve cell. (p. 1146)

neurotransmitter

A chemical that carries a nerve impulse across a synapse. (p. 1150)

niche

The sum of all the ways in which a species lives and interacts with other species and with its environment. (p. 622)

nitrogen fixation

The process by which nitrogen gas is converted into ammonia. (p. 1000)

nitrogen-fixing bacteria

Bacteria that can convert nitrogen gas into ammonia. (p. 1000)

nitrogen-fixing plant

A plant that can convert nitrogen gas into ammonia. (p. 1000)

nitrogen mineralization

The process by which nitrogen in organic matter is converted into ammonium. (p. 1000)

nitrogen-rich fertilizer

Fertilizer that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic matter

Organic matter that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic material

Organic material that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic nutrient

Organic nutrient that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic substance

Organic substance that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic compound

Organic compound that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic molecule

Organic molecule that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic ion

Organic ion that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic atom

Organic atom that contains nitrogen in a form that plants can use. (p. 1000)

nitrogen-rich organic element

Organic element

mitochondrial matrix

The space enclosed by the inner membrane of the mitochondria. (p. 110)

mitosis

The stage of M phase that produces two idéntica nuclei in the eukaryotic cell cycle. (p. 324)

mitotic spindle

A structure in the cytosol made up predominantly of microtubules that pulls the chromosomes into separate daughter cells. (p. 326)

mode

The most common number in a set of numbers. (p. 21)

molarity

The ratio of solute in a volume of solution, expressed as moles of solute per liter of solution. Also called molar concentration. (p. 156)

molecular clock

The observation that the divergence between groups reflects the time since the common ancestor. (p. 618)

molécula

Sustancia química formada por dos o más átomos.

cruzamiento híbrido

Cruzamiento de dos individuos híbridos para un rasgo específico, que poseen dos alelos distintos.

monómero

Molécula única que puede unirse chemically with similar molecules to form a polímero.

homología

Estructura anatómica que es similar en dos grupos de organismos porque estaba presente en el ancestro común de los dos grupos y se retuvo a lo largo del tiempo. (p. 516)

regla de la multiplicación de la probabilidad

Regla que establece que la probabilidad de que dos acontecimientos independientes se produzcan es el producto de sus probabilidades individuales. (p. 372)

mutágeno

Agente que aumenta la probabilidad de mutación. (p. 520)

mutación

Cualquier cambio heredable en el material genético, generalmente en la secuencia de

secuencia de nucleótidos de un gen.

mutualismo

Tipo especial de simbiosis en la que ambas especies se benefician de la relación. (p. 305)

recombination

Recombinación. (p. 787)

N

natural selection

Mecanismo de evolución que se produce cuando hay variación genética en una población de organismos y las características más adecuadas para la supervivencia particular contribuyen proporcionalmente a la reproducción futura. Por lo tanto, la selección natural es el mecanismo de adaptación. (p. 3)

negative control

Véase **control negativo** (p. 8)

negative feedback

Patrón de respuesta en el que el output de a system de poner término al original, directing instead ésta, lo que da lugar a estabilidad (p. 285) estables u homeostasis.

negative regulatory mutation

Mutación que, por ejemplo, impide que se lee DNA at a DNA near the gene to prevent

negative

Molécula que reprime la transcripción para

transcriptions (p. 486)

neutrón

Partícula atómica del núcleo que no lleva carga. (p. 30)

Atomic particle that does not carry a charge.

nicho

Descripción completa del papel que una especie ocupa en su ambiente y de sus requisitos, recursos, como abióticos.

A complete description of the role a species plays in its environment and of its requirements, such as abiotic and biotic. (p. 665)

nicotinamida adenina dinucleótido fosfato (NADPH)

Portador de electrones en muchas reacciones bioquímicas, es el agente reductor utilizado en el ciclo de Calvin durante la fotosíntesis. (p. 214)

nitrogenada

Compuesto que contiene nitrógeno y que forma parte de un nucleótido. (p. 78)

A compound that contains nitrogen that makes up part of a nucleotide.

nodo

En un árbol filogenético, el punto en donde se divide una línea, representa el ancestro común del que vienen las especies divergentes. (p. 564)

In a phylogenetic tree, the point where one lineage splits, represents the common ancestor from which the descendant species diverged.

nodos cromosómicos

Cromátidas que están conectadas por un centrómero. (p. 354)

Chromatids that are connected by a centromere.

nondisjunción

Falla de la separación de un par de cromosomas

The failure of a pair of chromosomes to separate

durante la fase de división. (p. 123)

enlace covalente polar

Enlace que se produce cuando los electrones se comparten por igual, es decir, cuando los átomos.

apareamiento aleatorio

Selección de pareja que no es al azar, sino que se basa en el genotipo o el fenotipo. (p. 606)

cadena molde

Cadena de ADN que se utiliza como plantilla, o modelo, para la síntesis de ARN durante la transcripción. El polímero de ARN es el reverso complementario de la cadena molde. También se denomina cadena codificante, cadena sentido y cadena positiva. (p. 460)

distribución normal

Distribución simétrica en la cual la mayoría de los valores se agrupan en torno a la media, y los valores se alejan de la media. En una distribución normal, aproximadamente el 68% de los valores se encuentran dentro de una desviación estándar de la media, el 95% dentro de dos desviaciones estándar y el 99,7% dentro de tres desviaciones estándar. (p. 21)

envoltura nuclear

Las dos membranas, interna y externa, que

define the limit of the nucleus. (p. 106)

ácido nucleico

A type of organic molecule that stores and transmits genetic information. (p. 38)

nucleótido

A subunit of nucleic acids, consisting of a 5-carbon sugar, a nitrogenous base, and one or more phosphate groups. (p. 38)

núcleo

The dense, central part of an atom. (p. 30)

núcleo (de una célula)

The compartment of the cell that houses the DNA in chromosomes. (p. 98)

hipótesis

A hypothesis predicts the variable experimentalmente controlado experimentalmente, y el efecto, diferencia entre los datos recogidos de los grupos de control y los grupos experimentales se debe al azar. (p. 11)

O

observación

Acto de ver y notar cosas. (p. 5)

operón

Grupo de genes funcionalmente relacionados, situados en un segmento de ADN a lado de ADN a

single-celled

Refiere a un ser vivo formado por una sola unidad procariota. (p. 178)

orgánelo

Cualquier de los diversos compartimentos de una célula eucariota que dividen el contenido de la célula en espacios especializados para funciones específicas. (p. 101)

orgánico

Compuesto químico que contiene carbono. (p. 26)

organismo

Ser individual vivo que muestra las propiedades de la vida. (p. 1)

osmorregulación

La regulación de niveles de agua y solutos para controlar la presión osmótica. (p. 163)

ósmosis

El movimiento de un solvente, como agua, a través de una membrana semipermeable hacia el lado de mayor concentración de soluto. (p. 156)

presión osmótica

La presión necesaria para evitar que el agua pase de una solución a otra por ósmosis. (p. 157)

grupo externo

Grupo de organismos que tienen un ancestro

común más antiguo que tiene un ancestro común del grupo de interés y que, por lo tanto, sirve de referencia para las evaluaciones evolutivas dentro del grupo de interés. (p. 654)

oxidación

Reacción química en la que una molécula pierde electrones y energía. (p. 214)

fosforilación oxidativa

Conjunto de reacciones químicas por las que pasan electrones a lo largo de una cadena de transporte de electrones hasta el aceptor final de electrones, el oxígeno, y se sintetiza ATP. (p. 236)

P

parasitismo

Interacción en la que una especie vive dentro o encima de otro organismo, llamado huésped. (p. 785)

pasivo

Movimiento de moléculas a través de una membrana por difusión. (p. 146)

patrón de herencia

Tipo de herencia en el cual los genes en las mitocondrias o los cloroplastos se heredan de la madre del individuo.

father. (p. 401)

pedigree

Representación gráfica de un árbol genealógico. (p. 380)

peptide bond

The bond between the carboxyl end of an amino acid and the amino end of another amino acid that creates a peptide. (p. 69)

péptido

Molécula formada por la unión de dos o más aminoácidos. Los péptidos tienen dos extremos, uno con un grupo amino libre y otro con un grupo carboxilo libre. Los péptidos pueden estar formados por decenas o incluso cientos de ellos. (p. 69)

per capita growth rate (*r*)

Tasa de crecimiento de la población dividida por el tamaño de la población. (p. 756)

periodic table of the elements

Tabla en la que los elementos están indicados por sus símbolos químicos y ordenados por orden creciente de su número atómico. (p. 31)

peripheral membrane protein

Proteína que está asociada con la bicapa lipídica a través de interacciones débiles no covalentes. (p. 139)

pH scale

Escala de pH

Medida de la acidez o alcalinidad de una solución. La escala pH va de 0 a 14 y se calcula mediante el logaritmo negativo de la concentración de iones de hidrógeno. (p. 49)

pH

Medida de la acidez o alcalinidad de una solución. La escala pH va de 0 a 14 y se calcula mediante el logaritmo negativo de la concentración de iones de hidrógeno. (p. 49)

phenotype

The set of traits that an organism expresses, such as hair color or eye color. (p. 350)

fenotipo

Conjunto de rasgos que un organismo expresa, como el color de ojos o cabello.

phenotypic plasticity

The ability of a single genotype to produce different phenotypes in different environments. (p. 406)

plasticidad fenotípica

La capacidad de un solo genotipo de producir distintos fenotipos en ambientes distintos.

phospholipid

A type of lipid and a major component of the cell membrane. (p. 61)

fosfolípido

Tipo de lípido que actúa como componente de la membrana celular.

photophosphorylation

The process by which energy from sunlight drives the movement of electrons along a chain of transport proteins, which leads to the synthesis of ATP. (p. 236)

fotofosforilación

Proceso por el cual la energía de la luz solar impulsa el movimiento de electrones a lo largo de una cadena de transporte, lo cual conduce a la síntesis de ATP.

photosynthesis

The biochemical process in which the energy of sunlight is used to synthesize carbohydrates from carbon dioxide and water. (p. 111)

fotosíntesis

Proceso bioquímico en el que se utiliza la luz solar para sintetizar carbohydrates a partir de dióxido de carbono y agua.

photosynthetic electron transport chain

A series of redox reactions in which light

cadena fotosintética de transporte de electrones

Serie de reacciones redox en las que la energía de la luz absorbida por la clorofila se utiliza para impulsar el movimiento de electrones en la fotosíntesis oxigénica, los electrones provienen del agua, y el aceptor terminal de electrones es el NADP + NADP^+. (p. 217)

fotosistema

Complejo proteína-pigmento que absorbe la energía de la luz para impulsar los electrones a lo largo de una cadena de transporte de electrones. (p. 224)

filogenético

Relativo a la filogenia o a la historia evolutiva de un grupo de organismos. (p. 563)

filogenia

La historia de descendencia con modificación y la ramificación y la diversificación a lo largo del tiempo. (p. 645)

plasmalema

Ver **membrana celular**.

plásmido

En bacterias, una pequeña molécula de DNA circular de ADN que lleva genes que dan ventajas selectivas y que se replica independientemente del DNA del cromosoma bacteriano.

plasmid

Un ADN circular de una célula bacteria. (p. 442)

plasmodesmata

Conexiones entre las células vegetales que permiten que pasen las moléculas y las substancias directamente de citoplasma de una célula a otra. (p. 282)

polar (molécula)

Molécula que tiene regiones de carga positiva y negativa. (p. 43)

polar covalent bond

Enlace que resulta cuando los electrones son compartidos desigualmente entre dos átomos. (p. 34)

polarity

See **directionality** (p. 80)

poly(A) tail

Los nucleótidos de adenina (A) que se añaden al extremo 3′ de un transcripto primario. (p. 465)

polymer

Molécula grande compuesta por muchas subunidades más pequeñas. (p. 37)

polymerase chain reaction (PCR)

Método selectivo y altamente sensible para hacer copias de un fragmento de ADN, que permite la región de ADN a ser determinada

replicación de ADN y copia es decir, (p. 526)

polipéptido

Polímero de aminoácidos unidos por enlaces peptídicos. (p. 69)

poliploidía

Condición de tener más de dos series completas de cromosomas en el genoma. (p. 517)

polisacárido

Polímero de azúcares simples. Polysaccharides proveídos por energía a largo plazo o soporte estructural. (p. 57)

población

Todos los individuos de una especie que viven en un área particular, de entre los varios grupos de organismos de la misma especie que viven en la misma área geográfica. (p. 276)

positivo

Un sujeto o grupo que recibe un tratamiento o variable con un efecto conocido en un experimento controlado y que, por tanto, se espera que muestre un cambio predecible. (p. 8)

retroalimentación positiva

Patrón de respuesta en el cual la salida o se

respuesta de estímulo

Cualquier cambio en el sistema nervioso que produce una actividad en el mismo sistema como respuesta a un estímulo. (p. 285)

positive regulatory protein

Any protein, such as a transcription factor, that binds to DNA and increases the rate at which transcription can take place. (p. 484)

proteína reguladora positiva

Cualquier molécula (por ejemplo, un factor de transcripción) que se une al ADN de tal manera que se pueda producir la transcripción.

postzygotic

Describes factors that prevent the fertilized egg from developing into a fertile individual. (p. 166)

postcigótico

Describe factores que impiden que el huevo fecundado se convierta en un individuo fértil.

potential energy

Energy a body has because of its structure or position. (p. 185)

energía potencial

Energía almacenada en la estructura o posición de un objeto.

pressure potential

The effect of pressure on the movement of water. (p. 160)

potencial de presión

El efecto de la presión en el movimiento del agua.

prezygotic

Describes factors that prevent the fertilization of an egg. (p. 166)

prezigótico

Describe factores que previenen la fertilización de un óvulo.

predation

An interaction that involves one species killing and consuming another. (p. 784)

predación

Interacción que involucra una especie matando y consumiendo a otra.

primary active transport

Active transport that uses the energy of ATP

transporte activo primario

Transporte activo que utiliza la energía de ATP

energy. (p. 148)

primary structure

The sequence of amino acids in a péptido or a proteína. (p. 70)

primer transcript

The initial RNA molecule that is synthesized from a template DNA strand. (p. 463)

primer

A short strand of DNA or ARNe in DNA replication, el ARN se utiliza como primer for DNA synthesis. (p. 451). También se conoce como partidor, iniciador, o *primer*.

probability

The likelihood of an event happening. (p. 372) un acontecimiento.

producto

Átomos o moléculas que se producen en una reacción química. (p. 35)

prokaryotic

Describe una célula que no tiene núcleo; usualmente colectivo para bacterias y archaea. (p. 98)

prometaphase

The phase of mitosis in which the nuclear envelope breaks down and the tubulos del huso mitótico se pueden adjuntar a los cromosomas. (p.

328)

promotor

Región reguladora donde RNA polimerasa y otras proteínas se unen a la molécula de ADN en el proceso de transcripción. (p. 461)

promoter

A regulatory region where RNA polymerase and associated proteins bind to the DNA molecule in the process of transcription. (p. 461)

corrección de errores

Proceso en el cual DNA polimerasa del ADN puede corregir mismatches by excising and replacing a mismatched base. (p. 455)

proofreading

The process in which DNA polymerase can correct its own errors by excising and replacing a mismatched base. (p. 455) que no corresponde.

profase

Fase de mitosis en la cual los cromosomas se hacen visibles bajo un microscopio. (p. 326)

prophase

The phase of mitosis in which the chromosomes become visible through the microscope. (p. 326)

proteína

Tipo de molécula orgánica que provee soporte estructural a la célula y realiza una variedad de funciones químicas. (p. 37)

protón

Partícula pequeña del núcleo que lleva una carga positiva. (p. 30)

equilibrio puntuado

La idea de que las especies pasan por períodos de relativa inactividad, cambios, interrumpidos por rápidos períodos de cambio

punctuated equilibrium

The idea that species go through periods of relatively little change, which are interrupted by short periods of rapid change and

rápida diversificación. (p. 76)

purina

En los ácidos nucleicos, dos de las bases adenina y guanina, que tienen una estructura de doble anillo. (p. 78)

pirimidina

En los ácidos nucleicos, las bases timina, citosina y uracilo, que tienen una estructura de anillo único. (p. 79)

Q

quaternary structure

Nivel de la estructura proteica que surge de la interacción de dos o más cadenas polypeptide chains or polipeptídicas, each with its own tertiary structure. (p. 72)

quorum sensing

Densidad de moléculas señalizadas, dependiente de la cantidad de población celular, las cual es bien conocido en DNA respuestas. (p. 78)

R

radiocarbon dating

Datación de materiales usando el decay of radioisotopes as a clock, including the decay of radiocarbon ^{14}C. (p. 14)

radiométrica datación

Datación de materiales usando el decay of radioisotopes as a clock, including the decay of radiocarbon ^{14}C.

radiactivo al nitrógeno puede ofrecer datos de hasta unos cientos de miles de años, y los isótopos radiactivos de uranio y plomo se utilizan para medir la mayor parte de la historia de la Tierra. (p. 624)

rango

Medida de la dispersión de los números en un conjunto de cifras. El rango se calcula determinando la diferencia entre el número más alto y el más bajo de un conjunto de números. (p. 22)

reactivo

Átomos o moléculas que se combinan en una reacción química. (p. 35)

reacción de reducción

Molécula con forma especial en la que se fija una energía de un electrón en transporte. (p. 223)

receptor

Molécula que se une a una señal de otra célula y responde a ella. (p. 138)

receptor-quinasa

Proteína receptora de la membrana celular que tiene una actividad tirosina quinasa

ligandos

Moléculas que se unen a receptores celulares. (p. 29)

señalización extracelular

Proceso de comunicación entre células mediante la liberación de una molécula señal al espacio extracelular.

recesivo

Describe un rasgo o alelo que solo se expresa en homozigosis, es decir, cuando dos copias idénticas del gen están presentes. Los alelos recesivos pueden estar presentes pero no expresarse en el fenotipo. (p. 369)

recombinación

Véase **entrecruzamiento cromosómico.**

reducción

Reacción química en la cual una molécula gana electrones y energía. (p. 214)

replicación

Proceso por el cual se duplica la doble hélice de ADN. (p. 448)

replicación de ADN

Proceso en el que se separan las cadenas de ADN parentales y se forman dos dobles hélices de ADN.

transcriptasa inversa

Enzima que utiliza un ARN como molde para sintetizar una cadena de ADN que es complementaria en secuencia al ARN. (p. 544)

ácido ribonucleico (ARN)

Molécula de cadena simple que transfiere información del ADN a otras partes de la célula y participa en la síntesis de proteínas. Existen varios tipos de ARN, incluyendo el ARN mensajero (ARNm), el ARN de transferencia (ARNt) y el ARN ribosómico (ARNr), cada uno con funciones específicas en el proceso de síntesis proteica. (p. 19)

proteínas, (p. 38) otras funciones.

ribosa

Azúcar pentosa que se encuentra en el ARN (p. 56)

ribosomal RNA (rRNA)

ARN codificado por genes del cromosoma 13 que se encuentra en los ribosomas (p. 465)

ribosoma

Estructura compleja de ARN y proteínas que sintetiza las proteínas a partir del ARN (p. 96).

RNA polymerase

Enzyme that synthesizes an RNA transcript from a DNA template (p. 460)

procesamiento del ARN

Modificación que convierte el primary transcript en ARN maduro, enabling the RNA molecule to be exported to the cytoplasm and recognized by the translational machinery (p. 463)

RNA splicing

Proceso por el cual los exones son unidos y los intrones son eliminados del primary transcript. (p. 465)

RNA world hypothesis

La idea de que las primeras células dependían del ARN tanto para almacenar información como para la catálisis.

raíz

Base de un árbol filogenético, que representa el ancestro común más reciente de todos los organismos en el árbol. (p. 564)

S

fase S

Fase de la interfase en la que la célula copia su ADN. La fase S sigue a la G_1 y precede a la G_2. (p. 325)

saturado

Describe a ácidos grasos que no contienen dobles enlaces, lo que significa que el máximo número de átomos de hidrógeno está unido a cada átomo de carbono, "saturándolos" con hidrógeno. (p. 58)

investigación científica

Forma de aprender sobre el mundo natural; proceso utilizado para estimular preguntas y buscar respuestas sobre el mundo natural de una manera ordenada. (p. 5)

segunda ley de la termodinámica

Principio según el cual la transformación de la energía está asociada con un aumento del grado de desorden en el universo. (p. 189)

segundo mensajero

signal molecule

Molécula señalizadora

Molecule that amplifies a response within a cell (p. 293)

Una molécula que amplifica una respuesta dentro de la célula.

secondary active transport

transporte activo secundario

Transporte activo que utiliza la energía de un gradiente electroquímico para impulsar el movimiento de las moléculas. (p. 148)

secondary structure

estructura secundaria

The structure that results from hydrogen bonding in the polypeptide backbone. Two kinds of secondary structures are the alpha helix (α-helix) and the beta sheet (β-sheet). (p. 70)

La estructura resultante del enlace de hidrógeno en el polipéptido esqueleto. Dos tipos de estructuras secundarias son la hélice alfa (α-hélice) y la hoja beta (β-hoja).

selective pressure

presión selectiva

The full set of environmental conditions, both abiotic and biotic, that influence the evolution of a population by natural selection. (p. 576)

Conjunto completo de condiciones, tanto abióticas como bióticas, que influyen en la evolución de una población por selección natural.

replication

replicación del ADN

The mechanism of DNA replication in which each strand of a parent DNA molecule serves as a template for the synthesis of a new daughter strand. (p. 448)

Mecanismo de la replicación del ADN en el cual cada cadena de una molécula de ADN sirve como molde para la síntesis de una nueva cadena hija.

sensor

In homeostasis, the component that detects a stimulus. (p. 284)

En la homeostasis, el componente que detecta un estímulo.

set point

punto de ajuste

homeostasis

En la homeostasis, el valor fisiológico típico de un parámetro corporal, como la temperatura corporal o los niveles de glucosa en la sangre, es activamente mantenido por el cuerpo dentro de un rango muy pequeño de fluctuación. (p. 284)

sexo cromosómico

Cromosomas asociados con la determinación del sexo. (p. 352)

sexo-ligado

Genes que están ubicados en uno de los dos cromosomas sexuales. (p. 394)

sexual reproducción

Proceso por el cual un individuo recibe material genético de dos padres; en organismos sexuales, el proceso incluye la producción de gametos y la fecundación. (p. 351)

selección sexual

Forma de selección que promueve rasgos que aumentan la capacidad de un individuo para atraer a una pareja. (p. 582)

carácter compartido

Carácter o rasgo que está presente en dos o más grupos de organismos. (p. 651)

transducción de señal

Proceso por el cual una señal externa se

convierte en un antepasado interno (p. 290)

signal transduction

A series of chemical reactions inside a cell that initially signal and eventually amplify a process in the cell. (p. 294)

señalización

Serie de reacciones químicas dentro de una célula que inicia la señal y la amplifica para que la célula responda. (p. 294)

signaling molecule

A chemical messenger that functions in the cell or in nearby cells by affecting activities of other cells. (p. 277)

señalizadora

Mensajero químico que actúa en la comunicación celular o en una célula afectando actividades de otras células. (p. 277)

Simpson's diversity index

An equation that quantifies diversity of species in a community. (p. 779)

índice de diversidad de Simpson

Ecuación que cuantifica la diversidad de especies en una comunidad. (p. 779)

single bond

A covalent bond in which two atoms share two electrons. (p. 33)

enlace simple

Enlace covalente en el cual dos átomos comparten dos electrones.

sister chromatids

The two copies of a chromosome resulting from DNA duplication that remain connected at the centromere. (p. 325)

cromátidas hermanas

Las dos copias de un cromosoma resultantes de la duplicación del ADN que permanecen unidas en el centrómero. (p. 325)

solute

A dissolved molecule or ion, such as sugar, amino acids, and salts, that is found in a solvent such as water. (p. 156)

soluto

Molécula disuelta, como azúcares, aminoácidos, y sales que se encuentran en un solvente como el agua. (p. 156)

solute potential

The effect of solutes on the movement of

potencial de soluto

Efecto de los solutos en el movimiento del

water. (p. 160)

solvente

A substance that can dissolve another substance. (p. 48)

especiación

The process whereby new species are created. (p. 668)

especie

A group of individuals that are capable of producing viable, fertile offspring. (p. 2)

calor específico

The amount of heat required per unit mass of a substance to raise its temperature 1 degree Celsius (p. 46)

desviación estándar

Medida de la dispersión de los números en un conjunto de datos. La desviación estándar se calcula como la raíz cuadrada de la varianza, o la media de los cuadrados de las diferencias con la media. (p. 22)

standard error of the mean

Medida de la distancia entre la media de la muestra y la media de la población. El error estándar de la media se calculated

by dividing the variance by the square root of the number of values in a sample. (p. 24)

steroid

A type of lipid, the molecular precursor of cholesterol and steroid hormones. (p. 60)

stoma

A region of chloroplasts or leaves in which the thylakoids, the thylakoid membrane and the Calvin cycle takes place. (p. 218)

substrate-level phosphorylation

A way of generating ATP in which a phosphate group is transferred from a molecule to ADP. (p. 235)

substrate (*S*)

(*S*) Molécula sobre la que actúa un enzima; también llamada reactante. (p. 200)

superficie

Área total de la superficie exterior de un objeto. (p. 105)

tensión superficial

Medida de la dificultad de romper la superficie de un líquido. (p. 44)

symbiosis (plural, symbioses)

Interacción estrecha que ha evolucionado entre

especies

Especies que viven juntas, suelen ser interdependientes. (p. 172)

simpátricas

Describe poblaciones que están en la misma área geográfica. (p. 673)

sistema

Conjunto de entidades que funcionan juntas. Un sistema puede ser no vivo o vivo. (p. 4)

T

célula objetivo

Célula que tiene receptores proteicos que pueden unirse a una molécula específica. (p. 271)

telofase

Fase de la mitosis en la que se forman los núcleos de las células hijas y los cromosomas se desenrollan para volver a su estado original. (p. 328)

cadena molde

Cadena de ADN que se usa como molde, o modelo, para sintetizar ARN durante la transcripción. La cadena molde se llama también cadena plantilla, cadena minus o cadena antisentido. (p. 460)

estructura terciaria

estructura terciaria

three-dimensional shape of a single polypeptide chain, usually made up of several secondary structure elements (p. 71)

La forma tridimensional de una cadena polipeptídica, generalmente formada por varios elementos de estructura secundaria.

test group

The group that is exposed to the independent variable in an experiment. Also known as the **experimental group.** (p. 7)

Grupo de prueba

El grupo que se expone a la variable independiente en un experimento. También se conoce como **grupo experimental.**

theory

A general explanation of the world supported by a large body of experiments and observations. (p. 13)

Una explicación general del mundo respaldada por un gran número de experimentos y observaciones.

thylakoid

A flattened sac within the chloroplast, bounded by membranes, where the light-dependent reactions of photosynthesis occur (p. 110)

Saco aplanado dentro del cloroplasto, que está delimitado por membranas, donde ocurren las reacciones fotosintéticas que dependen de la luz.

thymine (T)

A pyrimidine base. (p. 79)

Una base pirimidínica.

tonicity

A measure of osmotic pressure; the higher the solute concentration, the higher the tonicity. (p. 158)

Medida de la presión osmótica; cuanto mayor es la concentración de soluto, mayor es la tonicidad.

topoisomerase

An enzyme that relaxes tension in the DNA helix during replication. (p. 79)

Enzima que alivia la tensión en la hélice del ADN durante la replicación del ADN.

transcription. (p. 451)

factor de transcripción

Proteína que se une al promotor de un gen para iniciar la transcripción.

transcripción

Síntesis de ARN a partir de un molde de ADN. (p. 440)

transducción

Transferencia de ADN de célula a célula por medio de un virus; forma de transferencia horizontal. (p. 521)

ARN de transferencia (ARNt)

ARN codificante que transporta individual amino ácidos específicos para uso en la traducción.

transformación

Conversión de células de una cepa a otra, como, por ejemplo, cuando el ADN liberado al medio ambiente por la ruptura de las células es absorbido por las células receptoras. En tecnología de ADN recombinante, DNA introducido en una célula receptora. La transformación es una forma de transferencia

factor de transcripción

Proteína que se une al promotor de un gen para iniciar la transcripción.

transcripción

Síntesis de ARN a partir de un molde de ADN. (p. 440)

transducción

Transferencia de ADN de célula a célula por medio de un virus; forma de transferencia horizontal. (p. 521)

ARN de transferencia (ARNt)

ARN codificante que transporta individual amino ácidos específicos para uso en la traducción.

transformación

Conversión de células de una cepa a otra, como, por ejemplo, cuando el ADN liberado al medio ambiente por la ruptura de las células es absorbido por las células receptoras. En tecnología de ADN recombinante, DNA introducido en una célula receptora. La transformación es una forma de transferencia

genética horizontal.

estado de transición

Momento breve de una reacción química en el que se rompen los enlaces químicos de los reactivos y se forman los enlaces del producto. (p. 198)

elongación de la traducción

Proceso en el cual aminoácidos se añaden uno a uno a una cadena polipeptídica en el orden indicado por la secuencia de ADN. (p. 475)

traducción

Síntesis de una cadena polipeptídica correspondiente a la secuencia específica presente en una molécula de ARN mensajero. (p. 440)

iniciación de la traducción

Proceso en el cual comienza la traducción. Durante la iniciación, el codón AUG inicia la síntesis de la cadena polipeptídica. (p. 475)

translocación de la traducción

Proceso en el cual el ARNt y el aminoácido se desplazan del sitio A al sitio P del ribosoma. (p. 475)

proteína transmembrana

Proteína que se halla en la membrana

Proteína que atraviesa toda la bicapa lipídica; La mayoría de las proteínas integrales de membrana son proteínas transmembrana. (p. 139)

proteína transportadora

Proteína de membrana que mueve moléculas a través de la membrana celular. (p. 138)

transposición

Proceso en el cual una secuencia de ADN se mueve de una ubicación otra en una molécula de ADN. (p. 515)

triacilglicerol

Lípido compuesto por glicerol unido a tres ácidos grasos.

triploidía

Condición en la cual tres **completos** sets of chromosomes in the genome. (p. 517)

trophic cascade

Effects indirect effects caused by the presence of a predator. (p. 789)

niveles tróficos

Posición en la producción y consumo en niveles sucesivos que representan the movement of energy. (p. 741)

turgor pressure

Presión within cell resulting from the movement of water into the cell by osmosis. (p.

osis. (p. 114)

Turner, síndrome de

Condición en la que las hembras tienen solo un cromosoma *X*. (p. 426)

U

insaturado

Describe los ácidos grasos que contienen dobles enlaces. (p. 59)

uracilo (U)

Una base nitrogenada del ARN, que sustituye a la timina que se encuentra en el ADN. (p. 84)

V

vacuola

Orgánulo de almacenamiento presente en algunas células, particularmente en las vegetales, y también en algunos protistas, que contiene líquido, nutrientes, sustancias de desecho, y ayuda a controlar la presión del agua. (p. 114)

electrón de valencia

Electrón del nivel energético más externo de un átomo. (p. 31)

fuerzas de Van der Waals

Interacción de moléculas polarizadas debido a la atracción de cargas opuestas. (p. 59)

vesícula

transport

Respect for members of a club that transports students to a club trip. (p. 105)

vestigial structure

A structure that has lost its original function over time and is now very reduced in size. (p. 619)

virus

A microscopic agent that contains nucleic acid and a protein coat but cannot reproduce on its own. (p. 541)

visible light

The portion of the electromagnetic spectrum that we can see with our eyes. (p. 221)

volumen

The amount of space an object occupies. (p. 120)

W

water potential

A parameter that combines all the physical and chemical factors that influence the movement of water, such as pressure, osmosis, and gravity; a measure of the tendency of water to move from one region to another. (p. 157)

potencial hídrico

Parámetro que combina todos los factores físicos y químicos que influyen en el movimiento del agua, como la presión, la ósmosis y la gravedad; mide la tendencia del agua a pasar de una región a otra. (p. 157)

Z

zigote

Célula diploide formada por la fusión de dos gametos. (p. 360)

Answers to Concept Check and Review Questions

Module 0

✓ Concept Check 0.1

1. A comparison of a fire ant with an army ant will note the unity of life because both groups have the same general segmented body plan. It will also show the diversity of life because

the mandibles, abdomens, and heads of the two groups vary significantly in their structures and sizes.

2. A lack of energy would result in an organism being unable to carry out its cellular functions, maintain itself, grow, and reproduce, which would eventually cause death.

3. Without being able to retrieve information contained in their genes, organisms would be unable to respond to environmental changes and could not perform functions such as growth and reproduction.

4. The Canada lynx, using the systems of its eyes, nose, brain, nerves, bones, and muscles, is able to note the

presence of the snowshoe hare, close in on the hare, and give chase that may result in the capture of the hare. This would not be possible without the interaction of these systems.

✓ Concept Check 0.2

5. A scientist uses observation to propose a testable explanation of how, or why, the observation occurs. This is the hypothesis. The scientist investigates the hypothesis either by conducting further observations or through experimental investigation, or both.

6. An experimental group is one in which an independent variable is changed to determine if the

dependent variable changes because of it. A control group doesn't change the independent variable, and whether the dependent variable changes or not is also observed. It is important to have both a control and an experimental group if the researcher is to determine that changing the independent variable does change the dependent variable.

7. A guess is a hunch about something, while a hypothesis is a tentative explanation as to why an observation occurred. A theory, in a scientific sense, is a set of hypotheses about a particular natural phenomenon that has gained considerable scientific support via observation or experimental

examination.

Review Questions

1. B

2. C

3. B

4. D

5. A

6. D

7. C

Module 1

✓ Concept Check 1.1

1. Matter cycles within living systems and the environment. This means that matter is reused over and over again. By contrast, energy is not reused. Instead, energy flows through living systems and an input of energy is constantly required to sustain life.

2. The energy input for most habitats on Earth comes from the sun. Plants and other organisms convert energy from the sun into chemical energy in the form of carbon-rich organic molecules. Other organisms eat these carbon-rich organic molecules for sources of both matter and energy to survive, grow, reproduce and so on. As a result, the movements of carbon and energy are intimately related.

✓ Concept Check 1.2

3. An atom's components are the protons and neutrons of its nucleus and the electrons that travel around the central nucleus.

4. The periodic table is organized in rows and columns. Rows consist of elements with increasing numbers of protons and electrons in each successive element until the end of the row, where the outermost level is now complete with electrons. Vertical columns define elements with similar chemical properties, and which have the same number of electrons in their outermost level.

5. 14 N ^{14}N means that the atomic

mass of the element is 14, while 15 N ^{15}N means that it has a mass of 15. This is because 14 N ^{14}N and 15 N ^{15}N have seven protons in their nuclei, but 14 N ^{14}N has seven neutrons and 15 N ^{15}N has eight neutrons in its nucleus.

6. Four more electrons would bring carbon to eight electrons in its outer level, which would make the level complete.

7. Electrons furthest from the nucleus have the most energy, while those closest have the least amount of energy.

✓ Concept Check 1.3

8. A covalent bond is formed when electrons from two different atoms are shared in the outermost shells of each atom. A polar covalent bond occurs when the shared electrons are not shared equally and one atom more often has the electrons nearer to itself than does the other atom. In nonpolar covalent bonds, electrons are shared equally by the atoms. In an ionic bond, two ions with opposite electrical charges attract each other because of the differences in charge.

9. Due to its polarity, water is attracted to the positive and negative ions of sodium chloride. When water's slightly positive H atoms are close to the Cl $-$ Cl^-, and its slightly negative O atom is close to the Na $+$

Na^+ of the NaCl crystal, the water eventually surrounds the ions and dissolves them into the water itself.

10. The reactants are the three H 2 H_2 and one N 2 N_2 molecules, and the product is the two NH 3 NH_3 molecules.

✓ Concept Check 1.4

11. The four most common atoms in organic molecules are carbon, hydrogen, oxygen, and nitrogen.

12. Carbon requires four electrons to fill its outer shell, which allows it to form covalent bonds with four other atoms. As a result, carbon-based molecules are very diverse.

13. The four major types of organic molecules are proteins, nucleic acids, carbohydrates, and lipids.

14. A polymer is a molecule built of many small, repeating subunits.

15. Lipids, being hydrophobic, associate with each other and not water, so provide a barrier between the inside and outside of a cell, which is water based.

Review Questions

1. B

2. C

3. A

4. D

5. C

6. C

7. B

Module 2

✓ Concept Check 2.1

1. Water is a polar molecule; its hydrogen atoms are partially positive and its oxygen atom is partially negative. This polarity makes hydrogen bonding possible because the partially negative oxygen atom is attracted to the partially positive hydrogen atom of another water molecule.

2. Water's hydrogen bonding gives

water many of its characteristics, such as cohesion, adhesion, surface tension, and high specific heat.

✓ Concept Check 2.2

3. Due to its hydrogen bonds, water can surround an ammonia molecule and separate it from other ammonia molecules. Once the ammonia molecule is completely surrounded by water, it is dissolved.

4. The hydrogen atom of water binds to the nitrogen atom of ammonia, and the oxygen atom of water binds to the hydrogen atom of ammonia.

5. It is slightly basic because it has a higher value than 7.0, which means

that it has fewer H^+ than OH^- ions.

6. Because the pH scale is logarithmic and there is one unit of difference between the two solutions, the first solution contains 10 times as many H^+ ions as does the second solution.

✓ Concept Check 2.3

7. A dehydration synthesis reaction removes a water molecule from two reactants, and in the process joins them by a covalent bond.

8. A hydrolysis reaction uses water to break a covalent bond between two units of a molecule to make it into

smaller, simpler molecules.

9. Dehydration synthesis reactions build the large molecules and polymers that cells require to survive and function. Hydrolysis reactions break down large molecules so that the simple molecules they release may be taken up and used.

Review Questions

1. A

2. C

3. A

4. D

5. B

6. D

7. D

Module 3

✓ Concept Check 3.1

1. All carbohydrates include the elements carbon, hydrogen, and oxygen.

2. Monosaccharides can take on a linear or ring form.

3. In ring-structured monosaccharides, the atoms and groups attached to the ring are located either above or below the plane of the ring.

✓ Concept Check 3.2

4. A glycosidic bond is the covalent bond that links one monosaccharide to another or to a polymer of carbohydrates. It is formed by a dehydration synthesis reaction.

5. Both starch and cellulose are polysaccharides. Starch is an energy-storage molecule, while cellulose is a structural molecule that makes up the cell wall of plants.

✓ Concept Check 3.3

6. All lipids are hydrophobic and therefore do not dissolve well in water.

7. The components of triacylglycerol

are a glycerol molecule and three fatty acids.

8. Unsaturation can introduce a kink or bend in the fatty acid, making it lose its linear shape.

9. Three types of lipids are triacylglycerols, steroids, and phospholipids. Triacylglycerols store energy; steroids are components of cell membranes and act as chemical messengers; and phospholipids are the major components of cell membranes.

Review Questions

1. C

2. C

3. D

4. D

5. A

6. B

7. A

Module 4

✓ Concept Check 4.1

1. The R group or side chain of an amino acid gives a particular amino acid its unique properties because it is what is different among the various amino acids.

2. All amino acids have a central α

carbon attached to an amino group, a carboxylic acid group, an H atom, and a variable R group.

3. The groups of amino acids are hydrophobic, hydrophilic, and special amino acids. Hydrophilic amino acids may be polar but uncharged, acidic, or basic.

✓ Concept Check 4.2

4. A peptide bond connects amino acids in a protein.

5. A peptide bond occurs between the amino nitrogen of one amino acid and the carboxyl carbon of a second amino acid.

6. The directionality of a peptide is

from the free amino end (the N terminus) to the free carboxyl end (the C terminus) of the peptide.

✓ Concept Check 4.3

7. Secondary structures in proteins include the alpha helix and the beta sheet.

8. Hydrogen bonds form between the carbonyl group in one peptide bond and the amide group in another, thus allowing localized regions of the polypeptide chain to fold into either an alpha helix or a beta sheet.

9. The tertiary structure of a protein is its overall shape. It is determined by the distribution of hydrophilic and

hydrophobic R groups along the molecule, as well as chemical bonds and interactions between R groups.

2. C

3. B

4. D

5. B

6. A

Module 5

✓ Concept Check 5.1

1. Adenine and guanine are the purines, and cytosine and thymine are the pyrimidines.

2. Purines are two-ringed nitrogenous bases, while pyrimidines are one-ringed nitrogenous bases.

3. The sugar in DNA is deoxyribose.

✓ Concept Check 5.2

4. Successive nucleotides in DNA are linked by phosphodiester bonds.

5. Genetic information is stored in the sequence, or order, of nucleotides along a DNA molecule.

✓ Concept Check 5.3

6. The sugar–phosphate backbones form the banisters, and the nucleotides or bases make up the steps of the spiral staircase.

7. In DNA, A pairs with T, and C pairs with G.

✓ Concept Check 5.4

8. Characteristics that DNA and RNA share are the nitrogenous bases A, C, and G; a sugar–phosphate backbone; a 5′ 5′-phosphate end; a 3′ 3′-hydroxyl end; and an ability of their bases to base pair.

9. Characteristics that differ between DNA and RNA are that DNA contains the base T while RNA contains U, DNA

contains deoxyribose while RNA contains ribose, DNA tends to be a much longer molecule than RNA, and DNA is a two-stranded double helix while RNA is a single-stranded molecule.

Module 6

✓ Concept Check 6.1

1. The cell theory states that organisms are made up of cells; cells are the fundamental unit of life; and cells arise from other cells.

2. When scientists say that the cell is the fundamental unit of life, they are saying that the cell is the smallest, most basic entity that has all of the features of life.

✓ Concept Check 6.2

3. The cell membrane maintains the

internal environment of the cell compatible with life, and different from the environment outside of the cell. The active maintenance of a stable internal environment is called homeostasis and it is a key feature of cells and life.

4. DNA is the genetic material in all cells that stores and transmits information.

5. The central dogma describes the flow of information in a cell, where information is passed from DNA to RNA to protein.

6. Metabolism is the set of chemical reactions that take place in a cell that harness energy and materials from

the environment. These metabolic reactions are essential for life.

✓ Concept Check 6.3

7. The close relationship between structure and function can be seen in molecules, cells, organs, and even organisms. Particular structures are necessary to carry out particular functions. The close connection between structure and function is highlighted by the fact that when structure is disrupted, so is function. For example, when one amino acid is replaced with another in a protein, the resulting form and function may be altered.

8. Neurons are a type of cell that are

specialized to transmit signals along their length and convey them to another cell or organ. They have long, thin processes that allow them to carry signals across their length and target specific cells or organs. Red blood cells have a biconcave shape. This shape allows them to deform as they pass through narrow capillaries.

✓ Concept Check 6.4

9. Prokaryotic cells lack a nucleus and extensive internal compartmentalization. They have circular DNA and smaller plasmids that carry additional genes that can be transferred to other bacteria. Prokaryotic cells are small (usually 1–2 micrometers in diameter or

smaller). Because of their small size, they have a large surface-area-to-volume ratio, which means they are able to absorb nutrients from the environment to meet their metabolic needs. Eukaryotic cells have a nucleus and specialized internal structures called organelles. They have multiple linear chromosomes. They are 10 times larger in diameter and 1000 times larger in volume than a prokaryotic cell.

10. Prokaryotes include two domains of life: Bacteria and Archaea.

6. D

7. D

Module 7

✓ Concept Check 7.1

1. The nucleus stores the cell's genetic information and is the site where the information in DNA is used to synthesize RNA. The endoplasmic reticulum (ER) is the organelle in

which proteins and lipids are synthesized. The Golgi apparatus modifies proteins and lipids produced by the ER and acts as a sorting station as those molecules are targeted to their final destinations. Lysosomes contain enzymes that break down macromolecules. Vesicles transport substances from organelle to organelle within a cell and from the inside to the outside of a cell.

2. Spaces within the endomembrane system include the interior of the nucleus, ER, Golgi apparatus, lysosomes, and vesicles. The space outside the endomembrane system makes up the cytosol. One difference between these two spaces is pH. Inside lysosomes, the pH is about 5,

while outside lysosomes, the pH is about 7. This difference is significant because enzymes inside lysosomes require an acidic pH of 5, and enzymes outside lysosomes require a neutral pH of 7.

✓ Concept Check 7.2

3. Mitochondria are present in nearly all eukaryotic cells, including both plant and animal cells.

4. Mitochondria and chloroplasts are organelles involved in energy transfer; they are descendants of free-living bacteria; they are surrounded by a double membrane; and they contain circular DNA.

✓ Concept Check 7.3

5. Both the cytoskeleton and cell wall help to maintain the shape and support the structure of the cell.

6. The cell wall is present in archaea, bacteria, fungi, algae, and plants, but not animals.

5. B

6. A

7. A

Module 8

✓ Concept Check 8.1

1. As an object gets bigger, both the surface area and the volume increase, but the volume increases much more rapidly than the surface area.

2. Prokaryotic cells are smaller than eukaryotic cells, so prokaryotic cells have a higher surface area-to-volume ratio than eukaryotic cells.

3. The surface area of a cube is 6 s 2 = 6 × 5 .0 cm 2 =

$6s^2 = 6 \times 5.0\ \text{cm}^2 =$

6 × 25 .0 cm 2 = 150 cm 2

$6 \times 25.0\ \text{cm}^2 = 150\ \text{cm}^2$. The volume of a cube is s × s × s , or s 3

$s \times s \times s$, or s^3. In this case, the volume is 5 .0 cm 2 × 5 .0 cm 2 × 5 .0 cm 2 = 5

$5.0\ \text{cm}^2 \times 5.0\ \text{cm}^2 \times 5.0\ \text{cm}^2 = 5.0\ \text{cm}^3 = 125\ \text{cm}^3$. The surface area-to-volume ratio equals the surface area divided by the volume = 150 125 = 6 5 = 1 .2

$\text{volume} = \frac{150}{125} = \frac{6}{5} = 1.2$.

✓ Concept Check 8.2

4. Diffusion is the net movement of molecules from areas of higher concentration to lower concentration due to random motion.

5. Bacterial cells depend on diffusion for taking in nutrients and getting rid

of wastes. Diffusion limits the size of prokaryotes because diffusion is effective only over very short distances. In addition, their small size means they have a large amount of surface area relative to the volume of the cell, making it possible for diffusion across the cell membrane to adequately support their functions.

✓ Concept Check 8.3

6. Diffusion is increased by having a large surface area and a short distance.

7. Multicellular organisms have organs with large surface area and thin walls that allow for diffusion. These include the lining of the gut

and the lung. In addition, multicellular organisms use bulk flow to distribute oxygen and nutrients around their bodies. Bulk flow does not rely on diffusion, but instead depends on pressure differences, such as those generated by the pumping of the heart to circulate blood.

4. A

5. A

6. D

7. B

Module 9

✓ Concept Check 9.1

1. In an aqueous environment, the polar hydrophilic head group readily interacts with the polar water molecules. In contrast, the nonpolar hydrophobic tail does not readily interact with water, but instead interacts with other nonpolar tail groups or hydrophobic molecules away from water.

2. A micelle forms when the polar head group of a lipid interacts with

water, and the hydrophobic tails of the lipids interact with each other, excluding the water. Lipids can also form bilayers and liposomes, depending on the size of the head group relative to the fatty acid tails.

✓ Concept Check 9.2

3. Cell membranes are bilayers made up, in part, of phospholipids. These phospholipids have hydrophobic tails that are oriented inward, away from water. The tails associate loosely with each other by van der Waals interactions, which are individually quite weak, allowing phospholipids to move about laterally. This movement in the plane of the cell membrane is what is meant by membrane fluidity.

4. Membrane fluidity is affected by membrane composition, specifically the length and degree of saturation of the fatty acid tails. The longer the tail, the less fluid the membrane, and the more saturated, the less fluid the membrane. As a result, membranes composed of long saturated fatty acids are less fluid, and membranes composed of short unsaturated fatty acids are more fluid.

✓ Concept Check 9.3

5. Proteins associate with membranes in the following ways. First, integral membrane proteins are permanently associated with the membrane and cannot be removed without destroying the membrane itself. Most

integral membrane proteins span the cell membrane, so they have both hydrophilic and hydrophobic regions. Second, peripheral membrane proteins are temporarily associated with the membrane and can easily be experimentally separated. These proteins can be associated with either the internal or external side of the membrane. They are mostly hydrophilic and interact with the polar heads of the lipid bilayer, or the hydrophilic regions of integral membrane proteins.

6. An experiment showing that proteins move in membranes uses the fluorescence recovery after photobleaching (FRAP) technique. First, the proteins embedded in the

cell membrane are labeled with a fluorescent dye. A laser is then used to bleach a small area of the cell surface so that it no longer fluoresces. Eventually, the fluorescently labeled proteins from other parts of the cell move into the bleached area and cause it to fluoresce once again. If the proteins did not move in membranes, that area would stay bleached over time.

2. A

3. B

4. C

5. A

6. B

7. A

Module 10

✓ Concept Check 10.1

1. In diffusion, molecules move from regions of higher concentration to regions of lower concentration. This movement results from the random motion of molecules.

2. Lipids help maintain the selective permeability of the membrane by preventing charged molecules and ions, as well as most polar molecules, from diffusing freely into the cell.

They allow nonpolar molecules such as steroids and small molecules such as gases to diffuse freely through the membrane. Transmembrane proteins help transport specific molecules, such as polar molecules, by acting as channels and carriers that move molecules into and out of the cell.

3. Carbon dioxide and oxygen are two molecules that readily cross the cell membrane by simple diffusion. These are able to cross because they are small, uncharged molecules. Lipids such as steroids are also able to cross the cell membrane by simple diffusion. They are able to cross because they are nonpolar, like the inside of the lipid bilayer.

4. Water crosses the cell membrane by facilitated diffusion through channel proteins called aquaporins. Charged ions such as sodium ions (Na +) (Na^+) and potassium ions (K +) (K^+) cross nerve cell membranes by facilitated diffusion through channel proteins.

✓ Concept Check 10.2

5. Passive transport into or out of cells works by diffusion. When there is a concentration difference of a particular molecule across the cell membrane, the molecule moves from the area of higher concentration to the area of lower concentration. When a molecule cannot move across the cell membrane on its own, it is

sometimes able to passively diffuse through channel proteins or carrier proteins in the lipid bilayer by facilitated diffusion. This type of transport does not make use of cellular energy. In contrast, active transport is used to move a molecule into or out of the cell against its concentration gradient. Molecules move through transport proteins embedded in the cell membrane. This type of transport requires energy, either directly in primary active transport or indirectly in secondary active transport.

6. Both forms of active transport require an input of energy. In primary active transport, energy in the form of ATP is used directly to pump

molecules against their concentration gradient. In secondary active transport, energy in the form of ATP is used indirectly to pump molecules against their concentration gradient.

✓ Concept Check 10.3

7. Endocytosis brings macromolecules from the extracellular space into the cell interior by pinching off part of the cell membrane to form a vesicle. Therefore, the macromolecule ends up in a vesicle following endocytosis. By contrast, a macromolecule that passes through the cell membrane by passive or active transport ends up in the cytosol.

8. Endocytosis can transport much larger molecules into the cell than both passive and active transport can.

9. In endocytosis, a region of the cell membrane invaginates to form a vesicle. In exocytosis, a vesicle fuses with the cell membrane, releasing its content to the extracellular space.

Module 11

✓ Concept Check 11.1

1. Ions, such as sodium ions and potassium ions, are not able to cross the cell membrane on their own. Lipids, such as steroids, are able to diffuse across the cell membrane.

2. Most membranes have channel proteins called aquaporins that allow the rapid diffusion of water across a membrane by facilitated diffusion.

3. Water moves by osmosis from regions of low solute concentration to

high solute concentration, or from regions of high water concentration to low water concentration. Note that these both describe the same direction of water movement.

✓ Concept Check 11.2

4. When an animal cell is placed in a hypotonic solution, water moves into the cell by osmosis and the cell swells or bursts.

5. When an animal cell is placed in a hypertonic solution, water leaves the cell by osmosis and the cell shrinks.

6. Differences in solute concentration between two sides of a selectively permeable membrane lead to water

movement by osmosis. The cell wall pushes back and creates pressure called turgor pressure. Gravity also influences the flow of water.

✓ Concept Check 11.3

7. Osmoregulation is the maintenance of constant osmotic pressure inside of cells or organisms.

8. Osmoconformers are animals that regulate their internal osmotic pressure by maintaining their internal solute concentration at a level similar to that of their environment. Osmoregulators actively regulate their internal osmotic pressure, expending considerable energy to maintain an

internal solute concentration that is different from that of their environment.

9. Some marine vertebrates are also osmoconformers, including hagfish, lampreys, rays, and coelacanths. Osmoregulators include all freshwater animals, including fishes and amphibians, and all terrestrial animals, including humans. The largest group of marine vertebrates, the teleosts or bony fishes, are also osmoregulators.

Module 12

✓ Concept Check 12.1

1. Key features of eukaryotic cells are a membrane-bound nucleus that houses DNA, creating separate cellular compartments; membrane-bound organelles that further organize the cell interior and compartmentalize different cellular

processes; and dynamic membranes and cytoskeleton that can be remodeled quickly, allowing cells to change shape and transport materials throughout the cell.

2. Eukaryotes can engulf material by endocytosis, and multicellular eukaryotes can ingest whole organisms by predation. Neither of these is possible in prokaryotic organisms, such as bacteria.

✓ Concept Check 12.2

3. Chloroplasts are thought to have originated through endosymbiosis, which is a symbiosis where one partner lives within the other. Chloroplasts closely resemble

cyanobacteria and are thought to be descendants of symbiotic cyanobacteria that lived within eukaryotic cells.

4. Mitochondria are thought to have originated through endosymbiosis, which is a symbiosis where one partner lives within the other. Mitochondria closely resemble proteobacteria and are also thought to have evolved as endosymbionts.

5. Scientists hypothesize that archaea are more closely related to eukaryotes than to bacteria.

6. One hypothesis for the origin of eukaryotic cells is that the host for mitochondrion-producing

endosymbiosis was itself a true eukaryotic cell with a nucleus, cytoskeleton, and endomembrane system; subsequent engulfment of a proteobacterium led to the evolution of mitochondria. A second hypothesis for the origin of eukaryotic cells argues that the eukaryotic cell as a whole began as a symbiotic association between a proteobacterium and an archaeon, and subsequently evolved a nucleus and endomembrane system.

3. C

4. D

5. C

6. D

7. A

Module 13

✓ Concept Check 13.1

1. One form of energy is kinetic energy, or the energy of motion. Examples of kinetic energy are flexing a muscle and throwing a ball. The other form of energy is potential energy, or stored energy. Potential energy depends on the structure of

the object or its position relative to its surroundings, and it is released by a change in the object's structure or position. A ball sitting at the top of the stairs has a great deal of potential energy, which is released when the ball rolls down the stairs, at which point the energy is converted into kinetic energy.

2. Chemical energy is a form of potential energy held in chemical bonds (such as covalent bonds) between atoms in a molecule. The stronger the covalent bond, the less chemical energy it contains. The weaker the covalent bond, the more chemical energy it contains. Carbohydrates, lipids, and proteins have many carbon–carbon and

carbon–hydrogen bonds. These bonds are relatively weak and are therefore rich sources of chemical energy.

3. ATP is composed of the base adenine and the 5-carbon sugar ribose. The ribose is attached to three phosphate groups. The bonds linking these phosphate groups have a high amount of chemical energy.

✓ Concept Check 13.2

4. The first law of thermodynamics is the law of conservation of energy. It states that energy can be neither created nor destroyed; it can only be transformed from one form into another. The second law of thermodynamics states that the

transformation of energy is associated with an increase in the disorder of the universe. The degree of disorder is called entropy.

5. Chemical reactions are subject to the laws of thermodynamics, like everything else. As a result, the total amount of energy remains the same before and after a chemical reaction, but some of the energy is used to increase the entropy of the system, and only some of the energy is available to do the work of the cell.

✓ Concept Check 13.3

6. The amount of energy available to do work is called Gibbs free energy (*G*). In a chemical reaction, you

compare the free energy of the reactants and products to determine whether there is energy available to do work. This difference is called ΔG.

7. Catabolism and anabolism are both metabolic processes. Catabolism is the set of chemical reactions that breaks down macromolecules into smaller units, releasing energy, usually in the form of ATP. Anabolism is the set of chemical reactions that builds macromolecules from smaller units and requires an input of energy, usually in the form of ATP.

4. C

5. C

6. A

7. C

Module 14

✓ Concept Check 14.1

1. Enzymes increase the rate of chemical reactions. They participate in a reaction but are not themselves consumed in the process. Enzymes do not affect the equilibrium or direction

of a reaction.

2. Enzymes increase the rate of chemical reactions by stabilizing the transition state and therefore reducing the activation energy, which is the input of energy necessary to drive all chemical reactions.

✓ Concept Check 14.2

3. Enzymes reduce the activation energy of a chemical reaction by forming a complex with the substrate. As a result, the transition state, an intermediate in all reactions, is stabilized, so has a lower amount of free energy. In this way, enzymes allow the reaction to proceed along a different route than it would

otherwise take.

4. An enzyme only acts on those substrates that bind to its active site, which is the portion of the enzyme that binds substrate and converts it to product. An enzyme has to fold into its correct shape for the active site to be the right shape to bind its substrate.

✓ Concept Check 14.3

5. Temperature affects the movement of molecules. As temperatures increase, molecules move around more quickly, increasing their probability of colliding and participating in chemical reactions. As a result, enzyme activity increases

with increasing temperature up to a point. Enzymes are proteins that fold into three-dimensional shapes. The shapes of proteins are important for their functions. At high temperatures, enzymes, like all proteins, can unfold or denature. When an enzyme unfolds, it loses its shape and therefore its function.

6. Inhibitors decrease the activity of enzymes, whereas activators increase this activity.

2. C

3. A

4. C

5. B

6. D

7. C

Module 16

✓ Concept Check 16.1

1. Antenna chlorophylls transfer absorbed energy from one antenna chlorophyll molecule to another, and ultimately to the reaction center. Reaction center chlorophylls transfer electrons to an electron acceptor, resulting in the oxidation of reaction center chlorophyll molecules.

2. Photosystem II pulls electrons from water and supplies electrons to the photosynthetic electron transport chain. Photosystem I reduces NADP + $NADP^+$ to NADPH.

3. The energy from sunlight is absorbed by pigments, which transfer electrons along the photosynthetic

electron transport chain. These reactions result in a high concentration of protons in the thylakoid space in two ways: (1) the oxidation of water, and (2) the pumping of protons from the stroma to the thylakoid space. In turn, the high concentration of protons is used to synthesize ATP by ATP synthase.

4. The major products of the light reactions of photosynthesis are ATP and NADPH. Oxygen is produced as a waste product.

✓ Concept Check 16.2

5. The major inputs of the Calvin cycle are CO 2 CO_2 (from the atmosphere) and ATP and NADPH

(from the photosynthetic electron transport chain). The major outputs of the Calvin cycle are carbohydrates (triose phosphates), ADP, and NADP + $NADP^+$.

6. The three steps of the Calvin cycle are carbon fixation to produce a 6-carbon molecule, reduction to generate carbohydrates, and regeneration of the 5-carbon molecule.

7. Rubisco catalyzes the first step of the Calvin cycle, in which carbon dioxide is added to a 5-carbon molecule, producing a 6-carbon molecule and therefore incorporating carbon dioxide into an organic molecule.

8. Rubisco faces a fundamental trade-off between selectivity and speed because it can use both CO 2 CO_2 and O 2 O_2 as substrates. High selectivity of CO 2 CO_2 over O 2 O_2 requires that the reaction have a high energy barrier, leading to a lower catalytic rate.

9. Two ways plants limit the formation and effects of reactive oxygen species are antioxidants and xanthophylls. Antioxidants, such as ascorbate and beta-carotene, neutralize reactive oxygen species. Xanthophylls are yellow-orange pigments that slow the formation of reactive oxygen species by reducing excess light energy. They accept absorbed light energy directly from

chlorophyll and convert this energy to heat.

3. B

4. A

5. D

6. A

7. D

Module 17

✓ Concept Check 17.1

1. In cellular respiration, the reactants are glucose and oxygen, and the products are carbon dioxide and water. ATP is also produced in the reaction.

2. In the overall reaction for cellular respiration, glucose is oxidized and converted to carbon dioxide. Oxygen gas is reduced and converted to water.

3. The reduced molecules are NADH, FADH 2 $FADH_2$, and C 6 H 12 O 6 $C_6H_{12}O_6$, and the oxidized molecules are NAD + NAD^+, FAD, and CO 2 CO_2. The reduced forms have more chemical energy than their corresponding oxidized forms.

4. ATP is generated by substrate-level phosphorylation and oxidative phosphorylation. In substrate-level phosphorylation, a phosphorylated organic molecule directly transfers a phosphate group to ADP. This pathway produces only a small amount of the total ATP generated in the process of cellular respiration. In contrast, most of the ATP generated in cellular respiration is produced by oxidative phosphorylation. In these reactions, oxidation reactions are coupled to the reduction of electron carriers, which hand off their electrons to the electron transport chain. As electrons are passed along this chain to oxygen, protons are pumped across the inner

mitochondrial membrane, providing the potential energy to drive the synthesis of ATP.

✓ Concept Check 17.2

5. The four stages of cellular respiration are glycolysis, pyruvate oxidation, the Krebs cycle, and oxidative phosphorylation.

6. (1) Glycolysis: glucose is partially broken down to pyruvate and a modest amount of energy in the form of ATP and reduced electron carriers is released. (2) Pyruvate oxidation: pyruvate is converted to acetyl-coenzyme A, and carbon dioxide and electron carriers are produced. (3) Krebs cycle: acetyl-CoA is broken

down and carbon dioxide, ATP, and reduced electron carriers are produced. (4) Oxidative phosphorylation: electron carriers generated in stages 1–3 donate their electrons to the respiratory electron transport chain. This chain transfers electrons along a series of membrane-associated proteins to a final electron acceptor and, in the process, harnesses the energy of the electrons to produce a large amount of ATP. In aerobic respiration, oxygen is the final electron acceptor, so it is consumed, and water is produced.

✓ Concept Check 17.3

7. Three fuel molecules are carbohydrates such as glucose and

sucrose, lipids, and proteins.

8. Plants store glucose as starch, and animals store glucose as glycogen.

Review Questions

2. A

3. A

4. A

5. A

6. C

7. D

Module 18

✓ Concept Check 18.1

1. The major input of glycolysis is glucose. The major outputs of glycolysis are pyruvate, ATP, and NADH.

2. At the end of glycolysis, the energy in the original glucose molecule is contained in pyruvate, ATP, and NADH.

3. At the end of pyruvate oxidation, the energy in the original glucose molecule is contained in acetyl-CoA and NADH.

4. At the end of the Krebs cycle, the energy in the original glucose molecule is contained in ATP, NADH, and FADH 2 $FADH_2$.

✓ Concept Check 18.2

5. Oxygen gas is consumed in cellular respiration. Specifically, oxygen gas is the final electron acceptor in the electron transport chain. When it accepts an electron, it is converted to water.

6. The movement of electrons along the electron transport chain in the inner mitochondrial membrane is coupled to the transfer of protons through several enzyme complexes and electron carriers. As the electrons pass through the complexes, protons are pumped into the intermembrane space. As a result, the concentration of protons is higher in the intermembrane space compared to

the mitochondrial matrix.

7. The proton gradient generated by the electron transport chain provides a source of potential energy that is then used to drive the synthesis of ATP by ATP synthase. The protons accumulated in the intermembrane space cannot passively diffuse across the membrane, so they diffuse through a transport channel called ATP synthase. The movement of protons through the channel allows it to catalyze the synthesis of ATP from ADP and P i P_i.

✓ Concept Check 18.3

8. Yeast cells are eukaryotes. In bread making, yeast can use sugar as a food

source for ethanol fermentation. The carbon dioxide produced in the process causes the bread to rise. The ethanol is removed in the baking process.

9. In the first pathway, pyruvate is converted to acetyl-CoA, which is the starting substrate for the Krebs cycle. During the Krebs cycle, the chemical energy in the bonds of acetyl-CoA is transferred to ATP by substrate-level phosphorylation and to the electron carriers NADH and FADH 2 $FADH_2$. The second pathway is fermentation, a reaction that happens without oxygen. There are many fermentation pathways, but all rely on oxidation of NADH to NAD + NAD^+ when pyruvate or a derivative of pyruvate is

reduced. Two major fermentation pathways are lactic acid fermentation and ethanol fermentation. In the lactic acid pathway, electrons from NADH are transferred to pyruvate to produce lactic acid and NAD $+$ NAD^+. In the ethanol fermentation pathway, pyruvate releases carbon dioxide to form acetaldehyde, and electrons from NADH are transferred to the molecule to produce ethanol and NAD $+$ NAD^+.

10. Muscle tissue generates ATP during short-term exercise by converting stored glycogen to glucose. Glucose is rapidly broken down anaerobically to pyruvate, which then feeds into the lactic acid fermentation pathway. During long-term exercise,

the liver releases glucose into the blood, which is taken up by muscle cells and oxidized to produce ATP. In addition, adipose tissue releases fatty acids that are also taken up by muscle cells and broken down. These processes are slower to convert glucose and other molecules to energy; however, the end result is the production of more ATP than the fermentation pathway can produce.

Module 20

✓ Concept Check 20.1

1. The four sequential steps are stimulus, signal release, signal reception, and response. The sequence begins with the arrival of a stimulus to the signaling cell, which causes the signaling cell to release signaling molecules. Target cells are those cells that have receptor proteins that bind signaling molecules. This binding, known as a ligand–receptor interaction, leads to a response by altering the target cell's activity.

2. In quorum sensing, the stimulus is high population density. As population density increases in certain bacteria, a signaling molecule is released by the bacteria. After the signaling molecule binds to receptor proteins on the surface of the bacteria, the bacteria respond. They may respond by bioluminescing or by increasing their uptake of DNA from the environment

✓ Concept Check 20.2

3. Endocrine signals affect distant target cells only after transport in the blood or circulatory system. Paracrine signals affect neighboring target cells. Autocrine signals are released by a signaling cell and bind

to receptor proteins on that same cell, such that the signaling cell and the target cell are the same cell.

4. Both gap junctions and plasmodesmata allow materials to move directly from cell to cell by small channels linking adjacent cells.

✓ Concept Check 20.3

5. The thermostat is the sensor, and the heater is the effector. The thermostat might be set at a low temperature or be malfunctioning. If the thermostat is not receiving the stimulus that the house is cold, or if it is not sending signals to the heater, the heater will not heat the house. If the thermostat is working normally,

then the heater might be malfunctioning by failing to produce heat.

6. Cold temperature, the stimulus, is sensed by part of the brain called the hypothalamus, the sensor. The hypothalamus sends signals that stimulate involuntary shivering by muscles (the effectors), generating heat (the response) to restore the normal body temperature; increased body temperature terminates the stimulus and signals as the negative feedback in this thermoregulation system.

7. Elevated glucose levels in the blood, the stimulus, are sensed by cells of the pancreas, which in turn

secrete insulin, the signal. Cells that respond to insulin, the effectors, increase their rate of glucose uptake. The overall response is to decrease glucose levels in the blood.

Module 21

✓ Concept Check 21.1

1. A cell will respond to adrenaline only if it has adrenaline receptor proteins. Not all cells have adrenaline receptors. As a result, such cells are not directly affected by adrenaline.

2. The signaling molecule (ligand) binds to the receptor protein, and the binding changes the shape of the receptor protein.

✓ Concept Check 21.2

3. Adrenaline is amplified by a signal transduction cascade. Adrenaline binds to G protein-coupled receptors

on a cell. The activated receptor activates G proteins linked to the formation of the second messenger cAMP. Large amounts of cAMP are formed, activating many protein kinases. Each of the kinase enzymes can phosphorylate many target proteins, resulting in a large cellular response.

4. Receptor-protein kinase identifies this protein as having both a receptor function that binds signals and a kinase function that phosphorylates the receptor when the protein has been activated by ligand. These proteins have dual functions: ligand binding and enzyme function.

5. Acetylcholine binds to ligand-gated

protein channels on muscles. This binding alters the shape of the receptor protein, opening a small passageway through the membrane-spanning protein, just right for sodium ions to move through and enter the muscle. This sodium entry leads to a relay regulating muscle contraction.

✓ Concept Check 21.3

6. Signals that are water soluble are called hydrophilic signals, whereas signals that are lipid soluble are called hydrophobic signals. Receptors for hydrophilic signals are on the surface of target cells, whereas receptors for hydrophobic signals are inside cells.

7. Because hydrophobic signals are lipid soluble, they diffuse across the cell membrane of target cells, allowing them to bind to intracellular receptor proteins that will trigger a response.

8. Responses to hydrophobic signals usually turn on a gene and require the synthesis of proteins, a slower process than enzyme activation.

Module 23

✓ Concept Check 23.1

1. The penguin entered the huddle to warm up when it was cold. However, the penguins huddle together so closely that they efficiently trap heat to such high levels that a penguin in

the middle can get overheated. That is when the initial stimulus, being cold, is gone, and it is when the penguin leaves the huddle.

2. Insulin binds to its receptor to activate a response pathway that increases the rate of glucose uptake by the cell, thus lowering the concentration of glucose in the blood and terminating the stimulus for additional secretion of insulin.

3. Insulin and glucagon have opposite effects on glucose levels in the blood: insulin decreases blood glucose levels and glucagon increases blood glucose levels. Insulin, secreted by pancreatic beta cells in times of high levels of glucose, acts on its target cells to

increase uptake of glucose from the blood. In contrast, glucagon, secreted by pancreatic alpha cells in times of low levels of glucose, acts on its target cells to release glucose into the blood.

✓ Concept Check 23.2

4. The baby's head pushes against the birth canal of its mother, which is sensed by cells that cause the brain to secrete oxytocin. Binding to its receptors on the uterus, oxytocin stimulates further uterine contractions, more strongly pushing the baby's head against the birth canal, increasing oxytocin secretion, further increasing uterine contractions, and so on until delivery of the baby.

5. Baby's suckling activity at mother's nipple → nerves communicate sensation to brain → brain secretes oxytocin → oxytocin travels to mother's mammary gland and stimulates release of milk → release of milk from mammary glands.

6. The first ripening apples on a tree produce small amounts of ethylene, which when received by less ripe apples causes them to ripen and produce ethylene, so a small amount of ethylene generates a large response.

3. C

4. A

5. D

Module 24

✓ Concept Check 24.1

1. Cells need two copies of their genetic material, or DNA, so that each daughter cell can receive one copy. They also need to have adequate resources to support two daughter cells. Some cells require a signal in order to divide in two.

2. In binary fission, a cell duplicates

its DNA, increases in size, and divides into two daughter cells.

3. Eukaryotic cells produce daughter cells by mitotic cell division. In this form of cell division, the nucleus divides by mitosis and the cytoplasm divides by cytokinesis.

✓ Concept Check 24.2

4. The two main phases of the cell cycle are M phase and interphase.

5. S phase is part of interphase and it is the time when DNA is duplicated so that each daughter cell receives one copy.

✓ Concept Check 24.3

6. Centrosomes organize the mitotic spindle. The mitotic spindle attaches to kinetochores on chromatids to separate and move chromosomes during prometaphase, metaphase, and anaphase.

7. Sister chromatids are two complete copies of DNA attached by a single centromere. The sister chromatids are each a molecule of DNA but are considered a single duplicated chromosome until they split apart in anaphase. When the sister chromatids split apart, they each have their own centromere and so are each considered a chromosome.

8. The centrosome is duplicated during S phase. Because they will

eventually move duplicated chromosomes to opposite poles of a cell, lack of duplication means the chromosomes won't be able to be separated and cell division will not proceed.

9. Animal and plant cells both have cell membranes. However, plant cells have an additional covering, the cell wall, that is not present in animal cells. Therefore, plants have to synthesize cell wall plus cell membrane during cytokinesis, while animal cells only synthesize cell membrane.

6. B

Module 25

✓ Concept Check 25.1

1. Cyclins received this name after researchers observed that these proteins fluctuate in a cyclical pattern in ways that correlated with the cell cycle.

2. CDK is an acronym for cyclin-

dependent kinase. The kinase function causes the transfer of phosphates to other regulatory proteins in this process, and the activation of the kinase function is dependent upon the appropriate cyclin protein associating with the CDK protein.

✓ Concept Check 25.2

3. Three checkpoints are the DNA damage checkpoint, the DNA replication checkpoint, and the spindle assembly checkpoint.

4. The DNA damage checkpoint occurs at the G 1 / S G_1/S transition. The DNA replication checkpoint occurs at the G 2 / M G_2/M transition.

The spindle assembly checkpoint occurs at the metaphase/anaphase transition.

✓ Concept Check 25.3

5. Cells that have DNA damage can be arrested, or paused, in G 1 G_1, allowing the activity of enzymes in the nucleus to repair DNA. Cells that have not completely and accurately copied their DNA can be arrested, or paused, before entering M phase, which provides time for DNA to be completely copied. Similarly, a pause before anaphase at the spindle checkpoint can allow time for microtubules to make the correct connections.

6. If DNA damage has occurred, a DNA-damage-dependent kinase will transfer phosphates from ATP to the p53 protein. The p53 with phosphates blocks the synthesis of enzymes and other materials that are needed for DNA synthesis, resulting in G 1 G_1 arrest.

7. If the first error in the DNA is a change that allows the cell to escape regulation by the usual cell cycle regulators, subsequent errors in the DNA might also make it past a defective checkpoint. Furthermore, some of the subsequent changes might cause faster growth and result in the ability of such cells to migrate in the body, or metastasize.

Module 27

✓ Concept Check 27.1

1. The structures and molecules that are common to all species include a

cell membrane, ribosomes, DNA, and RNA.

2. The cell processes that are common to a wide range of distantly related species include cellular respiration, photosynthesis, cell signaling, and cell division.

3. When Mendel crossed two purebred parental pea plants with contrasting traits, he found that only one of the traits appeared in the offspring.

4. We would need to know the phenotype of each parental plant and the phenotypes of the offspring. If the offspring all exhibited only one of the two parental phenotypes, this would

be evidence for one allele being dominant.

5. Mendel started with purebred plants because they would carry only a single allele of a given gene.

✓ Concept Check 27.2

6. During meiosis, the maternal and paternal homologs segregate randomly into daughter cells and this causes the alleles on each chromosome to separate from each other.

7. By segregating the alleles, a recessive allele can remain in a population of organisms even if it is not exhibited for several generation,

thereby allowing genetic variation to persist.

8. With incomplete dominance, the phenotype is intermediate to that formed by the two alleles.

✓ Concept Check 27.3

9. Mendel found that when he used a dihybrid cross, the ratio of the four phenotypes matched the ratio expected from two monohybrid crosses.

10. During metaphase I, the paternal and maternal homologs line up randomly on either side of the meiotic plate, such that the probability of a given chromosome

going into a daughter cell is independent of the probability of another chromosome going into the same daughter cell.

11.

9 dominant, dominant phenotypes
3 dominant, recessive phenotypes
3 recessive, dominant phenotypes
1 recessive, recessive phenotype

✓ Concept Check 27.4

12. Pedigrees can be a useful way to understand allele inheritance in species such as humans in which controlled crosses are not possible.

13. For a rare dominant allele, we expect to see that half of the offspring of an affected parent will exhibit the phenotype and the phenotype will appear in every generation.

14. Incomplete penetrance can complicate interpretations because some individuals who have the genotype that codes for a particular phenotype fail to exhibit that phenotype.

Module 28

✓ Concept Check 28.1

1. Mendel's 9:3:3:1 ratio is based on two genes that act independently of each other, yet when there is epistasis one gene can modify the phenotype produced by another gene.

2. A chicken with the *cc* genotype has white feathers because it does not produce a dark color pigment; thus, it does not matter whether the chicken also carries the dominant allele (*I*) that can inhibit pigment production.

3. Palomino horse color is coded by one gene to be a red coat (*ee*) and then modified by a heterozygous condition at a second gene (C CR C) $(C^{CR}C)$.

✓ Concept Check 28.2

4.

	X	X
X	XX	XX
Y	XY	XY

5. For *X*-linked genes, females must inherit two copies of the allele to exhibit the trait, whereas males need to inherit only one copy of the allele to exhibit the trait.

6. Fathers transmit the gene to all of their sons and grandsons but not to their daughters. Females cannot inherit or transmit the gene, since females do not possess a *Y* chromosome.

✓ Concept Check 28.3

7. Linked genes exist when two genes are located in close proximity in a single chromosome.

8. When two genes are linked, they cannot sort independent of each other during meiosis.

9. With crossing over of *X*-linked genes, the linked genes can undergo recombination, thereby increasing

the number of different phenotypic combinations that can be expressed.

✓ Concept Check 28.4

10. Although egg cells and sperm cells both contain mitochondria and the mitochondria are both present at the moment of fertilization, sperm's mitochondria are degraded as the zygote develops.

11. For a mitochondrial disease caused by a mutant mitochondrial gene, we would expect any female with the disease to pass it on to all of her sons and daughters, with all sons and daughters exhibiting the disorder.

Module 31

✓ Concept Check 31.1

1. DNA contains the bases A, G, T, and C. RNA contains the bases A, G, U,

and C.

2. DNA stores genetic information in the sequence, or order, of nucleotides along its length.

✓ Concept Check 31.2

3. The usual flow of information in a cell is DNA to RNA to protein.

4. Gene expression refers to the turning on of a gene so that it makes a functional product, such as a protein. Gene regulation refers to the control of gene expression; it is the set of mechanisms that determines when, where, and at what level genes are expressed.

✓ Concept Check 31.3

5. Prokaryotes have a single circular chromosome. Eukaryotes have multiple linear chromosomes.

6. In prokaryotes, the single circular chromosome forms a nucleoid, which is located in the cytoplasm of the cell. In eukaryotes, the linear chromosomes are located in the nucleus.

Review Questions

1. A

2. A

3. C

4. C

5. D

6. D

7. A

Module 32

✓ Concept Check 32.1

1. During DNA replication, each parental strand serves as a template for a new complementary strand of DNA because of the specific pairing of the bases: an A on the template will always specify a T on the new strand, a G on the template will always specify a C on the new strand, and so on. The end result of DNA replication is two DNA molecules that have a

sequence that is identical to the original molecule.

2. DNA replicates semiconservatively. In other words, the new DNA molecules are composed of a parental (old) strand and a daughter (new) strand. During DNA replication, the two strands separate ("unzip") from each other and both parental strands are used as a template for the replication of two new daughter strands.

✓ Concept Check 32.2

3. Helicase unwinds the parental strands at the replication fork. Topoisomerase relieves the stress that results from unwinding the double

helix. RNA primase synthesizes a short stretch of RNA. DNA polymerase synthesizes new DNA strands. DNA ligase joins DNA (Okazaki) fragments together on the lagging strand.

4. The orientation of the two DNA strands is antiparallel. This means that the 3 ′ $3'$ hydroxyl end of one strand is opposite the 5 ′ $5'$ phosphate group of the other strand. When the two strands separate and DNA replication occurs, nucleotides are added to the 3 ′ $3'$ end of both strands, so DNA replication occurs in the 5 ′ $5'$ -to-3 ′ $3'$ direction.

5. Similarities of the resulting daughter strands from DNA

replication are that they encode the same genetic information in the form of a nucleotide sequence; they are paired with one of the parental DNA strands; and they are both synthesized in the 5′-to-3′ direction.

6. The two daughter strands are synthesized in different ways. The leading strand has the 3′ end of its DNA pointed toward the replication fork and thus is synthesized as one long, continuous polymer. The lagging strand has its 5′ end pointing toward the replication fork. Because DNA can only be replicated in a 5′-to-3′ direction, the lagging strand is synthesized in short, discontinuous pieces. Each new

piece, or Okazaki fragment, is elongated at its 3′ 3′ end until it reaches the piece in front of it.

✓ Concept Check 32.3

7. DNA replication is precise because errors, or mutations, can be harmful or lethal to the cell or organism.

8. DNA polymerase has a proofreading function that allows it to identify a mismatched base and insert the correct one in its place.

Module 33

✓ Concept Check 33.1

1. The usual flow of genetic information is from DNA to RNA to protein.

2. The RNA transcript is the reverse complement of the template strand, so it has the sequence 5′ 5′-

AUCGCUGAAAGU-3 ′ $3'$.

✓ Concept Check 33.2

3. RNA polymerase is the enzyme that synthesizes RNA from DNA.

4. The incorporation of a nucleotide with a 3 ′ $3'$-H atom rather than a 3 ′ $3'$-OH group will stop subsequent elongation because the 3 ′ $3'$-OH group is necessary to attack the high-energy phosphate bond of the incoming nucleoside triphosphate.

✓ Concept Check 33.3

5. Three modifications of the primary transcript that occur during RNA processing in eukaryotic cells are the

addition of the GTP cap, the addition of the poly(A) tail, and RNA splicing.

6. The GTP cap allows the mRNA to be recognized by the ribosome and helps stabilize the mRNA. The poly(A) tail also helps to stabilize the mRNA, and plays a role in the export of the mRNA out of the nucleus and into the cytoplasm.

7. RNA splicing is the process by which exons are joined and introns are removed from a primary transcript. A single transcript with multiple introns may be spliced in different ways to generate different mRNAs and different protein products with different functions. Thus, this alternative splicing

contributes to the diversity of the genetic information stored in DNA.

8. Three types of noncoding RNAs are ribosomal RNA (rRNA), transfer RNA (tRNA), and small regulatory noncoding RNA.

Review Questions

1. C

2. A

3. C

4. D

5. D

6. D

7. B

Module 34

✓ Concept Check 34.1

1. Ribosomes are the sites of translation, or protein synthesis. They bring all of the components together and catalyze the chemical reaction in which one amino acid attaches to the next one in line.

2. The tRNAs do the translating between nucleotide sequence and amino acid because each one has an anticodon that base pairs with a specific codon, and it carries an amino acid to the growing polypeptide chain.

3. A codon in mRNA is a group of three nucleotides that codes for a particular amino acid. The sequence of the codons in the mRNA gives rise to the order of the resulting amino acid polypeptide chain.

4. The codons are translated by tRNAs. The sequence of each tRNA includes a group of three nucleotides called an anticodon that is complementary in sequence and, therefore, can recognize and bind to a specific codon in the mRNA. Each tRNA is also bound to a specific amino acid on the 3′ 3′ end of the molecule.

✓ Concept Check 34.2

5. There are three reading frames, as follows:

UUU GGG UUU GGG UUU GGG

U UUG GGU UUG GGU UUG GG

UU UGG GUU UGG GUU UGG G

6. UUU codes for phenylalanine (Phe). GGG codes for glycine (Gly).

✓ Concept Check 34.3

7. Initiation factors bind to the GTP cap of the mRNA (in eukaryotic cells) or at an internal sequence (for prokaryotes) and recruit the small subunit of the ribosome and a tRNA bound to methionine. This complex then moves along the mRNA until it

finds the start codon AUG, coding for methionine. The large ribosomal subunit then joins the complex and causes the initiation factors to be released. The tRNA attached to Met is then bound to the ribosome.

8. The next tRNA, determined by the codon of the mRNA, binds to the ribosome. The ribosome then catalyzes a reaction in which a peptide bond is formed between the carboxyl group of Met and the amino group of the next amino acid. The tRNA that was originally bound to Met is then released, and the ribosome slides to the next codon on the mRNA.

9. The ribosome continues in this

fashion, shifting down the mRNA one codon at a time, adding amino acids to the growing peptide chain.

10. When the ribosome complex comes across a stop codon (UAA, UAG, or UGA), a protein release factor binds to the ribosome and causes the bond between the polypeptide chain and the last tRNA to break. Once the polypeptide chain is released, the ribosomal subunits disassociate from the mRNA and each other, and translation is complete.

Review Questions

1. C

2. C

3. C

4. B

5. D

6. C

7. C

Module 35

✓ Concept Check 35.1

1. Gene expression is the set of processes by which DNA is transcribed into mRNA, and mRNA is translated into protein. Gene regulation controls when, where, and how much gene expression occurs. Gene regulation makes sure that the

gene is turned on in the right place, at the right time, and in the right amount.

2. The different levels of gene regulation are the various steps at which the process of gene expression can be controlled, such as transcription, RNA processing, and translation.

✓ Concept Check 35.2

3. An activator is a protein that binds to a sequence of DNA and is required for transcription. So, the gene is usually off, but is turned on in the presence of an activator. An inducer binds to and interferes with the action of a repressor. The repressor

binds DNA and turns off transcription. Therefore, in the presence of an inducer, the repressor is not able to bind to DNA and transcription proceeds.

4. Binding with a small molecule results in a conformational change in one part of the protein that alters its structure at other sites in the protein. This is called an allosteric interaction. The changes in structure may affect the ability of the protein to bind to DNA.

✓ Concept Check 35.3

5. One mechanism that produces more than one protein from a single gene is alternative splicing. The

mRNA can be spliced in different ways to yield different proteins by either splicing out or leaving in exons. A second mechanism that produces more than one protein from a single gene is RNA editing. RNA editing is a process in which individual bases in mRNA are altered. In some cases, the edit leads to a change in the amino acid sequence of the protein.

6. Small regulatory RNAs are not translated into proteins. As a result, they are often called noncoding RNAs because they do not code for proteins. By contrast, mRNAs are translated into proteins.

7. One way in which gene expression can be influenced after mRNA is

processed and leaves the nucleus is through the actions of small regulatory RNAs that can either degrade mRNA or inhibit translation. A second way is to alter the GTP cap of the mRNA, so translation initiation cannot occur. A third way is altering or deleting the poly(A) tail, which inhibits translation. A fourth way is to modify the protein after it is synthesized through post-translational modification.

✓ Concept Check 35.4

8. DNA in a cell is wrapped around a group of histone proteins called a nucleosome. When DNA is coiled tightly around the nucleosome, the DNA is not accessible to transcription

factors. However, when the chromatin unravels from the nucleosome through histone modifications, transcription factors can access the DNA and transcribe it.

9. Bases can be modified by attaching a methyl group to cytosine. When several cytosines are methylated near a promoter, that gene is usually repressed or turned off.

Review Questions

1. C

2. A

3. B

4. C

5. B

6. D

Module 36

✓ Concept Check 36.1

1. Totipotent cells can give rise to a complete organism. Pluripotent cells are able to give rise to any cell of the body but cannot give rise to an entire organism. Multipotent cells are further along in differentiation than pluripotent cells and can form a limited number of specialized cell types. The terms are appropriate because multipotent cells give rise to multiple cell types, pluripotent cells to more cell types, and totipotent cells

to all cell types.

2. A cell from an early embryo has more developmental potential than a cell from a later embryo because it is less differentiated and can give rise to more cell types.

3. Stem cell therapy for an individual might someday consist of taking that person's own cells and reprogramming them into stem cells. These cells could be programmed to replace burned tissue, defective heart muscle, regenerate nerve cells, and so on.

✓ Concept Check 36.2

4. *Pax6* encodes a transcription factor

that binds to regulatory sequences in or near eye-specific genes to affect gene expression.

5. Evolutionary conservation is the observation that a gene is the same or very similar among many different organisms, even distantly related ones. From this observation, scientists infer that the gene was present in a common ancestor and has not changed very much if at all over long periods of time.

✓ Concept Check 36.3

6. Combinatorial control describes the regulation of gene transcription according to the mix of transcription factors in the cell.

7. Although a gene may have binding sites for activators and repressors, it is the combination of transcription factors present in a cell and bound to DNA that determines whether it is expressed. In this case, the gene will be transcribed because of the presence of the activator bound to its regulatory sequence.

Review Questions

1. C

2. A

3. D

4. A

5. A

6. C

Module 37

✓ Concept Check 37.1

1. Missense mutations alter a codon so that the result is a single amino acid replacement in a protein; they may affect protein function if the new amino acid causes protein misfolding or impairs interactions with other molecules. Silent mutations produce a codon that encodes the same amino acid as the nonmutant version. Nonsense mutations result in stop codons that terminate polypeptide elongation.

2. An insertion of three nucleotides

will add one amino acid to a protein, while a deletion of three nucleotides will delete one amino acid from a protein. In general, the effects of small insertions or deletions in proteins depend on whether their length is a multiple of three. If the length is a multiple of three, then the result is the insertion or deletion of amino acids in the polypeptide chain. Insertions or deletions that are not a multiple of three shift the reading frame so that amino acids attached to the polypeptide chain following the site of the insertion or deletion are incorrect.

✓ Concept Check 37.2

3. A genotype is the genetic

composition of a cell or organism, which in this case is *SS*. A phenotype of a cell or an organism refers to its observable features, which in this case is the disease sickle-cell anemia. The *S* allele produces an abnormal hemoglobin molecule, which causes it to bind in red blood cells, leading to the symptoms of the disease.

4. Harmful mutations reduce survival and reproduction; beneficial mutations increase survival and reproduction; and neutral mutations have no effect on survival or reproduction.

5. Designating a mutation as simply harmful, beneficial, or neutral does not account for whether it is

homozygous or heterozygous or the influence of the environment on the organism, which may determine how the mutation ultimately affects the individual's ability to survive and reproduce. For example, the *S* allele is very harmful as a homozygote but not as a heterozygote. Furthermore, the *S* allele is beneficial as a heterozygote in areas where malaria is widespread, but not in areas where malaria does not occur.

6. Because only a small fraction of the human genome codes for proteins or other functional elements, most mutations are neutral and don't have an observable effect.

✓ Concept Check 37.3

7. Mutagens are agents that increase the probability of mutation. Some common mutagens are: X-rays; ultraviolet light; bleach and hydrogen peroxide; and chemicals that are highly reactive, such as those in cigarette smoke.

8. Conjugation is the direct transfer for DNA from one cell to another; transformation is the uptake of DNA released from cells into other cells; and transduction is the transfer of DNA from one cell to another by a virus.

Module 38

✓ Concept Check 38.1

1. PCR is used to generate many copies of, or amplify, a piece of DNA.

2. The three steps of PCR are (1) denaturation of the double-stranded DNA into two individual strands, (2)

annealing of the two primers to their complementary sequence on the DNA template strands, and (3) extension of the parental DNA strands through elongation (5′ to 3′) by DNA polymerase (by extending the primers).

3. PCR can be used for a variety of purposes such as matching a person's DNA sequence to evidence found at a crime scene. Paternity tests are performed in a similar way. PCR can be used to identify an organism based on a known conserved region of its DNA. It can also be used to mass produce certain sequences of DNA for DNA-based vaccines.

✓ Concept Check 38.2

4. DNA is negatively charged, so pieces of DNA move through a gel when an electric current is applied, toward the positive electrode and away from the negative electrode.

5. The distance that the DNA pieces move through the gel is based on their size, with smaller fragments moving more slowly and therefore shorter distances, and larger fragments moving more quickly and therefore longer distances in a given amount of time.

✓ Concept Check 38.3

6. In Sanger sequencing, a DNA template, DNA primer, DNA polymerase, and normal nucleotides

are necessary in addition to dideoxynucleotides.

7. The sequence of the template strand is antiparallel to the synthesized strand and inferred from complementary base pairing as 5′ 5′-CCTCGGT-3′ 3′.

✓ Concept Check 38.4

8. A restriction enzyme cuts DNA at specific, short sites.

9. Gel electrophoresis is a technique that can be used to determine the sizes of DNA fragments following digestion by restriction enzymes.

✓ Concept Check 38.5

10. A recombinant DNA molecule is a single DNA molecule that contains sequences from two or more different species.

11. The mammalian gene can be expressed in a bacterium through its insertion into a vector DNA that can be replicated in the bacterium. Donor DNA containing the mammalian gene and vector DNA are joined in a single plasmid, creating a recombinant DNA molecule. The vector DNA is then inserted into the bacterium by transformation. The plasmid is replicated and expressed in the bacterium just like any other DNA sequence.

Module 39

✓ Concept Check 39.1

1. Viruses all have a nucleic acid genome, which can be DNA or RNA. They also all have a protein coat called a capsid.

2. Common shapes of viruses include

the head-and-tail structure of some bacteriophages, the helical structure of tobacco mosaic virus, the icosahedral structure of adenovirus, and enveloped viruses such as coronaviruses and influenza virus.

3. Living organisms are made up of one or more cells that regulate the passage of substances into and out of them, store and transmit information, and harness energy from the environment. Viruses do not have these features, so are not considered to be living. They require a host cell to carry out their functions, replicate, and make more viruses.

✓ Concept Check 39.2

4. To infect a cell, a virus binds to a protein on the surface of the cell. Therefore, it is the presence of specific proteins on the cell surface that determines what type of cell a virus is able to infect.

5. Lysis is the process in which a cell bursts open to release progeny viruses. Lysogeny is the process in which the viral DNA is incorporated into the bacterial chromosome.

✓ Concept Check 39.3

6. The influenza virus causes the flu. SARS-CoV-2 causes the disease COVID-19. HIV causes AIDS.

7. Pathogenicity refers to whether an

infectious agent, such as a virus, causes disease. A pathogenetic virus causes disease, and a nonpathogenic virus does not cause disease. Virulence describes the degree of severity of the disease. A highly virulent virus causes more severe disease than a less virulent virus does.

✓ Concept Check 39.4

8. Viruses infect all types of organisms, including bacteria, archaea, protists, fungi, plants, and animals.

9. Viruses are able to lyse (break open) phytoplankton, which slows their growth and returns their

nutrients to the water.

Module 40

✓ Concept Check 40.1

1. Species differ in size, shape, color, movement, reproduction, how they harness energy, and many other ways.

2. Species have the same genetic material (DNA), the same amino acids that are used to build proteins, and the same biochemical machinery to build proteins.

3. Evolution is change over time. Traits that organisms share are often inherited from a common ancestor that had that trait. Traits that set organisms apart often arise over time after divergence from a common ancestor. This process was described by Charles Darwin, who called it descent with modification.

✓ Concept Check 40.2

4. Organisms vary because of differences in the environment (environmental variation) and differences in genetic material (genetic variation).

5. Genetic variation ultimately stems from mutations, or changes in the genetic material.

✓ Concept Check 40.3

6. Evolution is change in a population's genetic makeup over time, and natural selection is a mechanism or way by which this change occurs.

7. Natural selection results in

antibiotic resistance. Before the application of antibiotics, bacteria with antibiotic resistance exist in low numbers. The application of antibiotics allows these bacteria to grow and reproduce more successfully than those that are susceptible to antibiotics. Over time, the use of antibiotics selects for antibiotic resistance among bacteria.

Review Questions

6. A

7. A

Module 41

✓ Concept Check 41.1

1. An adaptation is a close fit between an organism and its environment. Desert plants are adapted for dry conditions. A predator such as a shark or an eagle has sharp teeth and powerful jaws. A bacterium that lives in hot springs has a heat-stable DNA polymerase that functions at high temperatures. Each of these traits allows the organism to survive and

reproduce well in the environment in which it lives.

2. The four postulates are: (1) there is variation among individuals; (2) some of this variation is passed on to offspring; (3) there is competition among individuals of a population, with some individuals surviving and reproducing more than others as a result of this variation; and (4) variations that are best suited to a particular environment will be passed on to the next generation more than variations that are less suited.

3. Fitness is the ability to survive and reproduce in a particular environment.

4. Fitness can be measured by the number of individuals that survive, by the number of offspring each individual has, or by the survival of those offspring.

✓ Concept Check 41.2

5. Convergent evolution

6. Natural selection increases the frequency of beneficial alleles, and decreases the frequency of harmful alleles.

7. Stabilizing selection is a form of selection that acts against extreme values of a trait and favors intermediate values of a trait. Human birth weight is an example.

8. Directional selection is a form of selection that favors one extreme and acts against the opposite extreme, so the trait moves in one direction over time (bigger, faster, redder, etc.). The change in the population from lighter moths to darker moths in the United Kingdom in the late 1800s is an example.

9. Disruptive selection favors two extremes and acts against intermediate values, leading to the evolution of two distinct populations. The evolution of early- and late-feeding apple maggots is an example.

✓ Concept Check 41.3

10. Humans have produced breeds of

dogs, cats, and many other animals and plants by artificial selection.

11. In both cases, there is phenotypic variation, and some individuals survive and reproduce more than others. In addition, in both cases the result is a change in the population over time, or evolution.

12. In artificial selection, humans do the selecting, whereas in natural selection, selection is the result of competition in nature. In artificial selection, breeders typically have a goal in mind, for example, cows that produce more milk. In natural selection, there is no goal.

✓ Concept Check 41.4

13. Sexual selection is a form of directional selection.

14. Intrasexual selection typically involves competition between males (such as direct combat), whereas intersexual selection typically involves males advertising to females with bright colors, melodic songs, or elaborate courtship dances.

6. A

Module 42

✓ Concept Check 42.1

1. A phenotype is a trait or observable characteristic of an organism, whereas a genotype is its genetic makeup.

2. Phenotype variation is the result of differences in the genetic material among organisms as well as differences in the environment.

3. Because mutations are changes in an organism's DNA sequence, the mutation may harm the organism by damaging a protein or process,

benefit the organism by improving the function of a protein or process, or have no discernable effect on a protein or process.

✓ Concept Check 42.2

4. Genetic variation is the result of mutation and recombination.

5. Mutation is the ultimate source of all present-day genetic variation.

6. By random, scientists mean that mutations arise without any regard to whether that mutation will be beneficial or harmful to the organism.

7. Point mutations are changes to a single base or nucleotide. Insertions

and deletions are additions or removals of one or more bases. Transposable elements can jump into or out of a region of DNA.

✓ Concept Check 42.3

8. Population geneticists typically use allele frequency as a measure of genetic variation in populations.

9. Allele frequency is the proportion of a given allele among all the alleles of a gene in a population.

10. The allele frequency is the number of copies of allele *A* divided by the total number of alleles of that gene. So, in this case, it is 25 divided by 100, or $25\ 100 = 1\ 4 = 0.25$

$$\frac{25}{100} = \frac{1}{4} = 0.25.$$

Review Questions

3. B

4. D

5. B

6. C

7. A

Module 43

✓ Concept Check 43.1

1. Evolution is a change in the genetic makeup of a population over time. Because we can measure the genetic makeup of a population by its allele or genotype frequency, evolution is specifically a change in allele and/or genotype frequency over time.

2. The possible genotypes are *CC, Cc,* and *cc*.

3. The frequency of allele *C* is 30 divided by the total number of alleles, which in this case is 30 + 20 = 50 $30 + 20 = 50$. So, the frequency of allele *C* is 30 divided by 50 = 30 50 = 6 10 = 0.6 $50 = \frac{30}{50} = \frac{6}{10} = 0.6$.

✓ Concept Check 43.2

4. The five mechanisms of evolution are natural selection, genetic drift, migration, mutation, and nonrandom mating.

5. Natural selection is the only mechanism of evolution that results in adaptations.

6. Natural selection is an evolutionary mechanism that causes a change in allele or genotype frequencies within a population over time based on the relative fitness of each genotype in a particular environment. Due to competition for limited resources, those individuals with alleles that allow them to survive and reproduce better than individuals without those alleles are more likely to pass on their

genes to the next generation, thereby enriching subsequent generations of the population for these alleles and allowing for adaptation of the population to its environment over time.

7. Nonrandom mating causes the frequency of a genotype in a population to change without a change in the frequency of the alleles. In nonrandom mating, individuals of one genotype may preferentially mate with individuals of the same genotype or a different genotype, maintaining the same frequencies of alleles from generation to generation but configuring them preferentially in certain genotypes.

✓ Concept Check 43.3

8. If a population is at Hardy–Weinberg equilibrium, you can use allele frequencies to calculate genotype frequencies. In this case, p represents the allele frequency of one allele and q represents the frequency of the second allele. The frequency of homozygous dominant individuals is determined by calculating p 2 p^2, the frequency of homozygous recessive individuals is determined by calculating q 2 q^2, and the frequency of heterozygous individuals is determined by calculating $2pq$.

9. If a population is not in Hardy–Weinberg equilibrium, we can conclude that the population is

evolving.

6. A

Module 46

✓ Concept Check 46.1

1. The base of the tree is called the root. The lines are the branches. The points where lines split into two are nodes. And the tips of the branches are present-day organisms, called taxa.

2. You can't read a phylogenetic tree by looking at the order of taxa (organisms) along the tips because this order can be changed by rotating the nodes. Rotating nodes does not change the evolutionary relationships, but it does change the order of taxa along the tips. Instead, phylogenetic trees should be read by following the branching order over time, from the past to the present.

3. A clade is a group of organisms that includes a common ancestor and all the descendants of that common ancestor. It is also called a monophyletic group and it reflects the evolutionary history of a particular group.

✓ Concept Check 46.2

4. Two species can share a trait either because the common ancestor of the two species had the trait and it was retained over time, or because the two species evolved the trait independently of each other as an adaptation to similar environments by convergent evolution.

5. Homologous and analogous traits are both shared by two different groups of organisms. However, homologous traits are shared because of common ancestry and analogous traits are shared because of convergent evolution. In addition, homologous traits evolve once, whereas analogous traits evolve more

than once.

✓ Concept Check 46.3

6. Evolutionary trees can be built using shared derived characters, or they can be built using distance methods, which rely on the overall similarity between groups of organisms. In both cases, the traits can be morphological or molecular.

7. Molecular traits are useful because they offer an abundance of characters. For example, every base in DNA and every amino acid in a protein is a unique character, so a single molecule provides many independent pieces of data.

✓ Concept Check 46.4

8. Scientists use molecular data to track virus samples and build trees.

9. Building evolutionary trees can be used to track viral and bacterial infections in humans, figure out the source of an invasive species, and place species in their proper taxonomic group which in turn can inform treatment.

4. C

5. A

6. A

7. C

Module 47

✓ Concept Check 47.1

1. Although no one definition perfectly describes the genetic boundaries between different organisms, the biological species concept (BSC) defines a species as a group of organisms that can share genetic material by interbreeding with one another to produce viable, fertile offspring. By this definition, organisms that cannot successfully

reproduce with one another belong to different species.

2. The biological species concept defines species based on their ability to interbreed to generate viable, fertile offspring, so organisms that reproduce asexually (such as bacteria) and those that are extinct cannot be easily characterized by this definition. A combination of phylogenetic and ecological species concepts works better to differentiate species in these organisms.

✓ Concept Check 47.2

3. Reproductive barriers that prevent fertilization (pre-zygotic) include reproducing in different places and at

different times, differences in mating behaviors such as courtship rituals, mechanical blocks to fertilization such as differences in the genitalia required for mating, and incompatibilities of the gametes that can prevent the fusion of sperm and egg.

4. After fertilization has occurred, post-zygotic barriers include the inability of zygotes formed from gametes of different species to fully develop into adults (hybrid inviability) or the inability to develop into fertile adults (hybrid sterility). These barriers typically result because of differences at the genetic level, such as differences in the number of chromosomes between the two

species.

✓ Concept Check 47.3

5. Allopatric speciation occurs after a geographic barrier physically separates two populations from each other. This barrier limits gene flow and promotes genetic divergence of the two populations as they adapt to their different environments. Sympatric speciation is the divergence of one group of organisms into two distinct species in the same geographical area. In sympatric speciation, gene flow between the diverging subpopulations is typically limited by strong selection against hybrid offspring.

6. Allopatric speciation can occur if a subset of a population moves to a new location far from the original population (dispersal)—for example, if a hurricane blew a group of beetles to a distant island off the coast of the mainland. Allopatric speciation can also occur by vicariance, when a geographic barrier divides a population into two distinct groups. An example of allopatric speciation by vicariance would be if a lake receded and began to dry out, leaving only smaller, isolated ponds behind. Fish from a single species might be split among several different ponds, each of which would then undergo genetic divergence. Ultimately, these different pond populations might

evolve into new species.

7. Volcanic island chains, such as the Galápagos Islands, offer many examples of adaptive radiation because they are isolated, depend on the chance process of colonization, and have many ecological opportunities available to them.

Module 48

✓ Concept Check 48.1

1. Extinction is the loss of a group of organisms, such as a species.

2. On a phylogenetic tree, you can illustrate extinction by drawing a branch that does not extend all the way to the present.

3. Speciation and extinction over time determine the total number of species.

✓ Concept Check 48.2

4. Extinction is the loss of a single group of organisms. A mass extinction is a relatively rapid and large loss of many species of organisms.

5. There is strong evidence that a meteorite struck Earth 66 million years ago. As a result, ecosystems were severely disrupted, leading to the extinction of many groups of organisms, including the dinosaurs.

6. All five mass extinctions resulted from global ecological stress, such as climate change, volcanism, and so on. They all led to a large loss of biodiversity. And they all took place over a relatively short period of time.

✓ Concept Check 48.3

7. Adaptive radiation tends to occur after mass extinction events or whenever there are many open habitats. The same process occurs when an organism finds itself on a newly formed volcanic island where there are few colonists.

8. After the extinction of the dinosaurs 66 million years ago, mammals came to dominate many ecosystems. In fact, the next time period is informally called the Age of Mammals.

✓ Concept Check 48.4

9. Humans are affecting other species

by destroying habitats, polluting the air and water, introducing invasive species, hunting, overharvesting, and burning fossil fuels.

10. The dodo, Bali tiger, and northern white rhinoceros are examples of organisms that have gone extinct as a result of human activities.

6. B

Module 49

✓ Concept Check 49.1

1. Variation is the raw material on which evolution acts. Therefore, populations with little genetic variation may be well adapted to the current environment, but may not be able to adapt if the environment changes.

2. Many of the crops and plants we grow and eat, such as corn, wheat, and bananas, have very little genetic variation and are vulnerable to pathogens. Endangered species, such as sea otters, cheetahs, and

Tasmanian devils, also have little genetic variation.

✓ Concept Check 49.2

3. Populations with a lot of genetic variation are able to adapt in many different ways because there are lots of variants. A variant with low fitness in one environment may have high fitness in another.

4. Many strains of bacteria have considerable genetic variation, which enables them to evolve resistance to many kinds of antibiotics.

✓ Concept Check 49.3

5. Individuals that have one *A* allele

and one *S* allele (*AS* individuals) have some protection against malaria compared to *AA* individuals. In addition, *AS* individuals do not get sickle-cell anemia, like *SS* individuals do.

6. *AA* individuals are well adapted to a malaria-free environment because there is no benefit to having the *S* allele in that environment, but there is a downside to having anemia.

7. The effect of a mutation on fitness (that is, whether it is beneficial, harmful, or neutral) depends on not just the mutation but also the environment. Therefore, a different environment can affect which variant is most fit.

7. D

Module 50

✓ Concept Check 50.1

1. The atmosphere of the early Earth contained carbon dioxide (CO_2)

(CO_2), nitrogen (N 2) (N_2), carbon monoxide (CO), hydrogen gas (H 2) (H_2), hydrogen sulfide (H 2 S) (H_2S), ammonia (NH 3) (NH_3), and methane (CH 4) (CH_4), but no oxygen gas (O 2) (O_2). Therefore, it is often described as a reducing atmosphere due to the lack of oxygen gas.

2. The Miller–Urey experiment demonstrated that amino acids can be synthesized from inorganic substances, such as H 2 H_2, H 2 S H_2S, NH 3 NH_3, and CH 4 CH_4. Amino acids are the building blocks, or subunits, of proteins. Therefore, organic molecules might have been synthesized under conditions present on ancient Earth, which is a first step

in making a cell, and therefore life.

✓ Concept Check 50.2

3. Experiments showing that nucleic acids can be synthesized from nucleotides, and proteins from amino acids, are critical for our understanding of how life might have originated. They demonstrate that organic molecules could be synthesized before life originated.

4. The observation that some RNA molecules can store information in their sequence of nucleotides, copy this information, and catalyze chemical reactions suggests that many of the functions important for life could have been carried out by

RNA.

✓ Concept Check 50.3

5. All cells require an archive of information, a membrane to separate inside from outside and maintain the inside compatible with life, and the ability to harness energy from the environment.

6. The fact that phospholipids are able to form a membrane spontaneously, in the absence of an enzyme or a cell, suggests that this might have been a critical step in the formation of the first cell. For example, a liposome might have formed and encapsulated a self-replicating RNA with catalytic

properties.

7. Metabolism describes the entire set of chemical reactions that convert molecules into other molecules and transfer energy in living organisms. In essence, these are the chemical reactions that sustain life. The earliest cells might have used fermentation reactions, anaerobic respiration, or photosynthesis to harness energy from the environment.

✓ Concept Check 50.4

8. The first cell was prokaryotic, a cell that lacks a nucleus and other internal membranes.

9. All the oxygen we breathe comes

from a process called oxygenic photosynthesis (sometimes simply called photosynthesis). The first organisms to evolve the biochemical machinery for photosynthesis were cyanobacteria, a type of bacteria. They evolved this ability about 2.5 billion years ago.

10. The Cambrian explosion was a rapid diversification of marine animals that took place about 541 million years ago. Many of the animal groups that are alive today first evolved at this time.

Module 51

✓ Concept Check 51.1

1. While a population is a group of individuals from the same species, it takes multiple populations to make up a community of interacting species.

2. Communities are comprised of all populations in a given area while ecosystems include both the living and the nonliving factors, such as water, temperature, and sunlight.

3. The laws for the conservation of energy and matter tell us that neither can be created or destroyed, but both can change forms, which means we can follow the movement of matter and energy in ecological systems.

✓ Concept Check 51.2

4. By responding to changes in the environment, organisms can use their behavioral and physiological responses to improve their evolutionary fitness.

5. A decreasing photoperiod indicates that winter is coming, and less food will be available, so the birds could use this environmental cue to migrate south to warmer areas where more food is available.

6. Kinesis is random movement in response to external environmental stimuli, and taxis is movement in a specific direction.

✓ Concept Check 51.3

7. Communication is the transfer of information between two individuals in which the sender is trying to manipulate the behavior of the receiver.

8. If the warning call helps protect the individual's offspring (or other relatives), the calling individuals would experience increased fitness.

9. The predator-specific calls provide unique information regarding the location of the predator, which helps other members of the species know both where to look for the predators and what evasive tactics might work the best against aerial versus ground predators.

✓ Concept Check 51.4

10. If the mice learned through habituation, they would initially show a fear response to the plastic hawk, but over time they would no longer

show fear.

11. Innate behaviors are performed correctly with no previous experience, while learned behaviors require past experiences to perform the behavior correctly.

12. Cooperative behavior has several benefits, including finding food, identifying predators, group defense, and prey capture.

4. C

5. A

Module 52

✓ Concept Check 52.1

1. Endotherms regulate their body temperature to be constant regardless of the external temperature while ectotherms have a body temperature that is more affected by the external environment, although they can behaviorally adjust to thermoregulate.

2. When the air temperature is cold at night, they can burrow to conserve their body heat. When air temperature is cold during the day, they can bask in the sunlight to

elevate their body temperature. When air temperature is too hot during the day, they can seek shade and cool soils to lower their body temperatures.

3. Larger animals have a lower per-kg metabolic rate because they lose less body heat due to their small surface area relative to their volume.

✓ Concept Check 52.2

4. Autotrophs, primary consumers, secondary consumers, and tertiary consumers.

5. A food chain is a simple, linear depiction of how energy and matter flow between species. A food web is a

more complex depiction of how energy and matter flow between multiple species and includes species that feed on multiple trophic levels.

6. The ecological efficiency between adjacent trophic levels is approximately 10%, so each successive trophic level only contains about 10% of the energy of the trophic level below it.

✓ Concept Check 52.3

7. Pools represent where the carbon resides, while processes indicate how carbon is moved from one pool to another.

8. Human combustion of fossil fuels

has moved buried carbon to Earth's surface, and its combustion has further moved carbon into the atmosphere.

5. A

Module 53

✓ Concept Check 53.1

1. Given that age structure affects how many individuals are reproductively mature versus immature, age structure affects the number of breeding individuals and therefore the number of offspring produced.

2. N = (C R) × M = 20 10 × 20 = 40

$$N = \left(\frac{C}{R}\right) \times M = \frac{20}{10} \times 20 = 40$$ squirrels

3. A population's geographic range is the entire area occupied by the population whereas the distribution is a measure of how clumped individuals are within their geographic range.

✓ Concept Check 53.2

4. Population growth rate is the birth rate minus the death rate.

5. A low maximum per capita growth rate causes the population to grow more slowly than does a high maximum per capita growth rate.

6. In the exponential growth model, the population growth rate increases slowly at low populations sizes, but increases rapidly over time at high population sizes.

✓ Concept Check 53.3

7. For a Type I survivorship curve, individuals experience high survival throughout most of their life and then their survival declines sharply later in

life. For a Type III survivorship curve, individuals experience a sharp drop in survival early in life and then a slower decline throughout the rest of their life, with few individuals reaching adulthood.

8. *K*-selected species have low maximum per capita growth rates due to slow times to maturity, infrequent reproductive events, and few offspring per reproductive event. These characteristics result in populations that remain near the environment's carrying capacity. Examples include large mammals such as humans, horses, and elephants.

9. Characteristics of *r*-selected species

include a high maximum per capita growth rate due to rapid times to maturity, frequent reproductive events, and many offspring per reproductive event. These characteristics result in populations that exhibit large fluctuations in population sizes. Examples includes mice, insects, and frogs.

5. A

Module 54

✓ Concept Check 54.1

1. Density-independent factors cause declines in populations regardless of the size of the population. Examples include fires, droughts, tornadoes, and hurricanes.

2. Density-dependent factors cause stronger limits on population growth as the population increases in size. Examples include limited food, limited nesting sites, and limited open spaces on rocks on an ocean shoreline.

✓ Concept Check 54.2

3. The logistic model adds the parameter of carrying capacity (K), which causes population growth to slow as it approaches the carrying capacity of the environment.

4. For a population that begins small, there is initially a slow rate of growth that rapidly increases as it approaches one-half of the carrying capacity. Beyond one-half carrying capacity, the growth rate slows until it eventually becomes zero, when the population reaches the carrying capacity.

5. When a population exceeds its carrying capacity, death rates increase and birth rates decline, resulting in a rapid die-off of the

population.

1. D

2. C

3. D

4. A

5. B

Module 55

✓ Concept Check 55.1

1. Simpson's diversity index includes both species richness and species evenness.

2. The fundamental niche is the full suite of abiotic conditions that allow a species to survive, grow, and reproduce. The realized niche is the range of abiotic plus biotic conditions under which a species survives, grows, and reproduces. The realized niche is typically smaller than the fundamental niche.

3. A niche generalist lives under a wide range of abiotic and biotic conditions, whereas a niche specialist lives under a narrow range of abiotic and biotic conditions.

✓ Concept Check 55.2

4. When predators become abundant, there is a resulting decline in the prey

population and therefore an increase in the food, such as plants, normally consumed by the prey. With a decline in prey, the predator population has less food, so the predator population must decline. With fewer predators and more plants available, the prey population can then rebound, followed by a rebound in the predator population.

5. While parasites are species that live in or on another organism, only a subset of those parasites cause diseases in their hosts and these are categorized as pathogens.

6. When a predator or herbivore preferentially consumes the superior competitor, the inferior competitors

are better able to grow and reproduce.

✓ Concept Check 55.3

7. Beavers are keystone species because it only takes a few beavers to completely convert a flowing stream into a non-flowing pond. This flooding alters the environment by killing trees and favoring a new suite of plants and animals.

8. Direct effects occur between two species without any intermediate species involved. Indirect effects occur between two species with one or more intermediate species involved.

✓ Concept Check 55.4

9. As the plant community transitions from the initial composition of grasses and wildflowers to shrubs and then trees, it favors a change in the animal species that can live there, since each animal has a niche that must align with the plant species present.

10. Immediately after the major flood, we expect few—if any—species to be present. Over the next few weeks, different groups of algae and invertebrate animals will arrive, which will increase species richness over time.

Review Questions

1. A

2. B

3. C

4. D

5. A

Module 56

✓ Concept Check 56.1

1. Genetic diversity is the variety of genotypes present within a given population or species. Species diversity in the number of species and the evenness of their abundance.

2. Three processes that can affect the

genetic diversity of a species at the level of cells include independent assortment, recombination, and mutation.

3. The factors that can affect species diversity in an ecological community include habitat size, habitat diversity, keystone species, and disturbances.

✓ Concept Check 56.2

4. When sea otter populations were sharply reduced by hunting, their sea urchin prey became more abundant. The sea urchins consumed much of the kelp forest, which dramatically altered this important habitat that protects young coastal fish.

5. Increases in biodiversity, such as increases in the number of plant species of soil fungus species, can lead to increases in primary productivity in ecosystems.

6. Ecosystem resilience generally increases with increases in biodiversity.

✓ Concept Check 56.3

7. Economic benefits include natural products that humans use, such as lumber, fur, meat, crops, and medicines. They also include flood control, water filtration, recreational opportunities, and crop pollination.

8. Species richness is highest near the

equator and lowest near the poles.

9. Biodiversity hotspots are those areas with at least 1500 endemic plant species and experiencing at least 70% vegetation removal as a result of human activities.

Review Questions

1. A

2. B

3. C

4. D

5. A

Module 57

✓ Concept Check 57.1

1. Continental drift has caused continents to move across different latitudes, which has caused changes in the climate that any given continent has experienced and, as a result, changes in the ecosystems that can be supported on each continent.

2. With the receding glaciers of the most recent ice age, there were major shifts in the climate that caused the boundaries of ecosystems to shift northward as species of plants and animals shifted their distributions.

3. When an organism functions as a keystone species, such as the mastodons, its extinction can cause

widespread changes in the plants and animals that can persist, which can cause a dramatic change from one type of ecosystem (e.g., open habitats) to another (e.g., forested habitats).

✓ Concept Check 57.2

4. Using mammal fossils, we can compare the rate of extinction for mammals during the most recent 500 years with the rate during previous 500-year periods.

5. Amphibians have the highest percentage of threatened species, which is currently 40%.

6. The largest threat to species diversity is habitat loss.

7. The birds on islands have no evolutionary history with the exotic predators, so they often have no defenses against these predators.

✓ Concept Check 57.3

8. The two most common gases, nitrogen and oxygen, comprise 99% of the atmosphere, but they do not absorb and reemit infrared radiation from Earth so they cannot behave as greenhouse gases.

9. Greenhouse gases are naturally in the atmosphere and help to make Earth much warmer. Human activities have increased the concentrations of these gases, causing the planet to become even

warmer than would occur naturally.

10. A small decline in pH can make it harder for corals to obtain calcium carbonate from the water to build the skeleton of the coral reef.

✓ Concept Check 57.4

11. Terrestrial habitat protection has been increasing since the 1960s while marine habitat protection has been growing rapidly since the 1980s.

12. The key to the recovery of the condor was a combination of reduced harvesting, reduced poisoning, and a program of captive rearing that allowed reintroductions.

13. Following the decline in the

alligator population, the U.S. government first declared the alligator to be endangered, which stopped all hunting. Once the populations rebounded, the government allowed sustainable hunting by controlling how many alligators could be hunted each year.

AP® Biology Equations and Formulas

Statistical Analysis and Probability

Mean (*See pages 12, 20*)

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i$$

x ¯ = 1 n Σ i = 1 n x i

Mode = value that occurs most

frequently in a data set (*See pages 12, 21*)

Median = middle value that separates the greater and lesser halves of a data set (*See pages 12, 20*)

Mean = sum of all data points divided by number of data points (*See pages 12, 20*)

Range = value obtained by subtracting the smallest observation (sample minimum) from the greatest (sample maximum) (*See page 22*)

Standard Error of the Mean (*See page 24*)

S E x ¯ = s n $SE_{\bar{x}} = \frac{s}{\sqrt{n}}$

Standard Deviation (*See pages 22–24, 28*)

s = Σ (x i − x ¯ 2) n − 1

$$s = \sqrt{\frac{\sum\left(x_i - \bar{x}^2\right)}{n-1}}$$

Chi-Square (*See pages 374–376, 388–389*)

χ 2 = Σ (o − e) 2 e $\chi^2 = \sum \frac{(o-e)^2}{e}$

x ¯ = sample mean $\bar{x}$ = sample mean

n = sample size

s = sample standard deviation (i.e., the sample-based estimate of the standard deviation of the population)

o = observed results

e = expected results

$\sum$ = sum of all

Degrees of freedom are equal to the number of distinct possible outcomes minus one.

Chi-Square Table (*See page 375*)

P-value	Degrees of Freedom
[illegible]	
[illegible]	
[illegible]	

Laws of Probability (*See pages 372–373, 386–388*)

If A and B are mutually exclusive, then:

P (A or B) = P (A) + P (B)

$$P(\text{A or B}) = P(\text{A}) + P(\text{B})$$

If A and B are independent, then:

P (A and B) = P (A) × P (B)

$$P(\text{A and B}) = P(\text{A}) \times P(\text{B})$$

Hardy–Weinberg Equations (*See* *pages 607–611*)

p 2 + 2 p q + q 2 = 1 $p^2 + 2pq + q^2 = 1$

p + q = 1 $p + q = 1$

p = frequency of allele 1 in a population

q = frequency of allele 2 in a population

Metric Prefixes

Prefix	Symbol	Factor
giga	G	10^9
mega	M	10^6
kilo	k	10^3
deci	d	10^{-1}
centi	c	10^{-2}
milli	m	10^{-3}
micro	μ	10^{-6}
nano	n	10^{-9}
pico	p	10^{-12}

Rate and Growth

Rate (*See page 198*)

d Y d t $\frac{dY}{dt}$

Population Growth (*See pages 755–757, 774*)

d N d t = B – D $\frac{dN}{dt} = B - D$

Exponential Growth (*See pages 757–760, 775*)

d N d t = r max N $\frac{dN}{dt} = r_{\max} N$

Logistic Growth (*See pages 768–769, 775–778*)

d N d t = r max N (K – N K)

$\frac{dN}{dt} = r_{\max} N \left(\frac{K-N}{K} \right)$

dY = amount of change

dt = change in time

B = birth rate

D = death rate

N = population size

K = carrying capacity

rmax$r_{\max}$ = maximum per capita growth rate of population

Simpson's Diversity Index (*See pages 779–782*)

Diversity index = 1 − Σ (n N) 2

$$\text{Diversity index} = 1 - \sum \left(\frac{n}{N}\right)^2$$

n = total number of organisms of a particular species

N = total number of organisms of all species

Water Potential (Ψ) (Ψ), Solute Potential, and pH

Water Potential (*See pages 160–162*)

$\Psi = \Psi p + \Psi S$ $\Psi = \Psi_p + \Psi_S$

$\Psi p =$ pressure potential

$\Psi_p =$ pressure potential

$\Psi S =$ solute potential

$\Psi_S =$ solute potential

The water potential will be equal to the solute potential of a solution in an open container because the pressure potential of the solution in an open

container is zero.

The Solute Potential of a Solution (*See pages 161–162*)

$\Psi S = -iCRT$ $\Psi_S = -iCRT$

i = ionization constant (1.0 for sucrose because sucrose does not ionize in water)

C = molar concentration

R = pressure constant (R = 0.0831 liter bars/mole K)

T = temperature in Kelvin (°C + 273)

pH (*See pages 48–49*)

$pH = -\log [H+]$ $pH = -\log [H^+]$

Surface Area and Volume (*See pages 121–122, 126*)

Surface Area of a Sphere

$SA = 4\pi r2$ $SA = 4\pi r^2$

Surface Area of a Rectangular Solid

$SA = 2lh + 2lw + 2wh$

$SA = 2lh + 2lw + 2wh$

Surface Area of a Cylinder

$SA = 2\pi rh + 2\pi r2$

$SA = 2\pi rh + 2\pi r^2$

Volume of a Sphere

V = 4 3 π r 3 $V = \frac{4}{3}\pi r^3$

Volume of a Rectangular Solid

V = l w h $V = lwh$

Volume of a Cylinder

V = π r 2 h $V = \pi r^2 h$

Volume of a Cube

V = s 3 $V = s^3$

Extended Descriptions

The front cover of the book is titled, Biology for the A P Course by James Morris, Domenic Castignetti, John Lepri, and Rick Relyea and published by b f w publishers

A textbox shows a dedication to Jen Pfannerstill

A textbox shows a letter to the reader

An annotated reproduction of a textbook page illustrates the organization, scope, and pacing of the

course

An annotated page reproduction illustrates the features of the book to aid in study and review

An annotated page reproduction shows an example of an A P (registered trademark) exam tip and practice questions

Annotated text shows how the book provides A P (registered trademark) opportunities at the unit and full book level

Annotated text shows how the book uses in-text explanations and boxes to build skills

Annotated text shows two examples of tutorials and explains how they are used

Annotated text shows how

illustrations, photos, and graphs are used for visual analysis in the text

Annotated text shows how visual synthesis figures are used

Figure 28.9 A pedigree for human colorblindness, an X-linked trait
Figure 28.10 A pedigree for a Y-linked gene
Figure 28.11 Crossing over between linked genes
Figure 28.12 Linked genes in fruit flies
Figure 28.13 The organelles of egg

and sperm cells

Figure 28.14 A pedigree for a human disease caused by a mutant allele in mitochondria

A pedigree chart shows inheritance of an unknown disorder across three generations

A 2 by 2 Punnett square shows the offspring obtained from a cross between homozygous dominant and homozygous recessive pea plants

A 2 by 2 Punnett square shows the offspring obtained from a cross between a heterozygous purple flower and a homozygous white flower

A 2 by 2 Punnett square shows the offspring obtained from a cross between two heterozygous seeds

An illustration and an equation show

the probability of obtaining a specific sequence of seeds

Figure 29.2 Phenotypic plasticity in gray treefrog tadpoles

A bar graph plots wood frog relative growth under different conditions

Figure 29.6 Different corn strains in a range of nitrogen environments

Figure 29.8 Phenotypic trade-offs in goldfish swimming when raised at cold and warm temperature

Four graphs plot (a) year versus mass at weaning, (b) mass at weaning versus year, (c) mass at weaning versus year, and (d) breed versus mass at weaning

A double bar graph plots indole produced versus leaf area consumed for two genotypes

Visual Synthesis 5.1 THE COMBINED EFFECTS OF GENES AND THE ENVIRONMENT IN DETERMINING PHENOTYPES

Figure 30.1 Tay-Sachs disease

Figure 30.4 Nondisjunction

Figure 30.5 Trisomy 21

Figure 30.6 Phenotypic effects of have an extra or missing sex chromosome

A pedigree chart shows the inheritance of the ability to taste P T C across three generations

A line graph shows blood phenylalanine levels compared to weeks after injection

An illustration shows a parental cell and four gamete cells

A pedigree chart shows the inheritance of fur color across three

generations

A 2 by 2 Punnett square shows the offspring produced from a cross between two cats with genotype capital M small m

Figure 31.1 Nucleotides

Figure 38.10 Recombinant DNA

Figure 38.12 CRISPR

A figure shows four electrophoresis gels labeled a through d on which D N A has been separated

A horizontal electrophoresis gel shows band patterns from hair at a crime scene and four suspects

A horizontal electrophoresis gel shows band patterns from a mother bird and six chicks

Figure 39.2 Viral shapes

Figure 39.4 Lytic and lysogenic pathways

Figure 39.5 Pandemics in history

Figure 39.6 HIV infection

Figure 39.9 Viruses in the oceans

Visual Synthesis 6.2 Viruses

A table shows the amino acids specified by the genetic code

A figure shows a piece of a gene with exons and introns

A figure shows four electrophoresis gels labeled a through d. On each gel, a size standard is run in one lane and a P C R product is run in another

A figure shows interactions that take place in high blood sugar versus low blood sugar conditions

Two graphs compare bacterial abundance with and without the presence of a phage for both wildtype and mutant bacteria

Figure 40.3 Vertebrate body plan

Figure 40.4 Evolutionary relationships among primates

Figure 40.5 The tree of life

An illustration compares ancestral bacteria that have been frozen and then grown versus bacteria that have been grown in a medium with limiting amounts of glucose

A graph plots growth of descendant strains relative to ancestral strains by generation to demonstrate evolution between two strains of bacteria

Figure 41.5 A desert plant adapted for a dry climate

Figure 41.6 Convergent evolution

Figure 41.7 Stabilizing selection

Figure 41.8 Directional selection

Figure 41.9 Disruptive selection

Figure 41.10 Artificial selection

A graph plots percent oil content against generation for two species of corn, one of which was artificially selected for high oil content and the other of which was artificially selected for low oil content

Four pairs of graphs labeled a through d show pre-selection and post-selection frequencies of a trait

A bar graph plots mean percentage of pure red in feathers for captive versus wild cardinals

Figure 42.2 Mutation and recombination

Figure 42.3 Mutation rate

A figure shows how to carry out replica plating

A figure shows how to use replica

plating to test the effects of an antibiotic

A figure shows how the Lederbergs grew a culture of antibiotic-resistant bacteria from an antibiotic-resistant colony identified using replica plating

Figure 42.4 Common mutations in populations

A figure illustrates how gel electrophoresis works and how it can be used to detect genetic variation

An electrophoresis gel contains small rectangular cutouts at the top numbered one through eight that mark eight lanes, each of which contains bands for comparison to determine whether each sample had an S S, F F, or F S genotype

A stacked bar graph plots the

percentage of fish that are completely plated, partially plated, and unplated against year

Two electrophoresis gels compare protein bands for the hemoglobin protein for Atlantic cod from the east coast of Norway versus the west coast of Norway

Figure 43.2 Natural selection

Figure 43.4 Genetic drift

disruptive selection

Figure 47.11 Speciation by hybridization in sunflowers

Figure 47.12 Speciation by hybridization in Darwin's finches

A graph shows the number of generations produced by two types of European corn borer moths per year

A visual synthesis titled speciation shows genetic drift. A visual synthesis titled speciation shows natural selection

Figure 48.1 Birds, crocodiles, and their extinct relatives

Figure 48.3 Mass extinctions

A photo of a striated rock is depicted next to a graph that shows how much iridium in parts per billion can be found in certain different layers of

rock from the Paleogene and Cretaceous Periods

A photo shows a striated structure quartz crystal, an example of shocked quartz, above a map of Central America along with a satellite image of a crater where this type of quartz is found

Figure 48.4 The supercontinent Pangaea

Figure 48.5 Growth of the human population over time

Figure 48.8 Biodiversity at risk

A graph plots deer population against year to show how the white-tailed deer population in the United State varies over time

Figure 49.4 The spread of Ug99

Figure 49.5 Centers of origin for crops

A graph plots proportion surviving to metamorphosis against salinity level in an aquarium for tadpoles from high salinity and low salinity egg sources

An illustration shows Stanley Miller’s apparatus designed to simulate Earth's early atmosphere

Figure 50.3 Spontaneous polymerization of nucleotides

Figure 50.4 A liposome

Figure 50.5 A timeline of the history of Earth and life

A graph illustrates the products of reactions of hydrogen cyanide and ammonia over 8 days as adenine and hydrogen cyanide are produced

A phylogenetic tree shows the relationships between Q, R, S, T, and

U

Four different phylogenetic trees labeled a through d show the relationships between Q, R, S, T, and U

Four phylogenetic trees labeled a through d show the relationships between species J, L, M, K, and N

A graph plots average number of tomatoes per plant against year

Four bar graphs plot the proportion of plants infected against the origin of white campion

A phylogenetic tree shows the relationships of 8 lizard species

Figure 51.1 The hierarchy of ecological systems

Figure 51.2 Phototropism in plants

Figure 51.6 Innate courtship behavior

Two figures show how researchers demonstrated that female digger wasps use landmark cues to find their nests

A figure compares the movement of bacteria in a beaker containing a capillary tube with water versus a beaker containing a capillary tube with glucose

A graph plots average number of attempts to eat shrimp against time to illustrate the response of stickleback fish to the sight of brine shrimp in a glass tube that prevented the fish from eating the shrimp

Figure 52.2 Metabolic rates of mammals and body size

Figure 52.5 Trophic levels

Figure 52.6 A simplified food web

Figure 52.7 The carbon cycle

A figure shows interactions between a primary producer, two primary consumers, a secondary consumer, and a tertiary consumer

A visual synthesis figure is titled thermoregulation in an endotherm and illustrates how a rock squirrel responds to changing temperatures. A visual synthesis figure is titled thermoregulation in an ectotherm and illustrates how a zebra-tailed lizard responds to changing temperatures. A diagram shows the movement of carbon dioxide in the terrestrial carbon cycle. A figure shows the marine carbon cycle

Figure 53.2 Geographic range

Figure 53.3 Population distributions

Figure 53.4 Changes in population size

A graph shows changes in the population of Japan from 1900 to 2005

Figure 53.5 Exponential growth model

A graph shows the growth of rabbit populations with italicized r end italics subscript max equals 0.5 and 1.5

Figure 53.6 Survivorship curves

Figure 54.3 Density-independent factors in population growth

Figure 54.4 Density-dependent growth in two species of Paramecium

Figure 54.5 Logistic growth model

Figure 54.6 Overshoot and die-off in reindeer

Figure 54.7 Human population growth in the United States

A graph plots population size against time for an animal species and indicates the carrying capacity

A graph plots population size against days to show the increase in population size of italicized Euglena gracilis end italics over time

A graph plots population size against days to show the increase in population size of italicized Euglena gracilis end italics over time

A graph plots population size against time to produce an exponential curve accompanied by descriptive text

A graph plots population size against time to show a logistic curve that is labeled to indicate what is happening at different parts of the curve

A graph plots population size against

days to illustrate the initial growth rate in a logistic growth curve

A graph showing a logistic curve is accompanied by text explaining what happens during the period of rapid growth in the middle of the curve

A graph showing a logistic curve is accompanied by text explaining what happens as growth slows at the end of the curve

Figure 56.10 Effects of fungal species richness on ecosystems

Figure 56.11 The effects of plant species richness on the stability of a grassland ecosystem

Figure 56.12 Species richness patterns in vascular plants

Figure 56.13 Species richness patterns in mammals

Figure 56.14 Biodiversity hotspots

A graph plots number of species over time with the removal of species X and with the removal of species Y

A bar graph plots biomass difference between experimental plots and control plots for a variety of experimental treatments

A graph plots number of species of amphibians and reptiles against island area for seven West Indies islands

Figure 57.1 Disrupted ecosystems due to continental drift
Figure 57.2 Expanding species distributions after glaciers receded
Figure 57.5 The gain and loss of forested habitats around the world
Figure 57.8 The overharvesting of cod
Figure 57.10 The greenhouse effect
Figure 57.11 The Keeling curve of increasing CO2mathml alt text in the atmosphere
Figure 57.12 Global warming around the world
Two graphs compare percent change in net calcification in control and experimental groups of a reef with part a showing the effects of increased p H and part b showing the effects of decreased p H

Figure 57.13 Protecting habitats

A graph plots number of extinctions and the human population by year

A graph plots proportion of high-quality nest sites occupied by italicized P. major end italics against average December temperature

A graph plots Simpson's diversity index against temperature

A graph plots average population count of harbor seals by year to produce a population growth curve

A bar graph compares the numbers of four species observed within a reserve in 2000 versus 2020

A graph plots percent resistance of italicized Streptococcus pneumonia end italics against two antibiotics over a ten-year period

A graph plots number of butterflies in patch A by year

A figure shows a food web above a table listing the species and the number of each species in the sampling area

A figure shows a plant releasing and absorbing water

A figure shows four sets of two molecules each, which are connected by hydrogen bonds and labeled a through d

A vertical piece of membrane with extracellular space on the left and intracellular space on the right has three regions through which different molecules pass

A figure shows two vertical strands of two nucleotides each with hydrogen

bonds connecting the upper pair of nucleotides together and the lower pair of nucleotides together. Some bonds are labeled as A, B, C, or D

A figure shows interactions of molecules that regulate the cell cycle

A figure shows a close-up of the upper part of an intestinal cell

A figure shows a food web including ten species that live in Redwood National Forest

A graph plots D N A content against time to show how D N A content changes throughout the cell cycle

A flowchart shows the steps of glycolysis

A graph plots molecular abundance against time to show how levels of glucose, pyruvate, fructose 6-

phosphate, glucose 6-phosphate, and fructose 1, 6-bisphosphate change over 90 minutes

A figure shows how the body responds to changes in glucose concentration to maintain the set point of glucose in the blood

Four graphs labeled a through d plot level of insulin and glucagon against glucose level in the blood

A figure shows the gametes produced from a parental cell with 2 italicized n end italics equals 4

A figure shows a chemical reaction in which water is added to a molecule to form two products

A figure compares gene expression with and without oxidative stress

A figure shows four possible trophic

relationships labeled a through d
A phylogenetic tree shows the relationships between seven species labeled J through P
A figure shows a pedigree for italicized Eleutherodactylus coqui end italics frogs
A figure shows how chorismate can be used to produce tryptophan, phenylalanine, and tyrosine
A graph plots phenylalanine against tryptophan using a box-and-whisker plot
A graph compares the ability of two lineages of italicized Drosophila melanogaster end italics to defend themselves against parasitoid wasps over 8 generations
A graph plots amount of italicized g a

l 1 end italics m R N A transcripts and galactokinase proteins per cell by time and documents the effects of adding and removing galactose

A graph plots insect abundance per plant by sampling date to compare patterns in experimental gardens with different numbers of plant genotypes

A figure shows the structure and function of the electron transport chain used in the light reaction of photosynthesis

A graph plots average height against average diameter to illustrate the relationship between these characteristics of Douglas fir trees

A graph shows an example of how to plot points on a graph and look for a

pattern

A graph shows how to set up an x y graph and label the axes

A graph plots average distance from nearest neighbor against elevation for fireweed flowers as an example of a histogram

A graph illustrates how to produce a bar graph showing two characteristics for each of four wildflower species and using error bars of plus or minus 2 standard error

A two-part graph shows histograms, plotting frequency of upper respiratory symptoms in part a and frequency of lower respiratory symptoms in part b

A graph plots average water temperature against month to

illustrate how to use a line graph
A graph shows how to use a dual y graph, which is a graph with two vertical axes
A graph plots number of bacteria against temperature to produce a graph that can be compared to a log scale graph presenting the same data
A graph plots number of bacteria (log scale) against temperature to indicate how log scales work
An example of a pie chart shows percentages of five tree species in a plot of land
An example pie chart without percentages listed shows greenhouse emissions from various sources
A graph shows an example of a box and whisker graph

A graph plots richness against habitat to illustrate the use of a box and whisker graph to show the distribution of rotifer species richness in different habitats

A graph plots number of COVID-19 cases against date to illustrate an example of an area graph

A graph plots pace of aging against biological aging to illustrate a scatter plot graph

The back cover of the book is titled, Biology for the A P Course by James Morris, Domenic Castignetti, John Lepri, and Rick Relyea and published by b f w publishers

Extended description for: The front cover of the book is titled, Biology for the A P Course by James Morris, Domenic Castignetti, John Lepri, and Rick Relyea and published by b f w publishers

The front cover shows a lynx crouching and looking at the camera. The page has the title of the book at the top which reads, Biology for the A P Course. The name of the authors at the bottom of the page read, James Morris, Domenic Castignetti, John Lepri, and Rick Relyea.

Text at the bottom reads, A P is a trademark registered by the College Board, which is not affiliated with, and does not endorse, this product.

Return to The front cover of the book is titled, Biology for the A P Course by James Morris, Domenic Castignetti, John Lepri, and Rick Relyea and published by b f w publishers

Extended description for: An illustration shows a page to fill details of the student to whom the book is issued

THIS BOOK IS THE PROPERTY OF:

STATE _____
PROVINCE _____
COUNTY _____
PARISH _____
SCHOOL DISTRICT _____
OTHER _____

Book No. _____
Enter information in spaces to the left as instructed

ISSUED TO	*Year Used*	*CONDITION*	
		ISSUED	*RETURNED*

PUPILS to whom this textbook is issued must not write on any page or mark any part of it in any way, consumable textbooks excepted.

1. Teachers should see that the pupil's name is clearly written in ink in the spaces above in every book issued.
2. The following terms should be used in recording the condition of the book: New; Good; Fair; Poor; Bad.

The heading reads, This Book Is The Property Of, followed by blanks to enter information in spaces to the left as instructed. The blanks are for State, Province, Country, Parish, School District, Other, and Book Number. Below a blank table shows nine rows and four columns. The column headers are Issued to, year used, Issued, and Returned. The third and fourth columns, Issued and Returned, are collectively labeled, Condition.

Return to An illustration shows a page to fill details of the student to whom the book is issued.

A page from the book, Biology for the A P Course, shows the information about the cover page

The page on the left shows a lynx crouching and looking at the camera.

On the right, the text under the heading, About the Cover, reads: A Canada lynx (Lynx canadensis) with piercing green eyes seems to be looking directly at you on our cover. The image draws you in, inviting you to ask and answer questions about how life works. The Canada lynx is a visually stunning cat, with its distinctive ear tufts and long hair hanging down from its lower cheeks. Its hind limbs are longer than its front limbs, so its back slopes downward as it hunts in northern forests of North America, searching for prey. Just from looking at it you can tell itâ€™s a predator, with its sharp eyes, strong limbs, lean body, powerful muscles, and retractable

claws. Predation has shaped its form and function over many generations. It has also shaped its preyâ€”the snowshoe hare (Lepus americanus).

The interaction of the Canada lynx and snowshoe hare echoes and highlights the themes you will encounter throughout your A P Biology class. Evolution has influenced the form and function of all organisms on Earth, and thatâ€™s particularly clear when looking at predators and prey. The two have evolved in lockstep, driving each otherâ€™s adaptations. Underpinning evolution is the idea of Information Storage and Transmission, which allows organisms to function and pass

on traits from generation to generation. None of this would be possible without Energetics â€” a source of energy fueling the entire process and the ability of organisms to harness this energy to carry out their functions. And the lynx and hare donâ€™t exist in isolation, but instead are part of an ecosystem that functions as a whole. Thus, Systems Interactions, whether at the scale of a forest or a cell, provides a way to put all the pieces together.

While you will approach biology class by class and module by module, donâ €™t forget that these themes are inseparable in nature. The lynx on the cover is there to remind you of the

four Big Ideas of A P Biology and how they work together to sustain life.

Extended description for: A textbox shows a dedication to Jen Pfannerstill

Ken Canning/Getty Images

The text reads as follows: To Jen

Pfannerstill. All A P (registered trademark) Biology students need a friend. The course is stimulating and will challenge you to learn new and amazing things. Along that path, a steady, smart, knowledgeable, and concerned friend can guide and motivate you to do your best. Jen Pfannerstill was a best friend to A P (registered trademark) Biology, as her students and colleagues will testify. More than two decades of her fierce commitment to the A P (registered trademark) Biology curriculum, the exam, and biology students serve as an example of what a teacher can be. Unfortunately, we lost this dear friend too soon. We dedicate this work to her friendship and commitment to all

things A P (registered trademark) Biology. We hope that you never feel alone in your A P (registered trademark) journey.

Return to A textbox shows a dedication to Jen Pfannerstill

Extended description for: A textbox shows a letter to the reader

Congratulations!
The decision to take AP® Biology requires curiosity, courage, and commitment. And now you are about to embark on a dramatic learning adventure. The subject is no less than how all of life works. Along the way you will undoubtedly face challenges. You will also be rewarded with a greater understanding of the world around you and a set of skills that will serve you whether or not you take additional biology courses in the future. You will emerge from this course in a better position to understand issues related to biological sciences that affect you as a person and as a citizen.

We hope that you will find this book an invaluable companion. We wrote this book to provide you with all the tools you need to succeed on the exam and gain confidence with the subject matter. We have divided the book's units into modules that are shorter than typical book chapters. This will help you pace your reading. Make sure you take the time to go over the Concept Check questions at the end of each section. Check your answers at the back of the book and then review any material you have not yet mastered. At the end of the module, Review Questions will also help you determine which concepts need more study. You will be able to practice for the exam all year with hundreds of AP® Practice Questions located at the end of modules and units, and at the end of the book you'll find a cumulative AP® Practice Exam, just like the actual exam in size and scope.

Visual analysis is an important component of the course. We have selected photos and created images that enhance your experience and bring the subject matter to life. Notice the detailed captions on figures and text discussions of figures, designed to help you follow and understand the key ideas of AP® Biology.

Pay close attention to the numerous AP® Exam Tips scattered throughout the modules. These tips, written by former chief readers for the AP® Biology Exam, will give you an inside track on content you need to know, and on key strategies for answering exam questions. Also make sure to read all the boxed material carefully. Analyzing Statistics and Data boxes walk you through critical math and statistics tools and provide additional practice. Practicing Science boxes are designed to help you develop your ability to use the critical science practice of questions and methods. Finally, make sure to read and review the four tutorials to solidify your understanding of statistics, probability, population growth, and graphing.

Good luck with your year!

James Morris *Domenic Castignetti* *John Lepri* *Rick Relyea*

A circle at the upper left shows a photo of the head of a lynx. The text

reads as follows:

Congratulations!

The decision to take A P (registered trademark) Biology requires curiosity, courage, and commitment. And now you are about to embark on a dramatic learning adventure. The subject is no less than how all of life works. Along the way you will undoubtedly face challenges. You will also be rewarded with a greater understanding of the world around you and a set of skills that will serve you whether or not you take additional biology classes in the future. You will emerge from this course in a better position to

understand issues related to biological sciences that affect you as a person and as a citizen.

We hope that you will find this book an invaluable companion. We wrote this book to provide you with all the tools you need to succeed on the exam and gain confidence with the subject matter. We have divided the book's units into modules that are shorter than typical book chapters. This will help you pace your reading. Make sure you take the time to go over the Concept Check questions at the end of each section. Check your answers at the back of the book and then review any material you have not yet mastered. At the end of the

module, Review Questions will also help you determine which concepts need more study. You will be able to practice for the exam all year with hundreds of A P (registered trademark) Practice Questions located at the ends of modules and units, and at the end of the book you'll find a full A P (registered trademark) Practice Exam, just like the actual exam in size and scope.

Visual analysis is an important component of the course. We have selected photos and created images that enhance your experience and bring the subject matter to life. Notice the detailed captions on figures and text discussions of figures, designed

to help you follow and understand the key ideas of A P (registered trademark) Biology.

Pay close attention to the numerous A P (registered trademark) Exam Tips scattered throughout the modules. These tips, written by former chief readers for the A P (registered trademark) Biology Exam, will give you an inside track on content you need to know, and on key strategies for answering exam questions. Also make sure to read all the boxed material carefully. Analyzing Statistics and Data boxes walk you through critical math and statistical tools and provide additional practice. “Practicing Science” boxes are

designed to help you develop your ability to use the critical science practice of questions and methods. Finally, make sure to read and review the four tutorials to solidify your understanding of statistics, probability, population growth, and graphing.

Good luck with your year!

James Morris, Domenic Castignetti, John Lepri, Rick Relyea.

Extended description for: An annotated reproduction of a textbook page illustrates the organization, scope, and pacing of the course

Your book matches the course both in organization and scope. Module content is built around concepts specific to your course and the AP® Biology Exam.

Content is scaffolded so each new topic is introduced at the right time so you have all the necessary foundations. **Modules** contain manageable chunks of material for you to pace yourself and review as you study each new topic.

Unit 1

Chemistry of Life

Unit 1 0 1 2 3 4 5

Module 0

Introduction

LEARNING GOALS LG 0.1 Four Big Ideas form a fundamental basis for understanding biology.
LG 0.2 Scientific inquiry is a deliberate way of asking and answering questions about nature.

The ears of the snowshoe hare (*Lepus americanus*) stand tall as it listens carefully and its nose twitches as it smells the air for the scent of its predator, the Canada lynx (*Lynx canadensis*). At the same time, the lynx uses its keen eyesight, its sense of smell, and its ears to locate its prey, the hare. Having spotted the hare, the lynx quietly and deliberately moves toward it, slowly closing the distance between itself and the hare. Then, suddenly, the lynx springs upon the hare and the chase for life and food begins.

The activities of predator and prey depend on a number of key processes that they both possess. For instance, both hare and lynx are strong and swift runners. Both are exquisitely adapted to sense their habitats, be aware of danger,

understanding of the **gene,** which is the unit of heredity, and the **genome,** which is all of the genetic information that an organism contains. This information is helping us come up with new ways of fighting disease in humans, other animals, and plants. It is also helping us understand how different groups of organisms have evolved and how endangered species might be saved. Many new biological frontiers have opened up in recent decades, while others are still waiting to be explored. For example, researchers are only just beginning to understand how bacteria in our digestive system affect our health and well-being. Other researchers are looking at how the temperature and acidity of seawater affect the ecology of coral reefs.

LEARNING GOALS
- LG 1.1 Matter and energy govern the properties of life.
- LG 1.2 The atom is the fundamental unit of matter.
- LG 1.3 Atoms combine to form molecules linked by chemical bonds.
- LG 1.4 Carbon is the backbone of organic molecules.

Module 1 Summary

LG 1.1 Matter and energy govern the properties of life.

- All organisms are made up matter and require energy to sustain life. Page 26
- Organisms obtain matter from other organisms and the environment, and matter therefore moves in a cycle, with the same atoms used and reused. Page 26

Every module is organized around two to four **learning goals.** These learning goals are revisited in module **summaries.** Use these goals to help you organize new information and to review what you have learned.

The **Four Big Ideas of AP® Biology** are emphasized in every module to keep you focused on content that matters.

PREP FOR THE AP® EXAM

FOCUS ON THE BIG IDEAS

ENERGETICS: Look for the elements that make up all organisms, and the way in which organisms exchange these elements with the environment.

PREP FOR THE AP® EXAM

REVISIT THE BIG IDEAS

ENERGETICS: Using the content in this module, **identify** the key elements that all organisms obtain from the environment and exchange with the environment.

End of module multiple-choice **Review Questions** help you further assess your strengths and weaknesses with module content.

Review Questions

1. Using the periodic table shown in Figure 1.4, identify which atom is most likely to have properties similar to nitrogen.
   (A) Oxygen (O) (C) Lead (Pb)
   (B) Bismuth (Bi) (D) Carbon (C)
2. The element sodium (Na) has an atomic number of 11 and an atomic mass of 23. Calculate the number of protons and neutrons in Na.
   (A) 11 protons and 11 neutrons
   (B) 11 protons and 10 neutrons
   (C) 11 protons and 12 neutrons
   (D) 10 protons and 13 neutrons
3. Which type of bond is formed between a sodium ion and a chloride ion?
   (A) Ionic (C) Polar covalent bond
   (B) Neutral (D) Nonpolar covalent bond
4. Which type of bond is formed between two oxygen atoms?
   (A) Ionic (C) Polar covalent bond
   (B) Neutral (D) Nonpolar covalent bond
5. When two molecules undergo a chemical reaction, they
   (A) lose atoms.
   (B) keep the same bonding partners that they had as reactants.
   (C) establish new bonding partners.
   (D) incorporate atoms from the air and water as well as from the reactants.
6. Proteins, nucleic acids, and carbohydrates are all
   (A) information molecules.
   (B) signaling molecules.
   (C) polymers made up of repeating subunits.
   (D) monomers that combine to form polymers.
7. Two organic molecules that store energy for use by the cell are
   (A) carbohydrates and nucleic acids.
   (B) carbohydrates and lipids.
   (C) proteins and nucleic acids.
   (D) nucleic acids and lipids.

✓ Concept Check

3. **Describe** the components of an atom.
4. **Describe** how the rows and columns of the periodic table of the elements are organized.
5. **Identify** what the superscripts of ^{14}H and ^{15}N signify.
6. **Calculate** how many additional electrons would be needed to fill the outer energy level of C.
7. **Identify** the location of the electrons around an atom that have the most energy associated with them.

At the end of each section, **Concept Check** questions give you the opportunity to check your understanding of key concepts. Because you'll find the answers at the back of the book, you will know right away which concepts need extra attention.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A box at the upper left reads, Learning goals with four learning

goals listed vertically to the right as follows: L G 1.1 Matter and energy govern the properties of life; L G 1.2, The atom is the fundamental unit of matter; L G 1.3 Atoms combine to form molecules linked by chemical bonds; and L G 1.4 Carbon is the backbone of organic molecules. A box below reads, Module 1 Summary, L G 1.1. Matter and energy govern the properties of life above two bullet points. The first bullet point reads, All organisms are made up matter and require energy to sustain life. Page 26. The second bullet point reads, Organisms obtain matter from other organisms and the environment, and matter therefore moves in a cycle, with the same atoms used and

reused. Page 26. An annotation pointing to the learning goals and Module 1 summary reads, Every module is organized around two to four learning goals. These learning goals are revisited in module summaries. Use these goals to help you organize new information and to review what you have learned. To the right are two boxes. The first box is titled Focus on the big ideas, and the circular label includes text reading, Prep for the A P (registered trademark) Exam. Text in the box reads, Energetics: Look for the elements that make up all organisms and the way in which organisms exchange these elements with the environment. An annotation to this

box reads, The Four Big Ideas of A P (registered trademark) Biology are emphasized to keep you focused on content that matters. A second box below is titled Revisit the Big Ideas and has a similar circular label with text reading, Prep for the A P (registered trademark) Exam. Text in the second box reads, Energetics: Using the content in this module, identify the key elements that all organisms obtain from the environment and exchange with the environment. A section at the lower left is titled Review Questions and includes seven multiple choice questions with an annotation that reads, End of module multiple-choice Review Questions help you further

assess your strengths and weaknesses with module content. A box that overlaps the upper right corner of the box with the questions has a check mark and then the word Concept Check above statements numbered 3 to 7 that provide instructions to work with the module material. An annotation to this box reads, At the end of each section, Concept Check questions give you the opportunity to check your understanding of key concepts. Because you'll find the answers at the back of the book you will know right away which concepts need extra attention.

PREP FOR THE AP® EXAM

AP® EXAM TIP

Nonpolar and polar covalent bonds govern many of the properties of organic molecules. Knowing these concepts will help you understand how these molecules function, which will help you succeed on the AP® Biology Exam.

AP® Exam Tips are scattered throughout the modules to help you focus on key content you should know for the exam.

Module 14

AP® Practice Questions

PREP FOR THE AP® EXAM

Questions 3 and 4 refer to the following information.

Glucose-6-phosphate dehydrogenase (G6PD) is an enzyme that converts a substrate, glucose-6-phosphate, to a product, 6-phosphogluconolactone. A scientist added 0.1 nanomole (nmol) of G6PD to a test tube containing 25 nmol of glucose-6-phosphate (the substrate) and measured the accumulation of 6-phosphogluconolactone (the product) over 7 hours. The data that the scientist obtained are shown in the graph.

3. Based on the data provided, what is the best estimate of the rate at which G6PD converts substrate to product in this experiment?
(A) 0.1 nmol/min
(B) 2.0 nmol/min
(C) 3.6 nmol/min
(D) 5.0 nmol/min

4. Which provides the best explanation for why no further product accumulates after 5 hours?
(A) All of the G6PD enzyme has been consumed and is no longer able to catalyze the reaction.
(B) The reaction releases energy as heat, which causes the G6PD enzyme to become denatured.
(C) All of the substrate has been consumed, so the reaction can no longer proceed.
(D) The concentration of substrate becomes too high and inhibits the reaction.

At the end of each module, AP® Practice Questions, which are structured like the questions you'll see on the exam, help you build confidence as you sharpen your test-taking skills.

Section 2: Free-Response Question

Pepsin is a digestive enzyme in animal stomachs that helps to digest, or break down, protein in the diet. A researcher tested the ability of 1 mg of pepsin to digest the protein albumin across a range of pH values. The researcher mixed six solutions, each with a different pH level, listed in the table below. Each solution was divided among 10 tubes. The researcher then added 1 mg of pepsin and 3000 mg of albumin to each tube. At the end of a 5-hour incubation period, the researcher measured the amount of albumin that had been digested in each tube. The mean amount of albumin digested at each pH and the standard error of the mean are shown in the table below.

pH	Mean albumin digested (mg)	Standard error (mg)
1	677	180
2	2880	0
3	2880	120
4	2105	170
5	1146	130
6	132	60

(a) **Draw** an appropriately labeled graph of pepsin activity across pH values, including error bars.
(b) **Identify** the pH at which pepsin activity is highest.
(c) Do you see evidence to support a claim that pepsin activity is different at pH = 3 and pH = 4? **Make a claim** and **Justify** your reasoning based on the data provided.
(d) **Calculate** the percent activity of pepsin at pH = 5, relative to the maximum activity observed in the experiment. You may ignore the standard error for this calculation.
(e) **Make a claim** that would explain the observed activity of pepsin at pH = 6.

Extended description for: Annotated text shows how the book provides A P (registered trademark) opportunities at the unit and full book level

A page is titled Unit 1, A P (registered trademark) Practice Questions and

includes an icon reading, Prep for the A P (registered trademark) exam. The page shows three multiple choice questions. An annotation to the page reads, At the end of each unit, a comprehensive set of Unit A P (registered trademark) Practice Questions addresses content across the unit. Another page at the lower right is accompanied by an annotation that reads, A Cumulative A P (registered trademark) Practice Exam at the end of the book matches the actual A P (registered trademark) Biology Exam in structure and scope.

Return to Annotated text shows how the book provides A P (registered trademark) opportunities at the unit

and full book level

Extended description for: Annotated text shows how the book uses in-text explanations and boxes to build skills

A page reproduction at the top is labeled Analyzing Statistics and Data

next to a play symbol and includes an icon reading, Prep for the A P (registered trademark) exam. Beneath the header, text reads Averages and provides an introductory paragraph above an example titled Practice the skill. An annotation to this page reads, Throughout the text, Analyzing Statistics and Data boxes walk through key statistical tools and techniques to help you practice and learn in context. Note the “play” icon, which signifies an associated video. An overlapping page below is titled Your Turn and shows a problem to solve. An annotation reads, Each Analyzing Statistics and Data box includes a Your Turn problem, which provides an opportunity for you to

practice the relevant tools and gain confidence. A page below is titled Practicing Science 9.1 and shows the icon reading, Prep for the A P (registered trademark) exam. The heading inside the box reads, Do proteins move in the plasma membrane? The box includes background, hypothesis, and experiment and results sections with an illustration. An annotation reads, Practicing Science boxes present and evaluate key experiments in the history of biology. Each box addresses the science practice of questions and methods with an in-depth look at research questions, experimental design, and results. Understanding questions and methods in the context

of actual scientific work provides you with a better foundation for applying this science practice. A small box at the lower right is titled A P (registered trademark) practice question. An annotation to this box reads, Each box concludes with a free-response style A P (registered trademark) Practice Question that asks you to evaluate experimental design and methods or a proposed extension to the researcher's work.

Return to Annotated text shows how the book uses in-text explanations and boxes to build skills

Extended description for: Annotated text shows two examples of tutorials and explains how they are used

Tutorial 1: Statistics

PREP FOR THE AP® EXAM

Scientific evidence rarely hinges on the result of a single experiment, measurement, or observation. As we discussed in Module 0, any scientific claim must be backed up by data from multiple subjects across multiple repetitions of the same experimental process or multiple observations. It is the accumulation of evidence from many independent sources, all pointing in the same direction, that lends weight to a scientific hypothesis until eventually it becomes a theory.

This means that any statement of a number—arm can carry 10 times their weight; a human cell can divide in 24 hours—is actually a statement of many numbers. How do scientists determine what number will represent all of their experimental results? And how do scientists succinctly describe all of the individual data points? Statistics is a field that helps scientists to organize, analyze, and see trends in data. In this tutorial, we will discuss several statistical tools that help us understand and interpret data. We will start with a quick look at the issue of precision in reporting calculations.

Significant Figures

When reporting any recorded data or quantitative conclusions, you should use appropriate precision. For example, if you measure something and say it is 2 meters tall, does that mean it is exactly 2 meters or perhaps 2.05 meters or even 2.10 meters? Significant figures indicate the precision of a measurement. Significant figures are numbers that carry meaning. For example, 2 meters has just one significant figure because it has only one digit. By contrast, 2.03 has three significant figures. The more significant figures, the more precise the measurement.

In general, all nonzero numbers (1, 2, 3, and so on) are significant. Zeros between other numbers are also significant. For example, as we noted, the number 2.03 has three significant figures. Leading zeros (zeros that are located to the left of another number) are not significant. The number 0.02 has only one significant figure. Trailing zeros (zeros located to the right of another number) are also not significant, except in numbers with a decimal point. For example, the number 2.10 has three significant figures.

When doing calculations, significant figures in a final answer are determined by the number that is the least precise in your dataset. However, do not round intermediate values when you perform calculations; only round your final answer. For example, let's say you are asked to calculate the area of a rectangle (width (*w*) × height (*h*), with $w = 4.33$ feet and $h = 2$ feet. The answer is

Average: Mean, Median, and Mode

When scientists make observations or do an experiment, they gather results and collect data. The direct observations and measurements that have not been organized, processed, or interpreted are known as raw data. For example, a doctor collects all kinds of raw data about your health, such as height, weight, body temperature, breathing rate, heart rate, and blood pressure. You may give a blood or urine sample so that the concentrations of various substances can be measured. Or you may spit into a vial so that a DNA sample can be obtained to look for common genetic variants associated with disease. The data collected by physicians are all types of raw data.

After scientists collect raw data, they often process the data in some way in order to make sense of it. One way to process it involves determining the average of all of the measurements. Determining the average takes all of the individual pieces of data and provides a single, representative number. In this section, we look at several different ways to calculate the average.

Mean

The first type and most common type of average is called the **mean**. Given a set of values, the **mean** is obtained by adding all of the values in the dataset and dividing by the number of values in the dataset, which is indicated by *n*.

Example: In the dataset of nine values, 5, 9, 4, 6, 3, 1, 5, 9, 1, 9, the mean is determined by adding all of the values ($5 + 9 + 4 +$

Longer **Tutorials** presented throughout the book provide comprehensive explanations of statistics, growth equations, probability, and graphing skills used throughout the course. The tutorials are a great review tool. Tutorials also point you to relevant Analyzing Statistics and Data boxes for additional practice.

Tutorial 2: Probability

PREP FOR THE AP® EXAM

Gregor Mendel's pea plant crosses provided the world with new knowledge about the presence and functioning of genes. The purebred parental generation (P_1) crosses refuted the commonly believed blending hypothesis, an idea that phenotypes or traits of offspring were the average traits of the parents, and instead revealed the existence of dominant and recessive alleles. The crosses of the offspring of those parents ($P_1 \times F_1$) contributed more evidence to the concepts of dominant and recessive alleles by producing plants with traits that were not seen in the original P_1 crosses.

These experiments laid the groundwork for more complicated genetic studies and still serve as a foundation for understanding basic hereditary patterns. Not only do these pea plant crosses represent a clear example of heredity, they also provide an excellent opportunity to understand probability and its role in predicting the outcome of events. In this tutorial, we will discuss probability and its role in Mendelian genetics.

The homozygous dominant parent's gametes and the homozygous recessive parent's gametes produce four offspring combinations. In this case, they are all heterozygous *Aa*.

The probability of a homozygous dominant offspring, *A:A*, is 0; it never happens. The same can be said for a homozygous recessive offspring, *aa*. However, the probability of homozygous offspring is $\frac{1}{2}$; it always occurs.

This example replicates the findings of Mendel's initial purebred P_1 crosses. The F_1 generation inherits the *A* allele from one parent and the *a* allele from the other parent, resulting in a heterozygous genotype, *Aa*.

Your Turn

Mendel discovered that the alleles for purple flowers were dominant to white flowers in his pea plants. What is the probability of each type of offspring, in terms of genotype and phenotype, when crossing a heterozygous purple flower plant with a white flower plant?

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A page at the upper left is titled Tutorial 1: Statistics. It contains content related to statistics. The

major subheadings shown read, Significant Figures and Average: Mean, Median, and Mode. An overlapping page at the lower right is labeled Tutorial 2: Probability. Both pages have the icon reading, Prep for the A P (registered trademark) exam. An annotation pointing to both tutorials reads, Longer Tutorials presented throughout the book provide comprehensive explanations of statistics, growth equations, probability, and graphing skills used throughout the course. The tutorials are a great review tool. Tutorials also point you to relevant Analyzing Statistics and Data boxes for additional practice.

Return to Annotated text shows two examples of tutorials and explains how they are used

Extended description for: Annotated text shows how illustrations, photos, and graphs are used for visual analysis in the text

At the upper left, a photo shows a layer of lipid with many bubbles of varying sizes above it. Text below

reads, Figure 1.15 Lipids. When oil, which is a lipid, is mixed in water, it forms droplets to minimize its contact with water. Oil, like all lipids, is hydrophobic. An annotation to this box reads, Figures and graphs integrate seamlessly with text discussions. A graph below plots average heart rate against cups of coffee and shows five points with error bars. Text below reads, Figure 0.8. Error bars. An error bar represents a range of values within which the true value is likely to be. This graph shows the relationship between caffeine consumption and resting heart rate. It plots the average resting heart rate of groups of people who consumed 0, 1, 2, 3, or 4 cups of

coffee, with error bars giving an indication of the uncertainty of the data. An annotation to this graph reads, Data in graphs are always accompanied by a careful walk-through. A figure to the right shows a close-up of an animal cell using a micrograph and an illustration of a Golgi apparatus. Text reads, Figure 7.5 The Golgi apparatus. The Golgi apparatus is the next stop for proteins and lipids produced in the E R. It further modifies these proteins and lipids; it sorts and targets them to other organelles, the cell membrane, or the cell exterior; and it adds sugars to proteins and lipids. Vesicles transfer molecules from the E R to the Golgi apparatus, within the Golgi

apparatus, and from the Golgi apparatus to their final destinations. An annotation reads, Illustrations make complex structures and concepts easier to visualize.

Return to Annotated text shows how illustrations, photos, and graphs are used for visual analysis in the text

Extended description for: Annotated text shows how visual synthesis figures are used

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Special Visual Synthesis figures throughout the book present integrated concepts across each unit.

A figure is titled Visual Synthesis 1.1 The four big ideas of A P (registered trademark) biology. An introduction is provided, then the four big ideas are illustrated. There are four large

boxes accompanied by illustrations and photos. The boxes are labeled evolution, energetics, systems interactions, and information storage and transmission. The main illustration focuses on a lynx chasing a hare and other illustrations of lynx and hares, including hares with different color fur at different times of year, hares eating, a hare with two young hares, and a lynx with a young lynx. Each box provides information about the specified topic. A callout to the visual synthesis figure reads, Special Visual Synthesis figures throughout the book present integrated concepts across each unit.

visual synthesis figures are used

Annotated text provides information about the e-book

The front page of the book, showing a lynx crouching on a rock, is depicted on three devices. From left to right, these are a tablet, a computer, and a phone. An annotation to this picture reads, The interactive, mobile-read e-book allows you to read and reference the text when you are online and offline. All offline highlights and

notes sync when you connect to the internet.

Return to A page from the book, Biology for the A P Course, shows the information about the cover page

Annotated text provides information about the homework system

The book title is illustrated at the top of the page above text reading, Upcoming assignments and events, there are no upcoming assignments or events, and above a box labeled student resources with links depicted below to access resources and help. A vertical menu bar on the left shows

the following options from top to bottom: activities and due dates, resources, grades, profile, and courses. Annotations show close-ups of resources available. One is a genetics activity, and one is a video. An annotation to the homework example reads, The online homework system helps you learn with targeted feedback based on common misconceptions. Students who use this system find that it significantly improves their understanding and helps them build essential foundations.

Return to Annotated text provides information about the homework system

Extended description for: Figure 0.5 Scientific Inquiry

The flowchart starts at a textbox labeled exploration, which reads, “Make observations, Ask questions, Approach the world with curiosity, Read the scientific literature.” An arrow points to the next textbox labeled investigation. There are five

steps under investigation that read as follows, “Formulate hypotheses, Make predictions, Do experiments or make new observations, Gather and interpret data, Establish a theory.” Text accompanying an arrow from “Gather and interpret data” to “Formulate hypotheses” reads, “If results are not consistent, revise or reject the hypothesis. If results are consistent over many experiments and explain a wide variety of observations, hypotheses become a theory.” An arrow from investigation points to the next textbox labeled communication, which reads, “Discuss experiments, Share results, Publish papers, Participate in conferences, Inform policy, Address

problems." An arrow points back to the textbox labeled exploration and the cycle repeats.

Return to Figure 0.5 Scientific Inquiry

Extended description for: Figure 0.8 Error bars

The horizontal axis represents cups of coffee and ranges from 0 to 4, in increments of 1. The vertical axis represents average heart rate in beats per minute and ranges from 60 to 100, in increments of 10. The data points with corresponding vertical error bar

are as follows: (0, 60) with error bar ranging from 58 to 62; (1, 68) with error bar ranging from 62 to 72; (2, 79) with error bar ranging from 74 to 81; (3, 89) with error bar ranging from 81 to 96; and (4, 100) with error bar ranging from 95 to 105. The first data point (0, 60) is labeled, average heart rate of students after 0 cups of coffee.

Return to Figure 0.8 Error bars

Extended description for: Visual Synthesis 1.1 The Four Big Ideas Of AP® Biology

The first part shows a white coat snowshoe hare sitting in a snowy terrain during winters and a brown coat snowshoe hare standing on its hind limbs in a forest during summers. Corresponding text reads,

Evolution investigates changes in the genetic makeup of a population over time. Through the process of natural selection, species become adapted to their environments. For example, ancestors of the snowshoe hare and Canada lynx evolved to have adaptations that increased their survival and reproduction. This includes the hare's ability to change coat color with the seasons.

The second part shows a view of the Earth, labeled Biosphere; a snowy forest, labeled Ecosystem; a snowshoe hare and a Canada lynx, labeled Community; few snowshoe hares, labeled Population; a single snowshoe hare, labeled Individual;

and a cross-section of an animal cell, labeled Cell. An arrow from the community points to an illustration of a Canada lynx running behind a snowshoe hare to catch it. Corresponding text reads, Systems Interactions examines the way the components of biological systems interact with and affect one another. A system can be as small as a cell or as large as the biosphere. New properties of biological systems emerge through the interactions of organisms such as Canada lynx and snowshoe hares, and through interactions between species and their environment.

The third part shows a white coat

snowshoe hare eating leaves. Corresponding text reads, Energetics considers the processes used by cells and organisms to exchange matter and energy with their environment. For example, Canada lynx and showshoe hares acquire, store, and use the energy and matter obtained from the environment to maintain homeostasis, grow, and reproduce.

The fourth part shows a Canada lynx sitting with its offspring in a snowy terrain and a snowshoe hare with its two offspring emerging out of their burrow in snow. Corresponding text reads, Information Storage and Transmission explores how information is stored, used, and

transmitted by cells and organisms. Using information stored in D N A and through experience, the Canada lynx knows how to hunt its prey and the snowshoe hare knows how to evade its predator. These behaviors are transmitted to offspring through D N A and through the process of learning.

Extended description for: Figure 1.3 Energy levels for hydrogen and carbon

The hydrogen atom shows one electron in the orbit surrounding the nucleus. The carbon atom shows two concentric circles or orbits surrounding the nucleus. The inner orbit has two electrons and the outer orbit has four electrons. An accompanying text reads, “In this simplified diagram, the electron

energy levels are depicted as circles and the electrons that occupy them as dots. The cloud in the center is the nucleus.”

Return to Figure 1.3 Energy levels for hydrogen and carbon

Extended description for: Figure 1.4 The periodic table of the elements

The periodic table shows seven rows and eighteen columns, with the symbol and atomic number given in each entry.

Elements of column 1 are Hydrogen, H, 1, Lithium, L i, 3, Sodium, N a, 11,

Potassium, K, 19, Rubidium, R b, 37, Caesium, C s, 55, and Francium, F r, 87.

Elements of column 2 are Beryllium, B e, 4, Magnesium, M g, 12, Calcium, C a, 20, Strontium, S r, 38, Barium, B a, 56, and Radium, R a, 88.

Elements of column 3 are Scandium, S c, 21, Yttrium, Y, 39, lanthanides 57 to 71, and actinides 89 to 103. The lanthanides, elements from atomic number 57 to 71, are as follows: They are Lanthanum, L a, 57, Cerium, C e, 58, Praseodymium, P r, 59, Neodymium, N d, 60, Promethium, P m, 61, Samarium, S m, 62, Europium, E u, 63, Gadolinium, G d, 64, Terbium,

T b, 65, Dysprosium, D y, 66, Holmium, H o, 67, Erbium, E r, 68, Thulium, T m, 69, Ytterbium, Y b, 70, Lutetium, L u, 71. The actinides, elements from atomic number 89-103, are as follows: Actinium, A c, 89, Thorium, T h, 90, Protactinium, P a, 91, Uranium, U, p2, Neptunium, N p, 93, Plutonium, P u, 94, Americium, A m, 95, Curium, C m, 96, Berkelium, B k, 97, Californium, C f, 98, Einsteinium, E s, 99, Fermium, F m, 100, Mendelevium, M d, 101, Nobelium, N o, 102, Lawrencium, L r, 103.

Elements of column 4 are Titanium, T i, 22, Zirconium, Z r, 40, Hafnium, H f, 72, and Rutherfordium, R f, 104.

Elements of column 5 are Vanadium, V, 23, Niobium, N b, 41, Tantalum, Ta, 73, and Dubnium, D b, 105.

Elements of column 6 are Chromium, C r, 24, Molybdenum, M o, 42, Tungsten, W, 74, and Seaborgium, S g, 106.

Elements of column 7 are Manganese, M n, 25, Technetium, T c, 43, Rhenium, R e, 75, and Bohrium, B h, 107.

Elements of column 8 are Iron, F e, 26, Ruthenium, R u, 44, Osmium, O s, 76, and Hassium, H s, 108.

Elements of column 9 are Cobalt, C o, 27, Rhodium, R h, 45, Iridium, I r, 77,

and Meitnerium, M t, 109.

Elements of column 10 are Nickel, N i, 28, Palladium, P d, 46, Platinum, P t, 78, and Darmstadtium, D s, 110.

Elements of column 11 are Copper, C u, 29, Silver, A g, 47, Gold, A u, 79, and Roentgenium, R g, 111.

Elements of column 12 are Zinc, Z n, 30, Cadmium, C d, 48, Mercury, H g, 80, and Copernicium, C n, 112.

Elements of column 13 are Boron, B, 5, Aluminum, A l, 13, Gallium, G a, 31, Indium, I n, 49, Thallium, T l, 81, and Nihonium, N h, 113.

Elements of column 14 are Carbon, C,

6, Silicon, S i, 14, Germanium, G e, 32, Tin, S n, 50, Lead, P b, 82, and Flerovium, F l, 114.

Elements of column 15 are Nitrogen, N, 7, Phosphorous, P, 15, Arsenic, A s, 33, Antimony, S b, 51, Bismuth, B i, 83, and Moscovium, M c, 115.

Elements of column 16 are Oxygen, O, 8, Sulfur, S, 16, Selenium, S e, 34, Tellurium, T e, 52, Polonium, P o, 84, and Livermorium, L v, 116.

Elements of column 17 are Fluorine, F, 9, 19.00, Chlorine, C l, 17, Bromine, B r, 35, Iodine, I, 53, Astatine, A t, 85, and Tennessine, T s, 117.

Elements of column 18 are Helium, H

e, 2, Neon, N e, 10, Argon, A r, 18, Krypton, K r, 36, Xenon, X e, 54, Radon, R n, 86, and Oganesson, O g, 118.

The elements found in human cells in various levels of abundance are as follows:

High: Hydrogen, Carbon, Nitrogen, Phosphorous, and Oxygen; Low: Sodium, Magnesium, Potassium, Calcium, Sulfur, and Chlorine; Trace: Vanadium, Chromium, Manganese, Iron, Cobalt, Nickel, Copper, Zinc, Molybdenum, Fluorine, Iodine, and Selenium. All other elements are rare or not present in human cells.

The elements found in human cells in

various categories are: High: Hydrogen, Carbon, Nitrogen, Phosphorous, and Oxygen; Low: Sodium, Magnesium, Potassium, Calcium, Sulfur, and Chlorine; Trace: Vanadium, Chromium, Manganese, Iron, Cobalt, Nickel, Copper, Zinc, Molybdenum, Fluorine, Iodine, and Selenium. All other elements are not present in human cells.

Return to Figure 1.4 The periodic table of the elements

Extended description for: Figure 1.5 Number of electrons across row 2 of the periodic table

Each atom shows two energy levels. Lithium: two electrons in the inner energy level and one in the outer energy level. Beryllium: two electrons in the inner energy level and two in the outer energy level. Boron: two electrons in the inner energy level and three in the outer energy level. Carbon: two electrons in the inner

energy level and four in the outer energy level. Nitrogen: two electrons in the inner energy level and five in the outer energy level. Oxygen: two electrons in the inner energy level and six in the outer energy level. Fluorine: two electrons in the inner energy level and seven in the outer energy level. Neon: two electrons in the inner energy level and eight in the outer energy level.

Return to Figure 1.5 Number of electrons across row 2 of the periodic table

Extended description for: Figure 1.6 Covalent bonds

Each atom shows one energy level. Carbon atoms have four blue electrons in their outer level with the nuclei labeled, C; and fluorine atoms have eight red electrons in their outer level with the nuclei labeled, N. After forming covalent bonds, the nuclei of the four fluorine atoms is labeled, F,

and their outer levels show one blue electron and seven red. The carbon atom is at the center of the four fluoride atoms, with its outer level overlapping with the fluoride atoms and showing four red and four blue electrons at the points of overlap.

Return to Figure 1.6 Covalent bonds

Extended description for: Figure 1.8 A polar covalent bond

Chemical formula H_2O

Space-filling model

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The space-filling model shows a red sphere labeled, O, with two smaller blue spheres labeled, H, attached to it on top left and top right, respectively. Both H atoms are labeled, delta positive, and the O atom is labeled, delta negative.

Return to Figure 1.8 A polar covalent bond

Extended description for: Figure. 1.9 An ionic bond

Part a: The electron shell diagrams of sodium (N a) and chlorine (C l) atoms shows each with three energy levels. The first two energy levels of each contain two and eight electrons, respectively. The outer energy level of chlorine contains eight electrons, while sodium's outer level contains

only one. An arrow from a single electron in sodium's outer energy level points to an electron on chlorine's outer energy level. Text reads: "In sodium chloride (salt), sodium loses an electron and becomes positively charged, and chlorine gains an electron and becomes negatively charged." The sodium ion has two energy levels and a positive charge. Chorine has three energy levels and a negative charge. These two ions then join together to form a molecule of sodium chloride, whose chemical formula is N a C l. Text reads: "The two atoms are now attracted to each other."

Part b: An illustration shows a

graduated beaker containing sodium chloride solution. An arrow from the beaker points to a space filling model of sodium chloride. Water molecules around its outside illustrate that the solution is a mixture of water (H subscript 2 O) and sodium chloride (N a C l). An arrow from the space filling model points to two sets of space filling models. The models show a positively charged sodium ion and a negatively charged chlorine ion surrounded by four water molecules, each. The water molecules surrounding the sodium ion have a partial negative charge, and those around the chlorine ion have a partial positive charge. The oxygen in water is attracted to the sodium and the

hydrogen in water is attracted to the chorine. Text reads: “Sodium chloride (N a C l) dissolves in solution because the sodium ions (N a superscript positive) and chloride ions (C l superscript negative) each become surrounded by water molecules.”

Return to Figure. 1.9 An ionic bond

Extended description for: Figure 1.10 A chemical reaction

The chemical reaction reads, 2 H subscript 2 (hydrogen gas) plus O subscript 2 (oxygen gas) results in 2 H subscript 2 O (water). The structure of a hydrogen molecule shows two single bonded hydrogen atoms. The

structure of oxygen molecule shows two double bonded oxygen atoms. The water molecule has a central oxygen atom single bonded to two hydrogen atoms.

Return to Figure 1.10 A chemical reaction

Extended description for: Figure 1.11 Approximate percentages by dry mass of chemical elements found in human cells

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The data in the chart are as follows: Carbon (C), 52 percent; Oxygen (O), 21.5 percent; Nitrogen (N), 8.5 percent; Hydrogen (H), 7.5 percent; Calcium (C a), 4.5 percent; Phosphorous (P), 3 percent; Sulfur (S), Potassium (K), Sodium (N a), Chlorine (C l), and Magnesium (M g), 2 percent; and Other, 1 percent.

Return to Figure 1.11 Approximate percentages by dry mass of chemical elements found in human cells

Extended description for: An illustration shows the structural formula of the sugar fructose

The structure is a vertical chain of six, single-bonded carbon atoms, each with one or more atoms bound to the left and/or right.

Each row of the chain, left to right, is as follows.

1. C, H subscript 2, O, H

2. C double bond O.

3. H, O, C. H.

4. H, C, O H.

5. H, C, O H.

6. C, H subscript 2, O, H.

Return to An illustration shows the structural formula of the sugar fructose

Extended description for: Figure 2.1 Hydrogen bonds

A text reads, A hydrogen bond forms between two water molecules when the partial positive charge of a hydrogen atom is attracted to the partial negative charge of an oxygen atom.

The oxygen atom in the water molecule is a semicircle on top of an inverted triangle, like a snow cone, that has a partial negative polarity. The hydrogen atoms are semicircles on the remaining two sides of the triangle and have partial positive polarity. A red dashed line indicates the bond between the oxygen of one water molecule and the hydrogen of another water molecule. Eleven water molecules are bound into two strings of either five or six molecules.

Return to Figure 2.1 Hydrogen bonds

Extended description for: Figure 2.3 Ice, water, and steam

Photos top to bottom: Ralph Lee Hopkins/Getty Images; DIESCHERL Reinhard/hemisphicture.com/Getty Images; Louise Murray, Getty Images
Morris, et al., *Biology for the AP® Course*, 1e. © 2022 BFW High School Publishers

Three space-filling models of different phases of water

accompanied by a representative image are as follows.

(a) Ice; solid water: Hydrogen bonds between the water molecules form interlocking hexagons. Several layers of molecules are visible, all sharing the same orderly, hexagonal pattern. There are no water molecules without bonds. Accompanied photo shows a penguin on an ice shelf.

(b) Liquid water: Hydrogen bonds occur between some water molecules, but not all. Here, there are chains of eleven, five, and two molecules of water in addition to many molecules without bonds. Accompanied photo shows a reef off

the coast of a sandy beach.

(c) Steam; gaseous water: There are no hydrogen bonds between the water molecules. Instead, gray smears extend from each molecule to indicate their rapid movement. Accompanied photo shows fog over the treetops of a forest.

Return to Figure 2.3 Ice, water, and steam

Extended description for: Figure 2.4 Water as a solvent

Morris, et al., *Biology for the AP ® Course*, 1e, © 2022 BFW High School Publishers

The nitrogen atom of the ammonia molecule has a partial negative charge and a bond to the hydrogen atom of a water molecule. The three

hydrogen atoms of the ammonia molecule are each attracted to the partial negative charge of the oxygen atom on a neighboring water molecule.

Return to Figure 2.4 Water as a solvent

Extended description for: Figure 2.6 The pH scale

The scale ranges from 0, the most acidic, to 14, the most basic. A vertical double-sided arrow depicts

the relative proportions of hydrogen and hydroxide ions at each range: Basic [H superscript plus] is less than [O H superscript negative]; Neutral [H superscript plus] is equal to [O H superscript minus]; and Acidic [H superscript plus] is greater than [O H superscript minus].

The liquids on the scale (and their approximate p H) are as follows:

Sodium hydroxide (13.5).

Household bleach (12.5).

Ammonia (11).

Seawater (8.25).

Human blood (7.5).

Pure water (7).

Apple juice (3.5).

Lemon juice (2).

Stomach fluid (1.5).

Return to Figure 2.6 The pH scale

Extended description for: Figure 2.7 A dehydration synthesis reaction

The reagents are H O, single bond, red circle, single bond, red circle, single bond, red circle, single bond, H and H O, single bond, red circle, H. These combine to generate water (H, single bond, O, single bond, H) and H O, single bond, red circle, single bond, red circle, single bond, red circle, single bond, red circle, single

bond, H. The final single bond is the new covalent bond.

Return to Figure 2.7 A dehydration synthesis reaction

Extended description for: Figure 2.8 The dehydration synthesis of a monoglyceride

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The reagents glycerol and a fatty acid are in a chemical equilibrium with a monoglyceride and water.

The molecular structures are as follows:

Glycerol - O H (blue), single bond to a

C, which has two single bonds up and two single bonds down, each end in an O H group.

Fatty acid - R, single bond, C, with a double bond up to O, and a single bond right to a blue O H group.

Monoglyceride - The same basic structure of the glycerol, except what was the O H group at the top is now O, single bond, C, with a double bond up, O and a single bond, R.

Return to Figure 2.8 The dehydration synthesis of a monoglyceride

Extended description for: Figure 2.9 A hydrolysis reaction

The reagents are water (H, single bond, O, single bond, H) and the molecule H O, single bond, red circle, single bond, red circle, single bond, red circle, single bond, red circle, single bond, H.

A branching arrow extends from the reagents to the reaction products. The

reaction products are the molecule H O, single bond, red circle, single bond, red circle, single bond, red circle, single bond, H (obtained from the water) and the molecule H O (obtained from the water), single bond, red circle, single bond, H.

Return to Figure 2.9 A hydrolysis reaction

Extended description for: Figure 2.10 The hydrolysis of a two-unit sugar

Morris, et al., *Biology for the AP®* *Course*, 1e, © 2022 BFW High School Publishers

A two-unit sugar is attacked by a molecule of water to yield (a single arrow pointing right) two, one-unit sugars.

The two-unit sugar is composed of two carbon hexagonal rings. The first carbon of each ring has a single bond to an O atom that binds the two units

together. The third carbon of each ring has a single bond to an O H group. Arrows from each H of a molecule of water point to the single bonds on either side of the O of the two-unit sugar.

Both resulting one-unit sugar hexagons still have the O H group on their third carbons and now have an O H group on the first carbon. The O on the first sugar gains an H ion from the water and the second sugar gains the remaining O H from the water.

Return to Figure 2.10 The hydrolysis of a two-unit sugar

Extended description for: Figure 3.1 Glucose and fructose

Both molecules are six-carbon chains with a double bond to an O and six hydroxyl groups. Both molecules are

presented vertically with the first carbon, C 1, at the top. The groups bound to each C will be presented left to right.

Glucose: H, down right, C 1, double bond up right, O; H, C 2, O H; H O, C 3, H; H, C 4, O H; H, C 5, O H; H, C 6, O H; H.

Fructose: H; H, C 1, O H; C 2, double bond O; H O, C 3, H; H, C 4, O H; H, C 5, O H; H, C 6, O H; H.

Return to Figure 3.1 Glucose and fructose

Extended description for: Figure 3.2 Linear and ring forms of glucose

Linear glucose is a six-carbon open ring. C 1 has a double bond to oxygen and a single bond to hydrogen. C 1 has a dark wedge bond to C 2, thick single bond, C3, dark wedge bond, C 4, single bond, C 5, single bond up to C 6 and single bond to O H. A red dashed arrow points from the O of the

hydroxyl group to C 1.

Arrows point to and from linear glucose and cyclic glucose.

Cyclic glucose has a single bond from the O to C 1, which has a dark wedge bond to hydrogen and a gray wedge bond to a hydroxyl group.

Return to Figure 3.2 Linear and ring forms of glucose

Extended description for: Figure 3.3 Ribose and deoxyribose

Ribose

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Deoxyribose

Both structures are pentagonal rings with four carbons and an oxygen atom.

Ribose: O; C 1 with a single bond up

to C H subscript 2, O H, and single bond down to H; C 2 has a single bond up H and single bond down O H; C 3 has a single bond up to an H and a single bond down to a highlighted O H; and C 4 has a single bond up to an O H and a single bond down to an H.

Deoxyribose: Only differs from ribose at C 3, whose single bond down is to an H.

Return to Figure 3.3 Ribose and deoxyribose

Extended description for: Figure 3.4 Glycosidic bonds

Two cyclical glucose molecules combine to form a glycosidic bond and release a molecule of water.

The glycosidic bond forms between C 1 of the left glucose and C 4 of the right glucose.

Return to Figure 3.4 Glycosidic bonds

Extended description for: Figure 3.6 Triacylglycerol and its components

Glycerol: A three-carbon and three hydroxyl chain. H O, single bond, C H subscript 2, C with single bond up H and single bond down O H, single bond, C H subscript 2, and O H.

Fatty acid: A chain of sixteen carbon atoms and a double-bonded O. C H subscript 3, followed by fourteen C H subscript 2, together compose the hydrocarbon chain. The sixteenth carbon has a double bond up to an O and a single bond to a hydroxyl group, which together are the carboxyl group.

Triacylglycerol: Triacylglycerols are formed by the addition of three fatty acid chains to glycerol. A glycerol molecule forms the backbone where each glycerol carbon and O H group connects to the carboxyl group C of a fatty acid. There is a three C backbone. The structure of the first and third groups are C H subscript 2,

O, C, double bond O, ten C H subscript 2, C H subscript 3; the structure of the central group is C H, O, C, double bond O, ten C H subscript 2, C H subscript 3.

Return to Figure 3.6 Triacylglycerol and its components

Extended description for: Figure 3.7 Saturated and unsaturated fatty acids

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A. Saturated fatty acid. The structure is horizontal from start to finish. H O, single bond, C, double bond up O, ten C H subscript 2, C H subscript 3.

B. Unsaturated fatty acid. The structure is horizontal until the double bond, at which point it bends down to the right. H O, C, double bond up O, four C H subscript 2, C H, double bond, C, H, five C H subscript 2, C H subscript 3.

Return to Figure 3.7 Saturated and unsaturated fatty acids

Extended description for: Figure 3.8 Van der Waals forces

Morris, et al., *Biology for the AP^{®} Course*, 1e, © 2022 BFW High School Publishers

The illustration shows the presence and equilibrium of Van der Waals forces between three fatty acid chains (each with 17 C hydrocarbon chains) in three steps.

Step 1. The first chain is completely horizontal and has positive polarity indicated at three locations above the chain (the same side as the double bond O) and negative polarity at three places below. The far end of the second chain is angled up toward the first chain, and the carboxyl end is angled down. The carboxyl end of the third chain is angled up, close to the carboxyl end of the second, while the far end is angled away.

Step 2. The first and second fatty acid chains are parallel. The negative polarity on the bottom of the chain at three places is attracted to and aligned with, the oppositely charged polarity on the top of the second chain. Three black dots between the polarity symbols are identified as the Van der Waals force. The carboxyl group of the third chain is close to the carboxyl group of the third, but the far end is angled away.

Step 3. All three chains are parallel to each other. The upper parts of the three chains have a positive polarity that is attracted to the negative polarity of the chain above it, resulting in three locations with Van

der Waals forces between each pair of fatty acids.

Return to Figure 3.8 Van der Waals forces

Extended description for: Figure 3.9 Cholesterol

The structure of cholesterol shows a cyclohexanol sharing a bond with a cyclohexene. A methyl group is bound to one of the shared carbons. A cyclohexane shares a bond with the cyclohexene and another bond with a cyclopentane. A methyl group extends

from a C shared by the cyclohexane and a cyclopentane. C 2 of the cyclopentane has a single bond to a six-carbon chain, which has a methyl group at C 1 and C 5.

Return to Figure 3.9 Cholesterol

Extended description for: Figure 3.10 Phospholipids

A phospholipid is shaped like a sphere with a straight leg and a bent leg. The bilayer is composed of two

inverted planes of phospholipids.

The round hydrophilic head of a phospholipid is composed of phosphate and glycerol. Each leg is a hydrophobic tail; the straight leg is a saturated fatty acid and the bent leg an unsaturated fatty acid.

Starting at the top of the hydrophilic head, the structure is as follows:

R, single bond, O, P with a double bond left O, a single bond right, O minus, and single bond down, O, single bond, C H subscript 2, single bond left, C H, single bond left, C H subscript 2. From the C H and the second C H subscript 2 extend single bond, O, single bond C with a double

bond up to O and a single bond to a fatty acid. The C H connects the unsaturated fatty acid and the C H subscript 2 connects the saturated fatty acid.

Return to Figure 3.10 Phospholipids

Extended description for: An illustration shows the structures of phosphatidic acid and glycogen

Phosphatidic Acid: The structure has a three-carbon vertical backbone where the first carbon is bound to a phosphate group, and the second and third carbons are each bound to a

fatty acid chain: O, single bond, C, double-bonded to oxygen and a single bond to 16 C H subscript 2, and C H subscript 3.

Glycogen: The structure contains eight glucose molecules in two rows. The first row contains three molecules, the last of which is bound to the central glucose in a row of five. In addition to the glycosidic bond at C 4 with the previous glucose, the third glucose in the first row has a glycosidic bond to the methyl group bound to the fifth carbon of the third glucose in the second chain of five glucose molecules.

Return to An illustration shows the

structures of phosphatidic acid and glycogen

Extended description for: Figure 4.2 Amino acid structure

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

(a) Amino acid structure. A central carbon with four single bonds: H up; R group down; amino group left, H

subscript 2 N; and carboxyl group right. The amino group is N, H subscript 2. The carboxyl group is C, double bond O, and single bond O H.

(b) Ionized amino acid. Same basic structure but the amino group is N superscript plus, H subscript 3, and the carboxyl group is C, double bond O, and O superscript minus.

Return to Figure 4.2 Amino acid structure

Extended description for: Figure 4.3 Structures of the 20 amino acids commonly found in proteins

Morris, et al., *Biology for the AP® Course*, 1e, © 2023 BFW High School Publishers

The amino acid backbone does not change from superscript plus, H

subscript 3, N, single bond, C H, single bond, C O O superscript minus where the R group extends from the central (alpha) carbon. There is one exception in the special amino acids that will be described. Assume single bonds between atoms unless stated otherwise.

Part 1. Hydrophobic amino acid R groups.

Alanine (A l a, A): C H subscript 3.

Valine (V a l, V): C H with two single bonds, each to a C H subscript 3.

Leucine (L e u, L): C H subscript 2, C H with two single bonds, each to a C H subscript 3.

Isoleucine (I l e, I): C H that branches to a single bond, C H subscript 3, and single bond C H subscript 2, C H subscript 3.

Methionine (M e t, M): C H subscript 2, C H subscript 2, S, C H subscript 3.

Phenylalanine (P h e, F): C H subscript 2, C (start 6 C ring), double bond, C, C, double bond, C, C, double bond, C (end 6 C ring).

Tryptophan (T r p, W): C H subscript 2, C (start pentameric ring) double bond, C, N H, C (start hexameric ring), double bond, C (end pentameric ring), C, double bond, C, C, double bond, C (end pentameric ring). The pentamer and hexamer

share a carbon-carbon double bond.

Tyrosine (T y r, Y): C H subscript 2, C (start hexamer), double bond, C, C, double bond, C, C, double bond, C (end hexamer). The fourth C in the hexamer also has a single bond to an O H group.

Part 2. Special amino acid R groups.

Glycine (G l y, G): H.

Proline (P r o, P): The R group forms a pentameric ring with the amide group and alpha carbon of the amino acid backbone so the structure is N H (start pentamer), C H subscript 2, C H subscript 2, C H subscript 2, C H (end pentamer), C O O superscript minus.

Cysteine (C y s, C): C H subscript 2, S H.

Part 3. Hydrophilic amino acid R groups.

Polar hydrophilic:

Asparagine (A s n, N): C H subscript 2, C with a single bond, N H subscript 2, and a double bond O.

Glutamine (G l n, Q): C H subscript 2, C H subscript 2, C with a single bond, N H subscript 2, and a double bond O.

Serine (S e r, S): C H subscript 2, O H.

Threonine (T h r, T): C with single bonds to H, C H subscript 3, and O H.

Basic hydrophilic:

Lysine (L y s, K): C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, N H subscript 3 superscript plus.

Arginine (A r g, R): C H subscript 2, C H subscript 2, C H subscript 2, N H, C with a single bond, N H subscript 2 and a double bond, N H subscript 2 superscript plus.

Histidine (H i s, H): C H subscript 2, C (start pentamer), double bond, C, N H, C, double bond, N H superscript plus (end pentamer).

Acidic hydrophilic:

Aspartic acid (A s p, D): C H subscript 2, C O O superscript minus.

Glutamic acid (G l u, E): C H subscript 2, C H subscript 2, C O O superscript minus.

Return to Figure 4.3 Structures of the 20 amino acids commonly found in proteins

Extended description for: Figure 4.4 Formation of a peptide bond

Two unknown ionized amino acids release a water molecule during the formation of a peptide bond. The ionized carboxyl group on the first amino acid is attracted to the ionized

amino group on the second amino acid. The negatively charged oxygen from the carboxyl group and the two hydrogen ions from the amino group form the water molecule, resulting in peptide bond formation. The unbound amino group becomes the N terminus and the unbound carboxyl group is the C terminus.

Return to Figure 4.4 Formation of a peptide bond

Extended description for: Figure 4.5 Amino acids, peptides, and proteins

Amino acids are depicted as scattered blocks of varying colors. An arrow points from amino acids to the peptide, which is depicted by amino acid blocks connected on a wavy string. An arrow points from peptide to protein, which is depicted by

blocks on a longer string that folds and loops over itself.

Return to Figure 4.5 Amino acids, peptides, and proteins

Extended description for: Figure 4.6 Primary structure

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The protein is 25 amino acids long and begins at the N terminus, superscript plus H subscript 3 N, which is on the first amino acid G l y.

The remaining amino acids are P r o, T h r, G l y, (5) T h r, G l y, G l u, S e r, L y s, (10) C y s, P r o, L e u, M e t, V a l, L y s, V a l, L e u, A s p, A l a, (20) V a l, A r g, G l y, S e r, P r o, (25) A l a, which ends at C O O superscript minus (the carboxyl end).

Return to Figure 4.6 Primary structure

Extended description for: Figure 4.7 An alpha helix

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The ball-and-stick model shows an alpha helix where each carbonyl group in the backbone forms a hydrogen bond with an amide group.

The following items are identified in the legend: the alpha carbon (the central carbon of the peptide), carbonyl group (C double bond O), amide group (N single bond H), R group (side chain), H atom, single bond, peptide bond, and hydrogen bond.

The helix is formed by eleven amino acids where five are required to complete a full turn of the helix. The hydrogen bonds that hold the helix structure occur between the oxygen of a carbonyl group and the hydrogen of the amide group that is directly below it. In this helix, there are hydrogen bonds between the carbonyl and amide groups of the

second and sixth, third and seventh, fourth and eighth, fifth and ninth, six and tenth amino acids, respectively.

Return to Figure 4.7 An alpha helix

Extended description for: Figure 4.8 A beta sheet

The ball-and-stick model shows a beta sheet where hydrogen bonds form between carbonyl groups in one polypeptide section and amide groups in a different part of the polypeptide.

The following items are identified in the legend: the alpha carbon (the central carbon of the peptide),

carbonyl group (C double bond O), amide group (N single bond H), R group (side chain), H atom, single bond, peptide bond, and hydrogen bond.

The beta sheet forms when adjacent strands run in the same direction, parallel, or in opposite directions, anti-parallel (this example). Each strand of the beta sheet has five amino acids. The top strand runs left-to-right while the bottom strand runs right-to-left. Similar to the alpha helix, there is a hydrogen bond from the oxygen of the carbonyl group of an amino acid above to the hydrogen of the amide group of an amino acid below. The adjacent hydrogen bond is

between the amide group on the top strand and the carbonyl group on the bottom strand. The directionality of the hydrogen bonds alternates but remains approximately parallel to each other while the alpha carbons extend away from the plane of the hydrogen bonds, alternating between forward or behind the plane of the page.

Return to Figure 4.8 A beta sheet

Extended description for: Figure 4.9 Tertiary structure

A. Ball and stick model. Very much like the skeleton of the protein where the balls represent the atoms and the sticks are the bonds. There is a lot of white space visible. Each atom type is represented by a different color.

B. Ribbon model. The primary structure of the peptide is visualized

by a string and the side chains (R groups, H ions) are not represented. The string becomes thicker and is in a different color when the amino acids are arranged in an alpha helix. The string becomes wide and flat to represent a beta sheet with an arrow at the end to represent the directionality.

C. Space-filling model. There is no color differentiation and the space that is taken up by the electron orbits blocks out all of the white space that was present in the ball-and-stick model.

Return to Figure 4.9 Tertiary structure

Extended description for: An illustration shows the three experimental setups (a, b, and c) to study protein structure and function

The active ribonuclease is subjected

to one of three treatments in each section and the treatment effect on the ribonuclease structure is depicted.

(a) The active ribonuclease is a counterclockwise, inward spiral that is held together by four disulfide (S - S) bonds. Each cysteine pair is depicted with a different color.

Treatment with urea plus 2-mercaptoethanol denatures the ribonuclease, making it inactive. The denatured ribonuclease has a single loop and each of the eight cysteines that were involved in the disulfide bonds has a hydrogen ion added (S - H).

(b) Treatment with urea alone, all 2-mercaptoethanol has been removed, results in a misfolded, and inactive, ribonuclease. There are four disulfide (S - S) bonds, but they are formed with incorrect partners, locking the protein into a non-functional conformation.

(c) Treatment after removing the urea along with most of the 2-mercaptoethanol results in an active properly folded ribonuclease. This protein has the appropriate spiral structure that is held together with disulfide bonds between the appropriate partner cystines.

Return to An illustration shows the

three experimental setups (a, b, and c) to study protein structure and function

Extended description for: Figure 4.10 Quaternary structure

(a) This enzyme consists of two identical polypeptide subunits, represented in light green and dark

green. Ribbons of light green on the left side and dark green on the right are mirror images. Beta sheets form an inward-facing cup, like the letter C, with a single alpha helix at the top of the C-like shape.

(b) Hemoglobin is made up of four subunits: two copies of the polypeptide depicted in magenta and two copies of the polypeptide depicted in blue. Each subunit is made of several alpha helices. The four polypeptides are arranged at the corners of a square with the subunits alternating so that copies are opposite each other.

Return to Figure 4.10 Quaternary

structure

Extended description for: Figure 4.11 Levels of protein structure

Morris, et al, *Biology For the AP® Course*, 1e, © 2022 BFW High School Publishers

The primary structure is the sequence of amino acids and is represented by

a ball-and-stick model of a peptide chain. The secondary structure results from interactions of nearby amino acids. The alpha helix is a ball-and-stick model of an amino acid sequence in a helical structure with dashed bonds. The beta sheet is two parallel chains of amino acids pointing in opposite directions and linked by vertical dashed lines. The tertiary structure is the three-dimensional shape of a polypeptide, which may have alpha helices, beta sheets, or both. The quaternary structure results from interactions of polypeptide subunits.

Return to Figure 4.11 Levels of protein structure

Extended description for: An illustration shows an amino acid and a ribbon model of a protein

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The amino acid backbone is superscript plus, H subscript 3, N, single bond, C, single bond, C O O superscript minus. The first C has a single bond up to a hydrogen atom and a single bond down to C H

subscript 2, single bond, O H.

The ribbon model of the protein is shaped like a closed clamshell where four beta sheets create the arch at the top and the bottom. There is a horizontal alpha helix at the top left and a vertical alpha helix at the front left.

Return to An illustration shows an amino acid and a ribbon model of a protein

Extended description for: Figure 5.1 DNA nucleotide structure

The structure is a deoxyribose sugar bound to both a phosphate group and a base. The phosphate group has a double bond to oxygen, single bonds to two negatively charged oxygen atoms, or ionized hydroxyl groups, and a single bond to an O which is bound to C 5 of the deoxyribose sugar,

a pentameric ring. The sequence is O, single bond, H subscript 2, C 5, C 4 H, C 3 (which is bound to an H and an O H), C 2 (bound to two hydrogen atoms), C 1 (Base and H), O (which also binds to C 4 to complete the pentameric ring). The base is bound to C 1 and is either A, G, T, or C.

Return to Figure 5.1 DNA nucleotide structure

Extended description for: Figure 5.2 Bases found in DNA

Morris, et al., *Biology for the AP* Course*, 1e, © 2022 BFW High School Publishers

The two purine bases are adenine (A) and guanine (G). The purine bases are composed of a hexamer that shares a

carbon-carbon double bond with a pentamer. Both carbons have single bonds to an N, which both have a single bond to the same carbon to complete the pentamer. There is one nitrogen-carbon double bond in the pentamer.

Adenine, A: Going counterclockwise from the first shared carbon: C, double bond, C, single bond, N, double bond, C, single bond, N, double bond, C, single bond, N H subscript 2. The last C is also the last atom in the hexameric ring.

Guanine, G: Going counter clockwise from the first shared carbon: C, double bond, C, single bond, N,

double bond, C (which also has a single bond, N H subscript 2), single bond, N H, single bond, C, double bond, O. The last C is also the last atom in the hexameric ring.

The two pyrimidine bases are thymine (T) and cytosine (C). The pyrimidine bases are composed of a single hexameric ring.

Thymine, T: Going clockwise from the bottom, N, single bond, C (with a double bond O), single bond, N, single bond, C, (with a double bond, O), single bond, C (with a single bond C H subscript 3), double bond, C.

Cytosine, C: Going clockwise from the bottom, N, single bond, C (with a

double bond O), single bond, N, double bond, C, (with a single bond, N H subscript 2), single bond, C, double bond, C.

Return to Figure 5.2 Bases found in DNA

Extended description for: Figure 5.3 Phosphodiester bonds

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows three deoxyribonucleotides connected by ionized phosphate groups. They overlay a wide blue arrow that points downward and is notched at the top.

Beginning at the top (first) phosphate group the structure is as follows where parentheses indicate substituent groups.

O superscript minus, single bond, P, parentheses, single bond left, O superscript minus, single bond right, double bond O, end parentheses, single bond, O, single bond, C 5 prime H subscript 2, single bond, C 4 prime H, single bond, O, single bond, C 1 prime H, parentheses, Base, end

parentheses, single bond, C 2 prime H subscript 2, single bond, C 3 prime H, single bond, O, single bond, P (the second phosphate group).

The pattern repeats for the second deoxyribose.

P (the third phosphate group), parentheses, single bond left, O superscript minus, single bond right, double bond O, end parentheses, single bond, O, single bond, C 5 prime H subscript 2, single bond, C 4 prime H, single bond, O, single bond, C 1 prime H, parentheses, Base, end parentheses, single bond, C 2 prime H subscript 2, single bond, C 3 prime H, single bond, O H.

The two phosphate groups that span from the 3 prime carbon of one deoxyribose to the 5 prime carbon of the next deoxyribose is termed the phosphodiester bond.

Return to Figure 5.3 Phosphodiester bonds

Extended description for: Figure 5.4 DNA directionality

The illustration depicts a D N A strand with four phosphate groups and deoxyribonucleotides, including the

structure of each base.

The beginning phosphate group, which is only bound to one deoxyribose via the C 5 prime, is known as the 5 prime phosphate group or the 5 prime end. The phosphate groups have bonds with the C 5 prime of the next deoxyribose sugar and to the C 3 prime of the previous deoxyribose (where applicable), this is called the phosphodiester bond. From the top to the bottom, the bases with a single bond from their nitrogen to the C 1 prime of the corresponding deoxyribose sugar are adenine, guanine, cytosine, and thymine. The chain ends with a

deoxyribonucleotide that has a 3 prime hydroxyl group (i. e., no phosphate group). This is also called the 3 prime end.

The fully depicted structure using S M I L E S notation is as follows.

O minus, P, parentheses, double bond, O, end parentheses, parentheses, O minus, end parentheses, O, 5 prime C, C 1, O, C H, parentheses, N 2 (pentamer), C, double bond, N, C 3 (hexamer), double bond, C 2 (end pentamer), N, double bond, C, N, double bond, C 3 (end hexamer), N H subscript 2, end parentheses, C, C 1 (also 3 prime), O, P, parentheses, double bond, O, end

parentheses, parentheses, O minus, end parentheses, O, 5 prime C, C 1, O, C H, parentheses, N 2, C, double bond, N, C 3, double bond, C 2, N, double bond, C, parentheses, N H subscript 2, end parentheses, N H, C 3, double bond O, end parentheses, C, C 1, O, P, parentheses, double bond, O, end parentheses, parentheses, O minus, end parentheses, O, 5 prime C, C 1, O, C H, parentheses, N 2, C, double bond, C, C, parentheses, N H subscript 2, end parentheses, double bond, N, C 2, double bond O, end parentheses, C, C 1, O, P, parentheses, double bond, O, end parentheses, parentheses, O minus, end parentheses, O, 5 prime C, C 1, O, C H, parentheses, N 2, C, double bond,

C, parentheses, C H subscript 3, end parentheses, C, parentheses, double bond O, end parentheses, N H, C 2, double bond O, end parentheses, C, C 1, O H.

Return to Figure 5.4 DNA directionality

Extended description for: Figure 5.5 DNA synthesis

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows a strand of three deoxyribonucleotides, from 5 prime to 3 prime. A fourth deoxyribonucleotide is ready to be

added to the 3 prime end of the D N A strand. The 5 prime carbon on this nucleotide has a chain of three phosphate groups instead of just one. An arrow from the 3 prime hydroxyl group of the D N A strand points to the bond between the first and second phosphate group indicating where the phosphodiester bond will form. A second arrow points from the three phosphate groups to the reaction product pyrophosphate (P P subscript i), which is two phosphate groups.

Return to Figure 5.5 DNA synthesis

Extended description for: Figure 5.6 DNA structure

(a) Space-filling model. The sugar-

phosphate backbone is two strings of sugar (purple spheres) with evenly distributed phosphates (yellow spheres). The bases are a series of parallel, linear clusters of white spheres that connect the two strings. The top ends of the strings are labeled as 3-prime (left) and 5-prime (right).

(b) Ribbon model. The sugar-phosphate backbone is represented by two blue ribbons that are connected by bars that represent the bases. Since there are four bases (T, A G, and C), the bars are in four different colors to demonstrate that T and A are always paired and that G and C are always paired. This model also shows that since A and G are

larger than C and T, they span greater than 60 percent of the distance between the two ribbons.

Return to Figure 5.6 DNA structure

Extended description for: Figure 5.7 Base pairing

Adenine (A) **Thymine (T)**

Morris, et al., *Biology for the AP* ® *Course*, 1e, © 2022 BFW High School Publishers

Guanine (G) **Cytosine (C)**

A and T are held together by two hydrogen bonds. Each bond is indicated by a dashed line.

Adenine (A) is composed of a pentameric ring that shares a carbon-carbon double bond with a hexameric ring. The pentameric N that does not have a double bond with carbon is bound to the deoxyribose. Moving around the hexamer counterclockwise from the first carbon in the shared bond: C, double bond, C, single bond, N, double bond, C, single bond, N, double bond, C, (single bond, N H subscript 2).

Thymine (T) is a hexameric ring. Moving around the hexamer

counterclockwise (with groups bound to the hexamer in parentheses). N, parentheses, single bond, deoxyribose, end parentheses, C, double bond, C, parentheses, C H subscript 3, end parentheses, C, parentheses, double bond O, end parentheses, single bond, N H, single bond, C, parentheses, double bond O, end parentheses.

One hydrogen bond occurs between the hydrogen of the adenine N H subscript 2 and a thymine double bond O group. The second hydrogen bond occurs with immediately adjacent atoms, the adenine N and the hydrogen of the thymine N H.

G and C are held together by three hydrogen bonds.

Guanine (G) is composed of a pentameric ring that shares a carbon-carbon double bond with a hexameric ring. The pentameric N that does not have a double bond with carbon is bound to the deoxyribose. Moving around the hexamer counterclockwise from the first carbon in the shared bond: C, double bond, C, single bond, N, double bond, C, parentheses, N H subscript 2, end parentheses, single bond, N H, single bond, C, parentheses, double bond O, end parentheses.

Cytosine (C) is a hexameric ring.

Moving around the hexamer counter-clockwise N, parentheses, deoxyribose, end parentheses, single bond, C, double bond, C, single bond, C, parentheses, N H subscript 2, end parentheses, double bond, N, single bond, C, parentheses, double bond O, end parentheses.

The first hydrogen bond is between the guanine double bond O and an H of the cytosine N H subscript 2. The second hydrogen bond is between the H of the guanine N H and the cytosine N. The third hydrogen bond is between the guanine N H subscript 2 and the cytosine double bond O.

Return to Figure 5.7 Base pairing

Extended description for: Figure 5.8 Ribose and deoxyribose

Both structures are pentameric rings of four carbon atoms and an oxygen atom. Each carbon is labeled with a prime number.

Ribose: O, single bond, C 1 prime, parentheses, single bond up, O H, single bond down, H, end parentheses, single bond, C 2 prime,

parentheses, single bond up, H, single bond down, O H (highlighted), end parentheses, single bond, C 3 prime, parentheses, single bond up, H, single bond down, O H, end parentheses, single bond, C 4 prime, parentheses, single bond down, H, single bond up, C 5 prime H subscript 2, single bond, O H, end parentheses.

Deoxyribose: This only differs from ribose at C 2 prime, whose single bond down is to an H instead of an O H.

Return to Figure 5.8 Ribose and deoxyribose

Extended description for: Figure 5.9 Uracil and thymine

Both bases are hexameric rings bound to a ribose. The structures are described as moving clockwise from the N that is bound to the sugar with any substituent placed in parentheses.

Uracil, U, is N, parentheses, single

bond, ribose, end parentheses, single bond, C, parentheses, double bond O, end parentheses, single bond, N H, single bond, C, parentheses, double bond O, end parentheses, single bond, C, parentheses, single bond H (highlighted), end parentheses, double bond C.

Thymine, T, is identical to uracil except that the N is bound to deoxyribose and the highlighted H in uracil is a highlighted methyl group C H subscript 3, in thymine.

Return to Figure 5.9 Uracil and thymine

Extended description for: An illustration shows the sugar-phosphate backbone with four nucleotide pairs and their hydrogen bonds

The left side begins with a phosphate which is bound to the C H subscript 2 group of deoxyribose. This first deoxyribose is bound to the base guanine, which has three hydrogen bonds with a hexameric, unnamed base. The base is bound to the

deoxyribose on the right side, which has an O H group pointing up, and the C H subscript 2 group is bound to the phosphate group below. This pattern is repeated three more times such that the last deoxyribose on the left has its O H group pointing down and the last deoxyribose on the right is bound to a phosphate group below it.

The four nucleotide pairs from top to bottom are Guanine - Unknown hexameric ring; Adenine - unknown hexameric ring with a C H subscript 3 group; Thymine - unknown hexamer and pentamer; and Cytosine - unknown hexamer and pentamer.

sugar-phosphate backbone with four nucleotide pairs and their hydrogen bonds

Extended description for: A bar graph plots the red chroma intensity of finch beaks versus their food and carotenoid treatment

The horizontal axis represents the food and carotenoid (Car) treatment for four groups of finches. The vertical axis represents the red

chroma intensity (saturation) between 0 and 1.0, in increments of 0.2.

The approximate saturation value and range of the corresponding error bar is as follows:

Group A: Food plus and Car plus, 0.94; 0.9 to 1.0;

Group B: Food plus and Car minus, 0.68; 0.57 to 0.79;

Group C: Food minus and Car plus, 0.76; 0.61 to 0.9;

Group D: Food minus and Car minus, 0.47; 0.36 to 0.58.

Return to A bar graph plots the red chroma intensity of finch beaks versus their food and carotenoid treatment

Extended description for: A line graph plots tumor volume each day after tumor injection

On the horizontal axis are the number of days after tumor injection ranging from 0 to 25 with breaks at 0, 7, 10, 15, 20, and 25. On the vertical axis is the tumor volume (millimeters cubed), which ranges from 0 to 2000 in

increments of 500. An arrow indicates that Met treatment began at about day 8 and extended until the last measurement. There are four groups: S T D, S T D plus Met, H F S, and H F S plus Met. All groups begin at 0 millimeters cubed at day zero, with imperceptible change until after day 10.

Beginning at day 13, the approximate tumor volume for each group is as follows:

S T D: day 13 - 150, day 16 - 300, day 19 - 500, day 22 - 600, and day 25 - 1100.

S T D plus Met: day 13 - less than 100, day 16 - 100, day 19 - 300, day 22 - 450, and day 25 - 700.

H F S: day 13 - 150, day 16 - 300, day 19 - 500, day 22 - 800, and day 25 - 1650.

H F S plus Met: day 13 - less than 100, day 16 - 100, day 19 - 400, day 22 - 500, and day 25 - 650.

Each data point is also accompanied by error bars. They cannot be separated by each group, but on average span 400 to 600 millimeters cubed.

A bracket encloses the end points for all four groups indicating that *p* equals 0.025.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Prokaryotic and eukaryotic cells both have a cell membrane, though prokaryotic cells are a small fraction

of the size of eukaryotic cells. The cross-section of the prokaryotic cell shows only the cytoplasm and some extracellular structures. Eukaryotic cells have a nucleus at the center, which is surrounded by the endoplasmic reticulum. Other distinct, cellular structures are also present.

Return to Figure 6.8 A prokaryotic and eukaryotic cell

Extended description for: Figure 6.9 A bacterial cell

Morris, et al., *Biology: For the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows an elongated bacterial cell with rounded ends. The parts of the bacterial cell described are as follows:

The gel-like substance enclosed within the cell is called the

cytoplasm.

The D N A of bacteria is typically one circular molecule, folded into many loops. The region of the cell containing the tightly coiled D N A is called the nucleoid.

Ribosomes are scattered throughout the cytoplasm and are depicted as small, yellow spheres.

Bacteria have both a cell membrane and a cell wall. These structures separate the cytoplasm from the outside of the cell. The cell membrane is located inside the cell wall.

A long, whip-like structure embedded

in the cell membrane and cell wall is called a flagellum, several are flagella.

Return to Figure 6.9 A bacterial cell

Extended description for: Figure 6.10 A bacterial pilus

Dr. Linda M. Stannard, University of Cape Town/Science Source
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In both images, the donor cell attaches to a recipient cell with a long, tube-like structure called the

pilus. The small circular pieces of D N A called plasmids passes through the pilus to the recipient cell, which did not have the plasmid before the transfer event.

Return to Figure 6.10 A bacterial pilus

Extended description for: Figure 6.11 Motile cilia

Top left to right: Andrew Syred/Science Source; SPL/Science Source; bottom left to right: Juergen Berger/Science Source; Eye of Science/Science Source

(a) Micrograph shows two teardrop-shaped *Chlamydomonas* cells that have two long and straight cilia. The cilia both extend from the same end of the cell and are twice as long as the cell.

(b) Micrograph shows an oblong-shaped *Paramecium* with short, fuzzy-looking cilia covering the cell surface.

(c) Micrograph shows sperm cells that have an oval-shaped head that tapers into a long, whip-like flagellum.

(d) Micrograph shows the epithelial cells that are columnar, with tens of cilia present on the airway side of the cells.

Return to Figure 6.11 Motile cilia

Extended description for: Figure 7.1 The endomembrane system

A double-layered nuclear envelope surrounds the cell nucleus, which has several pores. The endoplasmic

reticulum has many folds adjoining the nuclear envelope. The Golgi apparatus also has several folds. It releases small spheres called vesicles. The bilayer of the vesicles joins with the cell membrane bilayer to release vesicle contents outside of the cell. Lysosomes are small spheres that are scattered throughout the cytoplasm.

Return to Figure 7.1 The endomembrane system

Extended description for: Figure 7.5 The Golgi apparatus

Morris, et al., *Biology for the AP* Course*, 1e, © 2022 BFW High School Publishers
Photo: Biophoto Associates/Science Source

The illustration and the micrograph show that the Golgi apparatus is made of several envelope-like structures called cisternae, which are stacked tightly together. Some are receiving

vesicles from the E R, others are sending vesicles to the cell membrane and back to the E R.

Return to Figure 7.5 The Golgi apparatus

Extended description for: Figure 7.6 Lysosomes

Photo: Don W. Fawcett/Getty Images
Morris, et al., Biology for the AP® Course, 1e, © 2022 BFW High School Publishers

The illustration shows an enlarged view of vesicles and lysosomes. A vesicle from the Golgi apparatus containing enzymes merges with a molecule-containing vesicle from the E R to generate a lysosome. Inside the

lysosomes, the E R molecules fill binding sites of the Golgi-derived enzyme. The micrograph depicts lysosomes as opaque spheres.

Return to Figure 7.6 Lysosomes

Extended description for: Figure 7.9 Chloroplasts

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers
Dr. Jeremy Burgess/Science Source

The chloroplast is shaped like a bean and has an outer membrane that completely surrounds an inner membrane. The chloroplast contains layers of disc-like structures called thylakoids. In the micrograph, the thylakoids are dense, opaque structures connected by thin black

lines.

Return to Figure 7.9 Chloroplasts

Extended description for: Figure 7.10 Cytoskeleton

An illustration shows a row of nucleated epithelial cells, which appear to have microvilli. Microfilaments are highlighted in one cell while microtubules are highlighted in another.

(a) Microfilament. In the cell, microfilaments appear as short strings that can join ends and overlap. They line the entire interior of the cell membrane, even the microvilli. An individual microfilament is depicted as two chains of spheres that are intertwined together.

(b) Microtubule. In the cell, a small object sits next to the nucleus and several lines depicting microtubules radiate outwards from it. The microtubule appears to be a larger structure than the microfilament. Two different spheres are arranged in strings that alternate in a long, thin sheet of the spheres. This sheet is twisted to form a hollow tube that is

the microtubule.

Return to Figure 7.10 Cytoskeleton

Extended description for: Visual Synthesis 2.1 A Typical Animal Cell and a Typical Plant Cell

Morris, et al., Biology for the AP* Course, 1e, © 2012 BFW High School Publishers

The animal cell has a spherical nucleus at the center with a diameter of about two micrometers. The nucleus is the storehouse for the cell's genetic information and the site for R N A synthesis, it is surrounded by

layers of the endoplasmic reticulum. The endoplasmic reticulum is involved in both protein and lipid synthesis.

The Golgi apparatus is next to the E R and has a multilayered structure. It modifies and sorts proteins and lipids as they move to their final destinations into or out of the cell. Several of the lysosomes and vesicles that carry these products are present in the cytoplasm. Lysosomes contain enzymes that break down macromolecules such as proteins, nucleic acids, lipids, and carbohydrates.

Mitochondria produce most of the A

T P that serves as the energy currency of the cell. There are several of them inside of an animal cell.

Along the inner periphery of the plasma membrane is the cytoskeleton. The cytoskeleton is a network of protein filaments and other associated proteins that provide the cell with an internal structural framework. The cell membrane is composed of phospholipids and proteins and regulates the passage of materials into and out of the cell. Microtubules are depicted to one side of the nucleus.

All of the cellular components of the plant cell are enclosed within the cell

membrane, which is present on the inner periphery of the cell wall. The plant cell wall is a rigid barrier composed of polysaccharides.

At the center of the cell is a large vacuole that is surrounded by the cytoplasm and other cellular components. Vacuoles give plants structural rigidity by absorbing water and contributing to turgor pressure.

The nucleus is on one side of the cell, between the cell membrane and the vacuole. The endoplasmic reticulum surrounds part of the nucleus and portions of the E R appear to extend into the cytoplasm of nearby cells. The Golgi apparatus, vesicles, and

mitochondria are also present.

There are also multiple chloroplasts, which are about two micrometers wide and three micrometers long. Chloroplasts enable plant cells to harness the energy of sunlight to synthesize sugars.

The cytoskeleton is present throughout the cytoplasm but appears to have less structure or organization than in animal cells.

Return to Visual Synthesis 2.1 A Typical Animal Cell and a Typical Plant Cell

Extended description for: Figure 8.1 Surface area and volume

OBJECT	SURFACE AREA	VOLUME	VARIABLES
Cube	$SA = 6s^2$	$V = s^3$	s = side length
Rectangular solid 	$SA = 2lh + 2lw + 2wh$	$V = lwh$	l = length w = width h = height
Sphere	$SA = 4\pi r^2$	$V = \frac{4}{3}\pi r^3$	r = radius
Cylinder	$SA = 2\pi r^2 + 2\pi rh$	$V = \pi r^2 h$	r = radius h = height

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The column headers are: Object; Surface area; Volume; and Variables. (All variable letters are written in italics.)

The column headers are: Object,

Surface area, Volume, and Variables. The row entries are as follows:

Row 1. Object: A cube with a side labeled s; Surface Area equals 6 times s square; Volume equals s cube; and Variables: s equals side length.

Row 2. Object: A rectangle with a short vertical side labeled h, a long horizontal side labeled l, and a short horizontal side labeled w; Surface Area equals 2 l h plus 2 l w plus 2 w h; Volume equals l w h; and Variables: l equals length, w equals width, and h equals height.

Row 3. Object: A sphere with distance from the center to the outer edge is r; Surface Area equals 4 pi r square;

Volume equals three fourths pi r cube; and Variables: r equals radius.

Row 4. Object: A cylinder with its vertical side labeled h and the distance from the center of the cylinder to the outer edge is r; Surface Area equals 2 pi r square plus 2 pi r h. Volume equals pi r square h; and Variables: r equals radius and h equals height.

Return to Figure 8.1 Surface area and volume

Extended description for: Figure 8.3 Intestinal villi and microvilli

The illustration shows a cross-section of the small intestines. There are four layers to the small intestine. The outermost layer is thin, with blue and red dots. Next is a layer of rounded cells, then a layer of long flat, and overlapping cells. Next is the internal

lining of finger-like villi which appears to have small blood vessels running throughout and underneath. A magnified illustration and a micrograph show that the villi cells are connected by tight junctions and project thread-like microvilli.

Return to Figure 8.3 Intestinal villi and microvilli

Extended description for: Figure 8.7 Bulk flow

(a) An illustration of a human figure with an overlay of the veins and arteries inside the body, which branch out from the heart and extend to the toes, fingers, and head.

(b) A tree with arrows depicting the transportation of nutrients. Two point up from the roots, along the trunk and branches, to end at the leaves. A second set of arrows points down from the leaves and back toward the roots.

Return to Figure 8.7 Bulk flow

Extended description for: Figure 9.2 Phospholipid structure

The illustration shows three phospholipid models according to

their hydrophilic (head) and hydrophobic (tail) groups.

1. The polar head group is depicted as a yellow sphere with two leg-like sticks (the hydrophobic tails). The left leg is straight while the right has a kink that points the second half at an angle to the right.

2. The chemical structure. The polar head group consists of a choline group, phosphate group, and a glycerol backbone that binds the two fatty acid chains. The left is a straight eighteen-carbon chain whereas the right tail is an eighteen-carbon chain with a kink due to a double bond at C 8. Choline structure: C H subscript 3,

N superscript plus with single bonds to two C H subscript 3, C H subscript 2, C H subscript 2 [this C binds to the first O of the phosphate group].

3. A space-fill model. The choline group is primarily carbon and hydrogen spheres atop the yellow phosphorous atom, which is dotted with red oxygen atoms. The structure forks at the glycerol backbone, which also has several oxygen atoms. The fatty acid chains are thick, rope-like structures of carbon and hydrogen atoms.

Return to Figure 9.2 Phospholipid structure

Extended description for: Figure 9.3 Different phospholipid structures

(a) Micelle: A cross-section shows a spherical structure made of phospholipids. The spherical hydrophilic head points toward the outside of the micelle structure, while a single hydrophobic tail points toward the center.

(b) Bilayer: A lateral sectional view

shows two layers of phospholipids. Each layer has the polar head group (hydrophilic) oriented outward and the nonpolar tails (hydrophobic), oriented inwards.

(c) Liposome: A cross-section shows a phospholipid bilayer but on a smaller scale than a cell. This creates a small hydrophilic cavity in the middle of the sphere.

Return to Figure 9.3 Different phospholipid structures

Extended description for: Figure 9.5 Saturated and unsaturated fatty acid tails

(a) Saturated fatty acid chains lack double bonds, resulting in phospholipids with a straight structure that favors tight packing. The chemical formula of stearic acid is: C H subscript 3, parentheses, C H subscript 2, end parentheses,

subscript 16, C O O H. The structure of stearic acid is: C O O H, C H subscript 2, repeated 16 times, C H subscript 3. An illustration shows several phospholipids lined up neatly.

(b) Unsaturated fatty acids have one or more double bonds that introduce kinks in the phospholipids, reducing the tightness of packing. An illustration shows a sequence of phospholipid lipid heads with kinked tails. The formula of oleic acid is: C H subscript 3, parentheses, C H subscript 2, end parentheses, subscript 7, C H double bond C H, parentheses, C H subscript 2, end parentheses, subscript 7, C O O H. The structure of oleic acid is: C O O H,

C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H, double bond, C H, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 2, C H subscript 3.

Return to Figure 9.5 Saturated and unsaturated fatty acid tails

Extended description for: Figure 9.6 Cholesterol

Cholesterol has a hydroxyl group that comprises the hydrophilic head group, which is bound to the hydrophobic rigid ring structure, three hexameric rings and one pentameric ring. The shared bond

between the first two hexameric rings and the shared bond between the third hexameric ring and the pentameric ring both have a methyl group. The second hexameric ring has a double bond. An eight-carbon hydrophobic hydrocarbon tail is attached to the pentameric ring at the bottom.

Return to Figure 9.6 Cholesterol

Extended description for: Figure 9.7 Cholesterol in the lipid bilayer

The amphipathic structure of cholesterol allows it to pack tightly with phospholipids. Cholesterol molecules are depicted as a short, straight vertical line that then angles to the left. It is topped by a small blue

sphere. An enlarged view of two lipid molecules shows a cholesterol molecule attached to the polar head group of one of the lipid molecules by the hydrophilic spherical head group. The vertical hydrophobic tail of the cholesterol molecule is attached to the fatty acid tail of the second lipid molecule.

Return to Figure 9.7 Cholesterol in the lipid bilayer

Extended description for: Figure 9.8 Membrane proteins

The illustration shows three types of embedded proteins in a phospholipid bilayer. Each protein completely spans the bilayer with one side exposed to the cytoplasm and the other to the extracellular fluid.

1. Transport protein. A cylindrical protein with a hollow center through

which it can transport molecules or proteins.

2. Receptor protein. A molecule binds a pocket on the extracellular exposed side of the protein, creating a stimulus or other signal on the cytoplasmic side of the membrane.

3. Anchor proteins. Two proteins are side-by-side. Each protein has a hydrophilic bulb on the extracellular side and two on the cytoplasmic side. The cytoplasmic bulbs bind microfilaments.

Return to Figure 9.8 Membrane proteins

Extended description for: Figure 9.9 Integral and peripheral membrane proteins

The lipid bilayer separates the cytoplasm from the extracellular fluid. The proteins are depicted with ribbon models.

1. Integral membrane proteins include transmembrane proteins that span the entire membrane. These

proteins have alpha-helical secondary structures, which span the hydrophobic portion of the bilayer. There are three examples of proteins with one, three, or many transmembrane domains.

2. Peripheral membrane proteins are temporarily associated with either the internal or the external side of the membrane. Integral membrane proteins bind to peripheral proteins (small polypeptide chains) on either side of the lipid bilayer.

Return to Figure 9.9 Integral and peripheral membrane proteins

Extended description for: A schematic shows the four steps in fluorescent recovery after photobleaching, F R A P, which helps determine the mobility of proteins in a cell

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Step 1: The membrane is labeled with fluorescent molecules, resulting in a uniform fluorescence over the entire membrane. A small area is outlined on a fluorescent microscopy image of a fluorescent cell.

Step 2: A laser beam is used to bleach a small portion of the area with fluorescent molecules.

Step 3: Photobleaching causes a bleached area where there is no fluorescence. Fluorescent microscopy images show that the bleached portion of a fluorescent cell is no longer visible.

Step 4: Fluorescence gradually returns to the bleached area because

of the movement of fluorescent proteins into the area. The bleached area is visible again with fluorescent microscopy.

A graph compares fluorescence levels in the cell membrane during F R A P. The fluorescence (in the bleached area) is high before bleaching, which almost completely eliminates fluorescence. Fluorescence rises gradually during the recovery phase but does not reach the higher, pre-bleaching levels.

Return to A schematic shows the four steps in fluorescent recovery after photobleaching, F R A P, which helps determine the mobility of proteins in

a cell

Extended description for: An illustration shows two phospholipid bilayer models

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The sandwich model has a uniform layer of protein on both sides of the cell membrane.

The fluid mosaic model has a lipid bilayer with some proteins that span

the bilayer and other proteins that have a small part embedded in the bilayer.

Return to An illustration shows two phospholipid bilayer models

Extended description for: Figure 10.1 Diffusion

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A beaker is separated in half with a permeable membrane. The left side of the membrane has a higher solute concentration than the solute on the right. Four arrows point to the right and one to the left, indicating greater movement of solute from the left to

the right than in the other direction. There is net movement of solute from the area of higher solute concentration to the area of lower solute concentration.

A second beaker shows that over time, there is an equal concentration of solute on each side. One arrow points to the right side of the membrane and one to the left, indicating equal movement of solutes across the membrane. There is no net movement of solute but movement in both directions continues.

Return to Figure 10.1 Diffusion

Extended description for: Figure 10.2 Simple diffusion and facilitated diffusion

The illustration shows a lipid bilayer separating the extracellular fluid from the cell cytoplasm. Three types of molecules are in the extracellular

fluid and an arrow indicates that the concentration gradient is higher in the extracellular fluid than in the cytoplasm.

1. Simple diffusion. The smallest molecule from the extracellular region moves directly through the cell membrane into the cytoplasm.

2. Facilitated diffusion.

(a) Channel protein. A small molecule passes through the narrow channel of a protein transporter that is open on both sides of the cell membrane.

(b) Carrier protein. A protein has a binding pocket opened toward the extracellular fluid. When the third

and largest molecule enters, the extracellular side closes, opening the cytoplasmic side for the molecule to exit the protein into the cytoplasm.

Return to Figure 10.2 Simple diffusion and facilitated diffusion

Extended description for: Figure 10.3 Primary active transport

The illustration shows a lipid bilayer separating extracellular fluid from the cytoplasm. An arrow indicates that the concentration gradient is higher on the cytoplasmic side than in the extracellular fluid. Carrier proteins

transport molecules from the extracellular fluid where there are only a few, to the cytoplasm where there are many.

A molecule is bound to the carrier protein in the extracellular fluid and an arrow from the A T P molecule motions clockwise just beneath the protein carrier on the cytoplasmic side. This indicates that a molecule of A T P is used to obtain the conformation of the protein that opens the binding pocket to the cytoplasm.

Return to Figure 10.3 Primary active transport

Extended description for: Figure 10.4 The sodium–potassium pump

The illustration shows a lipid bilayer separating the extracellular fluid from the cytoplasm. An arrow indicates that the sodium ion (N a plus) concentration gradient is higher in the extracellular fluid than in the cytoplasm. Another arrow indicates that the potassium ion (K plus)

concentration is higher in the cytoplasm than the extracellular fluid. Four carrier proteins are embedded in the bilayer to depict the four steps of the sodium-potassium pump.

1. The carrier protein is open to the cytoplasm. Three N a plus binding sites are filled with N a plus from the cytoplasm. A molecule of A T P is used.

2. The carrier protein is open to the extracellular fluid where the N a plus atoms are released.

3. The carrier protein is still open to the extracellular fluid and two K plus binding sites are filled with K plus atoms.

4. The carrier protein is open to the cytoplasm where the K plus atoms are released.

N a plus movement is from the cytoplasm out into the extracellular fluid while the movement of K plus is from the extracellular fluid into the cytoplasm.

Return to Figure 10.4 The sodium–potassium pump

Extended description for: Figure 10.5 Secondary active transport

1. Protons are pumped across the membrane by primary active transport. A carrier protein is open toward the extracellular fluid, where it is releasing two protons after consuming a molecule of A T P.

Protons and another molecule are present in both the cytoplasm and the extracellular fluid, but there are more of the other molecule outside of the cell than inside.

2. The proton pump generates an electrochemical gradient, with a higher concentration of protons outside the cell and a lower concentration of protons inside the cell. Arrows pointing inward indicate that the proton concentration gradient and electrical gradient are both lower in the cytoplasm. The cytoplasmic side of the cell membrane is negatively charged and there are only a few protons remaining inside the cell. The

extracellular fluid side of the membrane has a positive charge and a lot of both protons and the other molecule.

3. A transport protein uses the proton electrochemical gradient to move a different molecule out of the cell against its concentration gradient. A different type of carrier protein is open toward the cytoplasmic side. Two protons are released into the cytoplasm the other molecule is expelled into the extracellular fluid.

Return to Figure 10.5 Secondary active transport

Extended description for: Figure 10.6 Exocytosis and endocytosis

Exocytosis. A vesicle containing cell-derived molecules moves toward the cell surface where its lipid bilayer merges with the cell membrane. This releases the molecules into the extracellular fluid.

Endocytosis. A vesicle forms at the cell membrane, trapping molecules

from the extracellular fluid. The vesicle moves into the cytoplasm.

Return to Figure 10.6 Exocytosis and endocytosis

Extended description for: Figure 10.7 Phagocytosis

Valentina Mercanti et al. 2006. "Selective Membrane Exclusion in Phagocytic and Macropinocytic cups." *Journal of Cell Science* 119:4079–4087. doi:10.1242/jcs.03190

The spherical yeast cell is bright red and the cell membrane is green.

1. The amorphous amoeba encounters the yeast cell and begins to extend the cell membrane around the edges of the yeast cell.

2. The cell membrane has almost completely encapsulated the red yeast

cell; a small red bleb still remains outside the amoeba.

3. The yeast cell is inside the amoeba and surrounded by a green circle, which indicates that the yeast-containing vesicle originated at the cell membrane.

Return to Figure 10.7 Phagocytosis

Extended description for: An illustration shows two beakers divided in half with permeable membranes

Time 1. A beaker is separated in half with a permeable membrane. The left side of the membrane has a higher solute concentration than the solute on the right. Four arrows point to the

right and one to the left.

Time 2. The second beaker has an equal concentration of solute on each side of the membrane. One arrow points to the right side of the membrane and one to the left.

Return to An illustration shows two beakers divided in half with permeable membranes

Extended description for: Figure 11.2 Osmosis

Both sides of the container are filled with water, but the water on side B contains solutes. The water movement from side B to side A is minimal compared to the water movement from side A to side B.

Return to Figure 11.2 Osmosis

Extended description for: Figure 11.3 A molecular view of osmosis

Both sides of the container are filled with water, represented by space filling models, but the water on side B contains solutes. The water molecules bounce off of the solute molecules. The water movement from side B to

side A is minimal compared to the water movement from side A to side B.

Return to Figure 11.3 A molecular view of osmosis

Extended description for: Figure 11.4 Osmotic and hydrostatic pressure

At the bottom of each U-bend is a selectively permeable membrane. In the first image, water fills the tube to the left of the membrane, while solute lies to the right of the membrane. The selectively permeable membrane allows movement of water but not solutes, so a thick arrow denotes the

movement of water from left to right, whereas the movement of water from right to left is represented by a thin arrow.

In the second image, the liquid level has fallen on the left of the membrane and risen on the right, as water moves by osmosis from a region of lower to higher solute concentration. The arrow representing water movement from left to right is now slightly thinner.

In the final image, the left has fallen further and the right has risen higher. The difference between the levels is the osmotic pressure. Net movement of water stops (denoted by equal

thickness arrows across the membrane) when osmotic pressure equals hydrostatic pressure due to gravity.

Return to Figure 11.4 Osmotic and hydrostatic pressure

Extended description for: Figure 11.5 Osmotic pressure and an external force

Both sides of the container are filled with water, but the water on side B contains solutes and force is applied from above. The net water movement

from side B to side A due to pressure is equal to net water movement from side A to B due to osmosis.

Return to Figure 11.5 Osmotic pressure and an external force

Extended description for: Figure 11.6 Changes in red blood cell shape due to osmosis

Hypertonic: The red blood cell shrinks. An arrow indicates that water molecules move out of the cell.

Isotonic: The red blood cell remains normal. A double headed arrow

indicates equal movement of water molecules in and out of the cell.

Hypertonic: The red blood cell swells and ruptures. An arrow indicates movement of water molecules into the cell.

Return to Figure 11.6 Changes in red blood cell shape due to osmosis

Extended description for: Figure 11.7 Contractile vacuole

a.

Michael Abbey/Science Source

b.

Micrograph (a) shows an oval-shaped paramecium with a full contractile vacuole. The vacuole appears as a crater inside the paramecium. Micrograph (b) shows the paramecium after emptying its contractile vacuole. The vacuole now appears just as a circle inside the paramecium.

Return to Figure 11.7 Contractile vacuole

Extended description for: Figure 11.8 Turgor pressure

The shape of the plant cells, from higher extracellular solute concentration to lower, are as follows,

Hypertonic: The plant cell shrinks with its inner components compressed. An arrow indicates that water molecules move out of the cell. A corresponding illustration shows a wilted or flaccid plant.

Isotonic: The plant cell remains normal. Two arrows indicate equal movement of water molecules in and out of the cell.

Hypertonic: The plant cell swells. An arrow indicates movement of water molecules into the cell. A corresponding illustration shows an upright, perky or turgid plant.

Return to Figure 11.8 Turgor pressure

Extended description for: Figure 11.9 Water movement up a tree

The sun shines brightly on the tree. Arrows point to the roots, travel up

the trunk of the tree, through the leaves, and exit the foliage as wavy outward arrows. Root p s i equals negative 0.10 bar, stem p s i equals negative 1.00 bar, and leaf p s i equals negative 2.00 bar.

Return to Figure 11.9 Water movement up a tree

Extended description for: An illustration shows water drawn by a branch from a reservoir and water drawn by a vacuum pump from a reservoir

Water flows through pipes to each reservoir, the flow rate of which is represented in a bar graph. In the graph, the plant and vacuum pump are on the horizontal axis and flow rate is along the vertical axis. The flow rate corresponding to the plant is double the vacuum pump.

Return to An illustration shows water drawn by a branch from a reservoir and water drawn by a vacuum pump from a reservoir

Extended description for: Figure 12.6 Two hypotheses for the origin of the eukaryotic cell

Morris, et al., Biology for the AP* Course, 1e, © 2022 BFW High School Publishers

Hypothesis 1: Eukaryotic cells evolved from an ancestral archaeon and only later incorporated the proteobacterial cell that became a mitochondrion.

The ancestral archaeon contains D N A, cytoplasm, and a cell membrane that undergo scission. During scission, the membrane gets infolded and divides into three hemispherical regions which then again form a circular arrangement. True eukaryotic cells with nucleus and cytoplasm contain a cytoskeleton and endomembrane system. Then aerobic probacterium gets engulfed and mitochondria gets injected into the ancestral archaeon forming a heterotropic eukaryote.

Hypothesis 2: Eukaryotic cells evolved from a symbiosis between an archaeon and a proteobacterium. The proteobacterium became a mitochondrion.

The probacterium gets directly injected into the archaeon to form mitochondria in the cell which acts as a symbiont. Then the cell membrane gets infolded to form true eukaryote and two mitochondria are produced forming a heterotropic eukaryote.

Return to Figure 12.6 Two hypotheses for the origin of the eukaryotic cell

Extended description for: Figure 13.1 Kinetic and potential energy

All three parts of the illustration shows three steps of a staircase with the position of the ball varying in each part. First part: High potential energy. The ball remains stationary at the top of the staircase. Second part: Kinetic energy. The ball bounces down to the bottom-most step of the

staircase. Third part: Low potential energy. The ball remains stationary at the bottom of the staircase.

Return to Figure 13.1 Kinetic and potential energy

Extended description for: Figure 13.4 ATP and its chemical relatives

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A T P, A D P, and A M P, each is composed of three subunits: adenine,

ribose, and phosphate groups.

The structure of adenine shows a benzene, clockwise, fused with a pentane, anticlockwise, at their fourth and tenth positions, respectively. The first and third carbon atoms of the benzene are replaced with nitrogen; the sixth carbon with azanide, N H subscript 2; the seventh carbon with nitrogen; and the ninth carbon with nitrogen bonded to hydrogen of a ribose unit.

The structure of the ribose unit shows a cyclopentene in which the first carbon is bonded to adenine; the second and third carbon atoms are bonded to hydrogen, toward the

carbon axis, and a hydroxyl group, O H; the fourth carbon is bonded to C H subscript 2; which is further bonded to the phosphate group and hydrogen, away from the carbon axis; and the fifth carbon is replaced with oxygen.

(A) A T P shows three phosphate groups attached to the C H subscript 2 of ribose. The phosphate group shows a phosphorous single bonded to two negatively charged oxygen atoms and a neutral oxygen atom, and double bonded to an oxygen atom. The neutral oxygen atom is single bonded to second phosphorous which is single bonded to one negatively charged oxygen atoms and a neutral oxygen atom and double bonded to an

oxygen atom. The neutral oxygen atom of second phosphorus is further single bonded to third phosphorous. The third phosphorous is finally single bonded to two negatively charged oxygen atoms and double bonded to an oxygen atom.

A text reads, The bonds linking these phosphate groups have high potential energy.

(B) A D P shows two phosphate groups attached to the C H subscript 2 of ribose. The phosphate group shows a phosphorous single bonded to two negatively charged oxygen atoms and a neutral oxygen atom, and double bonded to an oxygen atom. The

neutral oxygen atom is single bonded to a second phosphorous which is single bonded to two negatively charged oxygen atoms and double bonded to an oxygen atom.

A text reads, A D P has two phosphate groups and less chemical energy than A T P.

(C) A M P shows one phosphate group attached to the C H subscript 2 of ribose. The phosphate group shows a phosphorous single bonded to two oxygen atoms and a negatively charged oxygen atom, and a double bonded oxygen atom.

A text reads, A M P has one phosphate group and less chemical energy than

A T P and A D P.

Extended description for: Figure 13.5 The first law of thermodynamics

A single unit of energy is represented by a cube. Total energy before consists of four units arranged as a two by two matrix. Total energy after consists of four units arranged linearly.

Return to Figure 13.5 The first law of thermodynamics

Extended description for: Figure 13.6 The second law of thermodynamics

A single unit of energy is represented by a cube. Total energy before consists of four units arranged as a single form in a two-by-two matrix. During transformation, the energy is split into two. One-fourth of the energy is depicted as a single unit.

Text reads: Energy, often in the form of heat, resulting in increased entropy. Three fourths of the energy is depicted as three units arranged linearly. Text reads: Energy available to do work.

Return to Figure 13.6 The second law of thermodynamics

Extended description for: Figure 13.7 A chemical reaction

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The carbon dioxide molecule is represented by C O subscript 2 and consists of a central carbon atom double bonded to two oxygen atoms, one on either side.

The water molecule is represented by

H subscript 2 O and consists of a central oxygen atom single bonded to two hydrogen atoms, one on either side.

During the reaction, one C O double bond of C O subscript 2 and one H O single bond of H subscript 2 O are disrupted. A double headed arrow connects carbon of C O subscript 2 with oxygen of H subscript 2 O. Another double headed arrow connects oxygen of C O subscript 2 with hydrogen of H subscript 2 O. Text above the reactant reads: Old bonds break between carbon and oxygen in C O subscript 2, and hydrogen and oxygen in H subscript 2 O.

The carbonic acid molecule, yielded as the product, is represented by H subscript 2 C O subscript 3. It consists of a central carbon double bonded to an oxygen atom and single bonded to two hydroxyl, O H, groups. The C O single bond and O H single bond are labeled new covalent bonds. Text above the product reads: New bonds form between the carbon of C O subscript 2 and oxygen of H subscript 2 O, and between one oxygen of C O subscript 2 and one hydrogen of H subscript 2 O.

Return to Figure 13.7 A chemical reaction

Extended description for: Figure 13.8 Endergonic and exergonic reactions

In both graphs free energy (G) is plotted along the vertical axis and course of reaction along the horizontal axis. Graph (a) illustrates an endergonic or non-spontaneous reaction. A curve starts from low free energy and remains constant for a

while, representing reactants. It then increases exponentially up to a point and remains constant, representing products. The difference in the free energy level of reactants and products is marked, Amount of energy required, positive delta G.

Graph (b) illustrates an exergonic or spontaneous reaction. A curve starts from high free energy and remains constant for a while, representing reactants. It then decreases steeply to a point and remains constant, representing products. The difference in the free energy level of reactants and products is marked, Amount of energy released, negative delta G.

Return to Figure 13.8 Endergonic and exergonic reactions

Extended description for: Figure 13.9 ATP hydrolysis

During the reaction, Adenosine triphosphate, A T P, combines with a molecule of water, H subscript 2 O, to yield Adenosine diphosphate, A D P, and inorganic phosphate, P i.

The structure of A T P has adenine, ribose, and phosphate groups. Adenine has a benzene, clockwise, fused with a pentane, anticlockwise, at their fourth and tenth positions,

respectively. The first and third carbon atoms of the benzene are replaced with nitrogen and the sixth carbon with azanide, H subscript 2 N, while the seventh carbon is replaced with nitrogen and the ninth carbon with nitrogen bonded to hydrogen of a ribose unit.

Ribose has a cyclopentene in which the first carbon is bonded to adenine, the second and third carbon atoms are bonded to hydrogen, toward the carbon axis, and a hydroxyl group, O H, the fourth carbon is bonded to C H subscript 2 bonded to three phosphate groups, P O subscript 4, and hydrogen, away from the carbon axis, and the fifth carbon is replaced

with oxygen.

The phosphate group contains a phosphorous single bonded to two negatively charged oxygen atoms and a neutral oxygen atom and double bonded to an oxygen atom.

A T P loses the third phosphate group and is replaced with the hydroxyl, O H, group from water to become A D P. The released phosphate combines with the hydrogen atom from water to yield inorganic phosphate. Free energy is released during the process.

Return to Figure 13.9 ATP hydrolysis

Extended description for: Figure 13.10 Energetic coupling

The exergonic reaction reads: A T P combines with H subscript 2 O to yield A D P and P subscript i. Delta G subscript 1 is negative 7.3 kilocalories per mole.

The endergonic reaction reads: Glucose combines with P subscript i to yield glucose-6-phosphate and H subscript 2 O. Delta G subscript 2 is

positive 3.3 kilocalories per mole.

The coupled reaction reads: Glucose combines with A T P to yield glucose-6-phosphate and A D P. Delta G is negative 4 kilocalories per mole.

Return to Figure 13.10 Energetic coupling

Extended description for: Figure 13.11 Catabolism and anabolism

Macromolecules (carbohydrates, proteins, fats, and nucleic acids) are converted into their individual subunits (sugars, amino acids, fatty acids, and nucleotides) through catabolism. During the process, A D P

combines with a nucleotide molecule and yields an A T P and a water molecule.

Subunits are converted into macromolecules through anabolism. During the process, A T P combines with a water molecule to release an A D P and a nucleotide molecule.

Return to Figure 13.11 Catabolism and anabolism

Extended description for: Figure 14.1 Enzymes

Carbohydrates break down into monosaccharides. Carbohydrates show several joined hexagons while monosaccharides show individual hexagons. Proteins break down into amino acids. Proteins show a chain of

squares while amino acids show individual squares. Lipids break down into glycerol and fatty acids. Lipids show a row of circles with each attached to a straight and a kinked tail while amino acids show circular glycerol separated from a straight and a kinked tail of fatty acid.

Return to Figure 14.1 Enzymes

Extended description for: Figure 14.2 Transition state

In the graph, free energy (G) is plotted along the vertical axis and course of reaction along the

horizontal axis. A curve starts from optimal free energy and remain constant for a while, representing reactants. The curve then increase to its peak level, where reactants attain the transition state. Finally, the curve slope downward and remain constant for a while, representing products.

The difference in free energy level of reactants and transition state is marked, E subscript A. Text reads: All reactions require an input of energy, called activation energy, E subscript A, to proceed.

The difference in free energy level of reactants and products is marked, delta G.

Return to Figure 14.2 Transition state

Extended description for: Figure 14.3 Enzyme function

In the graph, free energy is plotted along the vertical axis and course of reaction along the horizontal axis. Two curves mark the energy levels for uncatalyzed and catalyzed reactions. They start from optimal free energy and remain constant for a while,

representing reactants. The curves then increase to their peaks, where reactants attain the transition state. Finally, they slope downward and remain constant for a while, representing products.

The difference in free energy level of reactants and transition state is marked, E subscript A. The E subscript A of catalyzed reaction is lower than that of uncatalyzed reaction. Text corresponding to the peaks reads: An enzyme accelerates the reaction by reducing E subscript A.

The difference in free energy levels of reactants and products is marked,

delta G. Text reads: Delta G is the same with and without an enzyme.

Return to Figure 14.3 Enzyme function

Extended description for: Figure 14.4 Steps of an enzyme-catalyzed reaction

(a) Catabolic reaction: Two attached substrates bind into the pockets of enzyme (E plus S) forming an enzyme-substrate complex (E S). This

leads to enzyme-substrate complex (E P) where bonds between both substrates break. Finally, the two separated products detach from the enzyme (E plus P).

(b) Anabolic reaction: Two separate substrates bind into the connected pockets of enzyme (E plus S) forming an enzyme-substrate complex (E S). This leads to enzyme-substrate complex (E P) where both substrates attach together. Finally, an attached product detach from the enzyme (E plus P).

Return to Figure 14.4 Steps of an enzyme-catalyzed reaction

Extended description for: An illustration shows the movement of substrate in a beaker from one section to the other over a period of time

The beaker is divided into two sections, 1 and 2 by a membrane. During the initial period of time, the beaker has substrate, S, molecules only in the first section. Over the

period of time, the beaker has equal amounts of substrate molecules in both sections.

Return to An illustration shows the movement of substrate in a beaker from one section to the other over a period of time

Extended description for: An illustration shows the movement of substrate across a membrane to form complexes with enzyme molecules

The beaker is divided into two sections, 1 and 2. At the initial period of time, the beaker has substrate, S, molecules in the first section and enzyme, E, molecules in the second

section. Over a period of time, the beaker has only few substrate molecules in the first section and complex, E S, molecules in the second section. The E S complex molecule consists of a pair of enzyme and substrate molecules.

Return to An illustration shows the movement of substrate across a membrane to form complexes with enzyme molecules

Extended description for: Figure 14.5 Active site of an enzyme

The schematic model shows enzyme as an amorphous structure with a notch, labeled Active site, on its surface. It resembles a deep C in shape where the substrate gets attached.

The molecular model shows a 3-dimensional structure of catalase as an amorphous irregular solid with an active site on its surface, to which the substrate gets attached.

Return to Figure 14.5 Active site of an enzyme

Extended description for: Figure 14.6 Enzyme folding

The unfolded enzyme shows a long thread-like structure with small loops of varying lengths. One end has a C O O H group and the other has an N H subscript 2 group. Amino acids are on the surface of the loops. A

corresponding text reads: The amino acids that form the active site are often far apart in the linear sequence of the unfolded enzyme.

The folded enzyme shows a long, twisted coil with condensed loops. One end has a C O O H group and the other has an N H subscript 2 group. Amino acids on the surface of the coil are close to each other and linked to a bound substrate. A corresponding text reads: Protein folding brings specific amino acids close to each other to form the active site.

Return to Figure 14.6 Enzyme folding

Extended description for: Figure 14.7 Enzyme specificity

The chemical structure of lactose shows a six carbon hexagon ring. C 1 is single bonded to an oxygen atom on top and wedge bonded to C 2 which is single bonded to a hydroxyl group at the bottom; C 2 is double bonded to C 3 which is single bonded to a hydroxyl group on top; C 4 is single bonded to a

hydroxyl group at the top; and C 5 is single bonded to a hydroxyl methyl group on top. C 6 has an oxygen substituent single bonded to C 1. The single bonded oxygen of C 1 is further single bonded to the C 4 of another similar six carbon hexagon ring.

Lactase separates the two hexagon rings into separate six carbon hexagon rings of galactose and glucose. Both rings show C 1 single bonded to O H at top, C 2 single bonded to O H at bottom, C 3 single bonded to O H at top, and C 5 single bonded to C H 2 O H at top. The C 4 of galactose ring is single bonded to O H at top while C 4 of glucose ring is single bonded to O H at bottom.

Return to Figure 14.7 Enzyme specificity

Extended description for: Figure 14.8 Two models of enzyme–substrate interaction

(a) Lock and key model: A knob-shaped substrate fits perfectly into the similar shaped pocket in the enzyme.

(b) Induced fir model: A knob-shaped substrate binds to the pocket of the enzyme and the enzyme fill into the

remaining space to perfectly fit the key.

Return to Figure 14.8 Two models of enzyme–substrate interaction

Extended description for: Figure 14.9 Effect of temperature on enzyme activity

The horizontal axis represents temperature (in degree Celsius). The vertical axis represents rate of reaction. A curve starts from left side

of the horizontal axis, rises steadily to reach a peak, and drops down instantly at the right side of the horizontal axis. The peak is labeled, Optimal temperature.

Return to Figure 14.9 Effect of temperature on enzyme activity

Extended description for: Figure 14.10 Optimal temperatures for two enzymes

The horizontal axis represents temperature (in degree Celsius) and is labeled 31 and 72. The vertical axis represents rate of reaction. A curve for human enzyme starts from left side of the horizontal axis, rises

steadily to peak at 31 degree Celsius, and drops down instantly between 31 and 72 degree Celsius. The peak is labeled, Optimal temperature for human enzyme. A curve for bacterial enzyme starts slightly before 31 degree Celsius, rises steadily to peak at 72 degree Celsius, and drops down instantly after 72 degree Celsius. The peak is labeled, Optimal temperature for bacteria enzyme. Both peaks are equal in height.

Return to Figure 14.10 Optimal temperatures for two enzymes

Extended description for: Figure 14.11 Effect of pH on enzyme activity

The horizontal axis represents p H and ranges from 0 to 10, in increment of 1. The vertical axis represents rate of reaction. A bell-shaped curve for pepsin starts from 0, peaks at 2, and drops down to 3.5. The peak is labeled, Optimal p H for pepsin

(stomach enzyme). A bell-shaped curve for trypsin starts from 5.8, peaks at 8, and drops down to 10. The peak is labeled, Optimal p H for trypsin (intestinal enzyme).

Return to Figure 14.11 Effect of pH on enzyme activity

Extended description for: Figure 14.12 Competitive and non-competitive inhibition

(a) An enzyme-catalyzed reaction: A substrate fits into the active site of an

enzyme leading to the enzyme-substrate complex. This leads to an enzyme-product complex which finally releases the product from the active site.

(b) Competitive inhibition: A competitive inhibitor is bound to the the active site of the enzyme, blocking the attachment of substrate.

(c) Non-competitive inhibition: A non-competitive inhibitor is bound to an enzyme pocket opposite to the active site. The substrate binds to its respective active site forming an enzyme-substrate complex.

Return to Figure 14.12 Competitive and non-competitive inhibition

Extended description for: Figure 14.13 Regulation of threonine dehydratase, an allosteric enzyme

Threonine is converted to P 1 and the reaction is catalyzed by threonine dehydratase. P 1 proceeds to

sequentially form P 2, P 3, P 4, and then isoleucine in the final step. The end product, isoleucine, acts as an allosteric inhibitor for threonine dehydratase involved in the first step.

Return to Figure 14.13 Regulation of threonine dehydratase, an allosteric enzyme

Extended description for: Two scatterplots plot product versus substrate in experimental and control treatments

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In both graphs, the horizontal axis represents substrate [S] and is labeled low on left end and high on right end. The vertical axis represents product

[P] and is labeled low at bottom end and high at top end.

Graph (a) Experimental treatment: E and I added. Six data points are plotted on the graph in the shape of a positive concave-up curve starting from (low, low) and ending at (high, high).

Graph (b) Control: only E added. The graph also plots 6 data points. The first data point is plotted at (low, low) and the rest five data points are plotted in linear way from (low, high) to (high, high).

All data points, in both graphs, show vertical error bars.

Return to Two scatterplots plot product versus substrate in experimental and control treatments

Extended description for: A line graph plots product accumulated against time

The horizontal axis represents time (in hours) and ranges from 0 to 7, in increments of 1. The vertical axis represents product accumulated (in millimoles) and ranges from 0 to 30,

in increments of 5. A curve starts from (0, 0), extends vertically upward to (4.3, 25), and remains stable to end at (7, 25).

Return to A line graph plots product accumulated against time

Extended description for: Figure 15.5 Reduction

The flowchart has two parts: before and after reduction. The first part shows a carbon dioxide molecule. An arrow points from the molecule to an oval below that shows a carbon atom sharing a double bond with a single

oxygen atom. A caption reads: Electrons spend less time near carbon because carbon is less electronegative than oxygen. An arrow labeled “Reduction” leads to the second parts, which shows a model of a glucose molecule. A shaded oval below the glucose ring contains a single carbon to carbon bond. A caption reads: Carbon atoms share electrons equally, so carbon has partially gained electrons.

Return to Figure 15.5 Reduction

Extended description for: Figure 15.6 Oxidation

The flowchart has two parts: before and after oxidation. The first part shows a water molecule. An arrow points from this to an oval below that shows a hydrogen atom sharing a single bond with an oxygen atom. A caption reads: Electrons spend more time near oxygen because oxygen is

less electronegative than hydrogen. An arrow labeled Oxidation leads to the second part, showing an oxygen molecule. An arrow points to an oval below the oxygen molecule, which contains an oxygen atom double bonded to another oxygen atom. A caption reads: Oxygen atoms share electrons equally, so carbon has partially lost electrons.

Return to Figure 15.6 Oxidation

Extended description for: An illustration shows an experiment with Chlorella conducted to determine whether oxygen released by photosynthesis originates from water or carbon dioxide

A micrograph shows the green alga species Chlorella. Two arrows from it point to two test tubes below labeled initial. Step 1: Researchers placed Chlorella into two test tubes. The first test tube has H subscript 2 O left superscript 18 and C O subscript 2. The second test tube has H subscript 2 O and C O subscript 2 left superscript 18. Step 2: The tubes were exposed to sunshine for two

hours–;enough time for photosynthesis to occur.

Return to An illustration shows an experiment with Chlorella conducted to determine whether oxygen released by photosynthesis originates from water or carbon dioxide

Extended description for: Two graphs show the percentage of oxygen in each test tube from the experiment with Chlorella

Step 3: The percentage of O subscript 2 left superscript 18 in each tube was measured. The horizontal axis of each graph has two items, labeled initial and final. The vertical axis represents percent O subscript 2 left superscript 18 and ranges from 0 to 1.2 in

increments of 0.2. The data from first graph are as follows: Initial, 0.18 and Final, 0.85. The data from second graph are as follows: Initial, 0.19 and Final, 0.19. All data are approximate.

Return to Two graphs show the percentage of oxygen in each test tube from the experiment with Chlorella

Extended description for: Figure 15.7 Two stages of photosynthesis

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first part of the diagram, labeled

light reaction, shows sunlight falling on cross sections of plant cells, resembling stacks of flattened sacs sliced in half. A water molecule enters the cells and in the presence of sunlight produces an oxygen molecule while emitting an electron. Text reads, Oxidation of water, with O subscript 2 produced as a by-product. The emitted electron enters the photosynthetic electron transport chain. This results in A T P and N A D P H that enter the second part of the diagram, labeled Calvin cycle. During this cycle, a carbon dioxide molecule in the presence of A T P and N A D P H produces a carbohydrate molecule. Text reads, Reduction of C O subscript 2 to form carbohydrates.

Return to Figure 15.7 Two stages of photosynthesis

Extended description for: Figure 15.8 Chloroplast

Source: Biophoto Associates/Science Source
Morris, et al. *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A microscopic view of a densely packed chloroplasts inside plant cells is enlarged to show a chloroplast as a bean-shaped structure. The

chloroplast is surrounded by an outer and inner membrane enclosing fluid-like stroma. The stroma contains several membrane bound thylakoids consisting of a thylakoid membrane surrounding a thylakoid lumen. A stack of thylakoids is labeled grana.

Return to Figure 15.8 Chloroplast

Extended description for: Two line graphs titled, “Experiment performed in the light,” and two line graphs titled, “Experiment performed in the dark,” show production of oxygen and abundance of N A D P H

In all four graphs, the horizontal axis represents time (in hours) and ranges from 0 to 24 in increments of 4. The vertical axis represents percent of maximum level and ranges from 0 to 100 in increments of 20.

For the experiment performed in the light, oxygen production is a

horizontal line at 100 percent. In the first graph, titled No chloridation, the negatively sloped line for N A D P H abundance starts from (0, 99) and ends at (24, 95).

In the second graph, with chloridation applied, the negatively sloped curve for N A D P H abundance starts from (0, 100), drops down sharply around (5, 20), levels out around (12, 7) and ends at (24, 3).

For the experiment performed in the dark, the graphs are identical to each other and to the second graph of the experiment performed in the light with chloridation applied.

show production of oxygen and
abundance of N A D P H

Extended description for: Figure 16.1 The electromagnetic spectrum

The electromagnetic spectrum shows the following seven types of wavelengths from highest energy on the left to lowest energy on the right: gamma rays, X-rays, ultraviolet, visible light, infrared light,

microwaves, and radio waves. The visible light spectrum ranges from violet at 400 nanometers (shorter wavelengths on left) through indigo, blue, green, yellow, orange, and red at 700 nanometers (longer wavelengths on right).

Return to Figure 16.1 The electromagnetic spectrum

Extended description for: Figure 16.2 Light absorbed by leaves

A visible light spectrum is depicted above an illustration of a leaf. The spectrum ranges from violet at 400 nanometers (shorter wavelength on

left) to red at 700 nanometers (longer wavelength on right). A line graph below the spectrum shows absorption on the vertical axis. The curve corresponding to the visible spectrum starts from medium absorption, rises to a crest at around 480 nanometers, falls to a trough around 550 nanometers, then rises to a second peak around 650 nanometers.

Return to Figure 16.2 Light absorbed by leaves

Extended description for: Figure 16.3 Absorption spectra of individual pigments

The horizontal axis represents wavelength of light in nanometers and ranges from 400 to 700 in increments of 100. The vertical axis represents absorption. The curve for

carotenoid starts from (400, low absorption), peaks at (475, high absorption), and ends at (525, no absorption). The curve for chlorophyll a starts from (400, medium absorption), peaks at (425, high absorption), drops down to (460, no absorption), remains at very low absorption till 600, peaks again at (675, medium absorption), and ends at (700, no absorption). The curve for Chlorophyll b starts from (400, low absorption), peaks at (450, high absorption), drops down to (475, very low absorption), remains at very low absorption till 620, slightly peaks again at (630, medium absorption), and ends at (675, no absorption). From 400 to 500 nanometers, the peak

of chlorophyll b is highest and that of carotenoid slightly higher than chlorophyll a. From 600 to 700 nanometers, the peak of chlorophyll a is higher than chlorophyll b.

Return to Figure 16.3 Absorption spectra of individual pigments

Extended description for: Figure 16.4 Absorption of light energy by chlorophyll in the lab

The flowchart shows a chlorophyll molecule with a ground-state electron. A rightward arrow showing the addition of light leads to a

chlorophyll molecule with an excited-state electron. Another rightward arrow showing loss of heat and fluorescence leads to the chlorophyll molecule with a ground-state electron. The corresponding graph below the flowchart shows energy on the vertical axis. The bars for both ground-state electrons show low energy levels while the bar for the excited-state electron has a high energy level.

Return to Figure 16.4 Absorption of light energy by chlorophyll in the lab

Extended description for: Figure 16.5 Absorption of light energy by chlorophyll in a plant cell

The flowchart shows a chlorophyll molecule with a ground-state electron. A rightward arrow showing

the addition of light leads to a chlorophyll molecule with an excited-state electron. Another rightward arrow leads to the chlorophyll molecule with a ground-state electron. A downward arrow from second rightward arrow, labeled energy transfer, shows a chlorophyll molecule with a ground-state electron leading to the chlorophyll molecule with an excited-state electron.

Return to Figure 16.5 Absorption of light energy by chlorophyll in a plant cell

Extended description for: Figure 16.6 The reaction center

Part (a): Oxidation of the reaction center. Light hits a series of antenna chlorophyll molecules and is transferred to the reaction center, where electrons become excited. The excited-state electron is then transferred to an electron acceptor molecule.

Part (b): Reduction of the reaction center. A ground-state electron from the electron donor is transferred to a reaction center that has lost an electron.

Return to Figure 16.6 The reaction center

Extended description for: Figure 16.7 Two photosystems

The illustration shows photosystem 2 and photosystem 1 embedded in the thylakoid bilayer. Each photosystem shows a series of antenna chlorophylls attached to a reaction center. A molecule of water breaks into an oxygen atom and hydrogen

ion while emitting an electron. The electron enters the chlorophyll molecule of the photosystem 2 reaction center. When light hits this system of antenna molecules, the electron becomes excited and is transferred along the transport chain. Along the transport chain, the electron changes to ground-state and is transferred to photosystem 1. When light hits this system of antenna molecules, the electron becomes excited and combines positively charged N A D P plus hydrogen ion to produce N A D P H.

Return to Figure 16.7 Two photosystems

Extended description for: Figure 16.8 The Z scheme

The illustration shows light hitting on photosystem 2 and photosystem 1, shown as irregular proteins embedded in the thylakoid bilayer.

The corresponding graph shows energy on the vertical axis. The line on the graph maps the energy levels in the shape of a Z, rotated 90 degrees, where the two vertical lines correspond to the photosystems. As light is absorbed by photosystem 2, the energy level increases. Between photosystem 2 and photosystem 1, the energy decreases linearly to slightly above its initial energy, before ascending vertically again at photosystem 1.

Return to Figure 16.8 The Z scheme

Extended description for: Figure 16.9 Electron transport, proton accumulation, and ATP synthesis

The membrane is present between the stroma and the thylakoid space, which is depicted with many suspended molecules. It consists of a bilayer with large embedded proteins. H superscript positive passes from

the stroma through the membrane to the thylakoid space. Light from the stroma enters photosystems 2 and 1 along the membrane. H subscript 2 O from the thylakoid space is broken down into O subscript 2 and H superscript positive, emitting an electron that enters photosystem 2. From here, the electron travels to photosystem 1, then to the stroma, where it combines with N A D P superscript positive plus H superscript positive to form N A D P H. A T P synthase present at the end of the membrane shows the transfer of H superscript positive from the thylakoid space to the stroma. Simultaneously, A T P synthase converts A D P plus P subscript i into

A T P on the stroma side.

Return to Figure 16.9 Electron transport, proton accumulation, and ATP synthesis

Extended description for: Figure 16.10 The Calvin cycle

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A simplified drawing of a chloroplast shows the Calvin cycle inside it. The enlarged Calvin cycle reads as follows:

C O subscript 2 input: Carbon enters the Calvin cycle as C O subscript 2

and reacts with ribulose 1, 5-bisphosphate (R u B P). Step 1: Fixation: The addition of C O subscript 2 to the 5-carbon compound, R u B P, is catalyzed by the enzyme rubisco. This leads to two 3-carbon molecules. Step 2: Reduction: Energy inputs from A T P and N A D P H lead to the synthesis of triose phosphate. During this step, A T P is converted to A D P and N A D P H is converted to N A D P superscript positive plus electron. This leads to triose phosphate. Step 3: Carbohydrate output: triose phosphates are converted to glucose. Step 4: Regeneration of R u B P: In this multistep process, 3-carbon compounds are reorganized and

combined to produce R u B P. This leads back to ribulose 1, 5-bisphosphate (R u B P).

Return to Figure 16.10 The Calvin cycle

Extended description for: Figure 16.12 Photorespiration

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A drawing of a simplified chloroplast shows the cycles inside it. A circular flowchart on the left shows photorespiration and a circular flowchart on the right shows photosynthesis (Calvin cycle). The two cycles are connected by rubisco, ribulose 1, 5-bisphosphate (R u B P).

Text reads, Rubisco can use oxygen or carbon dioxide as a substrate. In photorespiration, O subscript 2 combines with R u B P and yields C O subscript 2. Text reads, In photorespiration, A T P is consumed and carbon dioxide is produced. In photosynthesis (Calvin cycle), C O subscript 2 combines with R u B P and yields carbohydrates. Text reads, In photosynthesis, A T P is produced in the light reactions, and carbon dioxide is consumed in the Calvin cycle.

Return to Figure 16.12 Photorespiration

Extended description for: A line graph shows the Z scheme with four steps

The vertical axis represents energy and is labeled low at the bottom and high at the top. An arrow labeled 1, points from P S 2 near the origin of the graph vertically up to the mid-high range on the vertical axis. A

series of arrows labeled 2, points downward and to the right to P S 1, which is slightly higher than P S 2, and from which an arrow labeled 3 points vertically up to a high point on the vertical axis. A series of arrows labeled 4, points downward and to the right.

Return to A line graph shows the Z scheme with four steps

Extended description for: Figure 17.2 Oxidation

A Lewis diagram of a glucose molecule appears at the top left of the diagram. A shaded oval below the glucose ring shows a single carbon to carbon bond. An arrow labeled Oxidation points from the glucose to a carbon dioxide molecule. An oval below the carbon dioxide molecule

shows a carbon atom sharing a double bond with a single oxygen atom. The side of the oval near the oxygen atom is more darkly shaded than the rest. A caption reads, Dark shading represents increased electron density.

Return to Figure 17.2 Oxidation

Extended description for: Figure 17.3 Reduction

An oxygen molecule appears at the top left. The oval below the oxygen shows two oxygen atoms sharing a double bond. Electron density is even around the perimeter of the oval. An arrow labeled reduction points from the oxygen molecule to a water molecule. An oval below the water

molecule shows a hydrogen and oxygen molecule sharing a single bond. The electron density is greater in the vicinity of the oxygen.

Return to Figure 17.3 Reduction

Extended description for: Figure 17.4 ATP production in cellular respiration

A carbohydrate molecule undergoes oxidation to yield carbon dioxide. Two

arrows extend from the process of oxidation. One arrow, labeled substrate-level phosphorylation, leads to A T P. The second arrow leads to electron carriers, which then lead to A T P via the respiratory electron transport chain. The arrow from electron carriers to A T P is labeled oxidative phosphorylation, and during this process oxygen is added and water is produced as a byproduct.

Return to Figure 17.4 ATP production in cellular respiration

Extended description for: Figure 17.5 The four stages of cellular respiration

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The four stages are as follows:

Stage 1: Glycolysis: Glucose is broken down to pyruvate, producing A T P, highlighted in yellow, and reduced

electron carriers.

Stage 2: Pyruvate oxidation: Pyruvate is converted to acetyl Co A, producing reduced electron carriers and C O subscript 2.

Stage 3: Krebs cycle: Acetyl Co A enters the Krebs cycle, producing A T P, which is highlighted in yellow, reduced electron carriers, and C O subscript 2.

Stage 4: Oxidative phosphorylation: Electron carriers donate electrons to the electron transport chain, leading to the synthesis of A T P. During this process, oxygen is converted to water.

Return to Figure 17.5 The four stages

of cellular respiration

Extended description for: Figure 17.6 Change in free energy in each step of cellular respiration

The vertical axis represents change in free energy, delta G, in kilocalories per mole and ranges from negative

700 to 0, in increments of 100. The graph shows three vertically shaded regions, glycolysis, pyruvate oxidation, and Krebs cycle. The stepped line graph traces the changes in the catabolism of a single molecule of glucose. The line takes six small steps upward from zero during the glycolysis stage, in which two molecules of A T P are utilized in the first and third steps. This shows a small increase in the delta G of glucose. Then the line drops down to negative 100, producing N A D H and two A T P molecules. The point at which the glycolysis reaction produces pyruvate is when the pyruvate oxidation stage begins, and the delta G of glucose drops to

between negative 200 and 300 kilocalories per mole. This is the point where acetyl C o A is produced, along with one N A D H, and enters the Krebs cycle. The delta G continues to drop as the coenzyme molecule is broken down in the cycle. This process produces three N A D H, one F A D H subscript 2, and one A T P. At this point, the delta G of the reaction is just under negative 650 kilocalories per mole.

Extended description for: Figure 17.7 Storage forms of glucose

Illustration (a) glycogen: Glycogen is a large, branched chain of glucose molecules attached to a central protein. The illustration shows several strings and branches of beads arranged around a central protein in

a circle. Illustration (b) starch: Starch is a large, branched chain of glucose molecules found in plants such as potatoes, wheat, and corn. The illustration shows a smaller, simpler, and more orderly version of the glycogen molecule.

Return to Figure 17.7 Storage forms of glucose

Extended description for: Figure 17.8 Common sugars in the diet

Six sugars in total are presented, the name of each is depicted above its structural formula. Under disaccharides are lactose found in milk; maltose found in barley; and sucrose found in candy. Each of these has a double ring structure, which is

held together by a single oxygen atom.

Lactose and maltose look nearly identical, each having two hexagonal carbon rings, 8 hydroxyl groups, and 4 hydrogen atoms each. The only difference is that the maltose rings are arranged horizontally, and the lactose rings are arranged vertically. Sucrose has a hexagonal and a pentagonal ring joined by a single oxygen atom. The hexagonal ring has six hydrogens and four hydroxyl groups attached. The pentagonal ring of sucrose's formula has five hydrogens and five hydroxyl groups attached.

Under monosaccharides are galactose, also found in milk, and fructose and mannose, which are found in fruit. The structural formulae for galactose and mannose are both hexagonal, each containing five hydroxyl groups and two hydrogen atoms. The structural formula for fructose is pentagonal, with five hydroxyl groups and four hydrogens attached.

Return to Figure 17.8 Common sugars in the diet

Extended description for: Figure 17.9 Other fuel molecules

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The cellular respiration process shows the following four stages:

Stage 1: Glycolysis: Glucose is broken down to pyruvate, producing A T P.

Stage 2: Pyruvate oxidation: Pyruvate is converted to acetyl Co A, producing reduced electron carriers and C O subscript 2.

Stage 3: Krebs cycle: Acetyl Co A enters the Krebs cycle, producing A T P, reduced electron carriers, and C O subscript 2.

Stage 4: Oxidative phosphorylation: Electron carriers donate electrons to the electron transport chain, leading to the synthesis of A T P. During this

process, oxygen is converted to water.

Proteins are broken down into amino acids and triacylglycerols are broken down into fatty acids and glycerol. Amino acids can be converted to pyruvate or directly converted to acetyl Co A or enter the Krebs cycle. Fatty acids are directly converted to acetyl Co A. Glycerol along with other carbohydrates enters the Stage 1, Glycolysis step.

Return to Figure 17.9 Other fuel molecules

Extended description for: Six line graphs in two rows and three columns show biological properties of two strains, A and B

Strain A is depicted in the top row and strain B in the bottom row. Column headers are glucose only, lactose only, and no sugar. The horizontal axis of all graphs represents time (in hours)

and ranges from 0 to 24 in increments of 6. The vertical axis represents number of cells and ranges from 10 squared to 10 to the power of 5 in multiples of 10. The data reads as follows:

Strain A, Glucose only: The positive curve starts from (0, 20), steeply rises to (18, 90000), and plateaus to end at (24, 90000).

Strain A, Lactose only: The positive curve starts from (0, 20), steeply rises to (18, 90000), and plateaus to end at (24, 90000).

Strain A, No sugar: The horizontal slope starts from (0, 400) and ends at (24, 400).

Strain B, Glucose only: The positive curve starts from (0, 20), steeply rises to (18, 90000), and plateaus to end at (24, 90000).

Strain B, Lactose only: The horizontal slope starts from (0, 400) and ends at (24, 400).

Strain B, No sugar: The horizontal slope starts from (0, 400) and ends at (24, 400).

All data are approximate.

Return to Six line graphs in two rows and three columns show biological properties of two strains, A and B

Extended description for: Figure 18.1 Glycolysis

A small flowchart on the top left corner shows the four steps of

cellular respiration as follows: Glucose is converted to pyruvate during glycolysis, producing electrons and A T P; pyruvate is converted to acetyl Co A, producing C O 2 and electrons; Acetyl Co A undergoes Krebs cycle, producing C O 2, A T P, and electrons; and all the electrons are transported by electron carriers to electron transport chain, producing A T P and simultaneously converting O 2 to C O 2. The Glycolysis step is highlighted to show its three phases.

Phase 1: Preparatory phase, with consumption of 2 A T P. During this phase, the (6 C) glucose is converted to (6 C) fructose 1, 6-bisphosphate by converting 2 A T Ps to 2 A D Ps.

Phase 2: The cleavage phase 5. During this phase, the (6 C) fructose 1, 6-bisphosphate is cleaved into (3 C) glyceraldehyde 3-phosphate and (3 C) dihydroxyacetone phosphate.

Phase 3: Payoff phase, with production of 4 A T P and 2 N A D H. During this phase, the (3 C) glyceraldehyde 3-phosphate is converted to (3 C) pyruvate by converting N A D plus to N A D H and A D P to A T P. The (3 C) dihydroxyacetone phosphate is also converted to (3 C) pyruvate by converting N A D plus to N A D H and A D P to A T P.

Return to Figure 18.1 Glycolysis

Extended description for: Figure 18.3 Pyruvate oxidation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A small flowchart on the left shows the four steps of cellular respiration as follows: Glucose is converted to pyruvate during glycolysis, producing electrons and A T P; pyruvate is converted to acetyl Co A, producing C

O 2 and electrons; Acetyl Co A undergoes Krebs cycle, producing C O 2, A T P, and electrons; and all the electrons are transported by electron carriers to electron transport chain, producing A T P and simultaneously converting O 2 to C O 2. The pyruvate oxidation step is highlighted as follows:

The pyruvate molecule present in cytosol is transported into the mitochondrial matrix, across the intermembrane space. During the transport, pyruvate is converted to acetyl Co A by utilizing Coenzyme A. Simultaneously, N A D plus is converted to N A D H and C O 2 is released. The acetyl group attached to

the coenzyme a molecule consists of a ketone group attached to a methyl group.

Return to Figure 18.3 Pyruvate oxidation

Extended description for: Figure 18.4 The Krebs cycle

A small flowchart on the top left corner shows the four steps of cellular respiration as follows: Glucose is converted to pyruvate during glycolysis, producing electrons

and A T P; pyruvate is converted to acetyl Co A, producing C O 2 and electrons; Acetyl Co A undergoes Krebs cycle, producing C O 2, A T P, and electrons; and all the electrons are transported by electron carriers to electron transport chain, producing A T P and simultaneously converting O 2 to C O 2. The Krebs cycle is highlighted as follows:

A single molecule of acetyl-coenzyme A enters the cycle and combines with a 4 C oxaloacetate to produce a 6 C citric acid. The 6 C citric acid is converted to a 6 C molecule which is further converted to a 5 C molecule, while simultaneously converting N A D plus to N A D H and releasing C O 2.

The 5 C molecule is converted to a 4 C molecule, while simultaneously converting N A D plus to N A D H and releasing C O 2. The 4 C molecule is again converted to a 4 C molecule, while simultaneously converting A D P plus P i to A T P. This 4 C molecule is again converted to another 4 C molecule, while simultaneously converting F A D to F A D H 2. This 4 C molecule is again converted to a 4 C molecule and then to a 4 C oxaloacetate, while simultaneously converting N A D plus to N A D H. This 4 C oxaloacetate leads back to the starting of the cycle.

Return to Figure 18.4 The Krebs cycle

Extended description for: Figure 18.5 The respiratory electron transport chain

Morris, et al, Biology for the AP® Course, 1e, © 2023 BFW High School Publishers

Four complexes (1 to 4) and an A T P synthase, span the inner membrane, separating mitochondrial matrix from intermembrane space. An upward arrow labeled Proton concentration gradient illustrates high H plus concentration in intermembrane

space and low H plus concentration in mitochondrial matrix. Electrons donated by N A D H and F A D H 2 enter through complex 1 and complex 2, respectively. A proton is pumped into the intermembrane space through complex 1 and complex 4. The electron from complex 1 and 2 passes through the inner membrane to complex 3, then an electron from complex 3 passes through the intermembrane space to complex 4. The electron from complex 4 points to an oxygen which reacts with four protons to yield two molecules of water. An A T P synthase enzyme pumps out a proton to the mitochondrial matrix. It is also the site where A D P becomes A T P.

Complexes 1 and 2 harvest electrons from N A D H and F A D H 2. The transport of electrons in complexes 1, 3, and 4 are coupled with the transport of protons across the inner membrane, from the mitochondrial matrix to the intermembrane space. A T P synthase uses the electrochemical proton gradient to drive the synthesis of A T P.

Return to Figure 18.5 The respiratory electron transport chain

Extended description for: Figure 18.6 ATP synthase

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A unit of A T P synthase is embedded in the mitochondrial membrane separating the intermembrane space and mitochondrial matrix. This structure resembles a dumbbell, with two heads that appear to each be made of several oblong, pill-like structures. The bottom head is in the mitochondrial membrane and forms a channel, which rotates as protons pass through it. Positively charged hydrogen atoms are allowed to pass outside the cell membrane through this process. The other head is the A T P synthase unit and extends into the mitochondrial matrix, using the rotational energy to catalyze the synthesis of A T P, illustrated as a single unit of inorganic phosphate

bonding with an A D P molecule.

Return to Figure 18.6 ATP synthase

Extended description for: An illustration shows the Racker and Stoeckenius' A T P synthesis system

Racker and Stoeckenius' device is made of three major components: a circular bilayer cell membrane, a unit

of A T P synthase embedded in the membrane, and a bacterial proton pump, which was activated by light, illustrated by a bulb. Inside the cell membrane, several proton are depicted, which enter through the bacterial proton pump and exit through the A T P synthase. A T P is produced from A D P and an inorganic phosphate on the exterior of the A T P synthase.

Return to An illustration shows the Racker and Stoeckenius' A T P synthesis system

Extended description for: A line graph shows the concentration of protons in the presence of light, as measured in Racker's and Stoeckenius' A T P synthesis experiment

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The vertical axis is labeled p H of external medium. When the light is turned on, proton levels inside the vesicle are surged. This is reflected by the fact that the line on the graph is vertical, before curving almost 90 degrees near the top and leveling off. When the light is turned off, the line reflects that proton levels are crashed. It falls vertically, curving more gradually down near the horizontal axis until it reaches starting levels.

Return to A line graph shows the concentration of protons in the presence of light, as measured in Racker's and Stoeckenius' A T P synthesis experiment

Extended description for: A line graph shows mass of ions H plus against mass of purple protein ions

The horizontal axis is labeled Mass of purple protein ions (in micrograms)

and ranges from 0 to 100, in increments of 20. The vertical axis is Mass of ions, H plus, (in nanograms) and ranges from 0 to 10, in increments of 1. A positive slope starts from (0, 0) and ends at (100, 8.2). Points scattered near the line are plotted as follows: (5, 0.5), (12, 0.9), (25, 1.9), (30, 2.3), (50, 3.9), and (100, 8.5). All data are approximate.

Return to A line graph shows mass of ions H plus against mass of purple protein ions

Extended description for: Figure 18.7 Total ATP production in cellular respiration

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The flow of energy in cellular respiration begins with a single

molecule of glucose inside the cell membrane. During the glycolysis process, the reaction generates electron carriers (2 molecules each of N A D H) and A T P, and produce pyruvate. The pyruvate oxidation, occurring inside mitochondrial matrix, produces Acetyl Co A and generates electron carriers (2 molecules each of N A D H). The Acetyl Co A enters Krebs cycle and generates electron carriers (6 molecules each of N A D H and 2 molecules of F A D H 2) and 2 AT P molecules. All the electron carriers undergo oxidative phosphorylation at the inner mitochondrial membrane and generate 28 A T P molecules. Overall, total 32 A T P molecules are

generated in the entire process.

Return to Figure 18.7 Total ATP production in cellular respiration

Extended description for: Figure 18.8 Lactic acid fermentation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The ring structure of glucose is depicted above the first step of the lactic acid fermentation process. An

arrow, signifying glycolysis, points downward toward the structural formula for pyruvate. A molecule of pyruvate is produced and a molecule of A D P bonds with a phosphate group to create A T P. An arrow curves upward from pyruvate to the structural formula of lactic acid. A central carbon atom is attached to a carboxyl group, a hydroxyl group, a methyl group, and a single hydrogen. Before this process can be completed, the molecule of N A D H produced by glycolysis, bonds with a positively-charged hydrogen ion, which starts the fermentation process necessary to form lactic acid. This bond produces positively-charged N A D, which in turn is used to complete the

process of glycolysis.

Return to Figure 18.8 Lactic acid fermentation

Extended description for: Figure 18.9 Ethanol fermentation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The ring structure of glucose is depicted above an arrow signifying

glycolysis, which points downward toward a pyruvate molecule. As with lactic acid fermentation, this process produces A T P in the same manner. The conversion of N A D H into positively-charged N A D via the hydrogen cation is also the same. The only difference is that, to create ethanol, the pyruvate must first be converted into acetaldehyde. This conversion also produces carbon dioxide. From here, it is fermented into ethanol, whose structural formula is depicted. A central hydrocarbon shares a single bond each with a hydroxyl group and a methyl group.

Return to Figure 18.9 Ethanol

fermentation

Extended description for: A flowchart shows the steps of glycolysis

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Step 1: Hexokinase converts Glucose to Glucose 6-phosphate. During the

process, A T P becomes A D P.

Step 2: Phosphoglucose Isomerase converts Glucose 6-phosphate to Fructose 6-phosphate.

Step 3: Phosphofructokinase-1 converts Fructose 6-phosphate to Fructose 1,6-biphosphate. During the process, A T P becomes A D P.

Step 4: Adolase converts Fructose 1,6-biphosphate to Dihydroxyocetone phosphate and Glyceraldehyde 3-phosphate (2 molecules).

Step 5: Triose phosphate isomerase converts Dihydroxyocetone phosphate to Glyceraldehyde 3-phosphate (2 molecules).

Step 6: Glyceraldehyde 3-phosphate dehydrogenase converts Glyceraldehyde 3-phosphate (2 molecules) to 3-Phosphoglycerate (2 molecules). During the process, 2 N A D superscript positive plus 2 P subscript i becomes 2 N A D H plus 2 H superscript positive.

Step 7: Phosphoglycerate kinase converts 3-Phosphoglycerate (2 molecules) to 2-Phosphoglyverate (2 molecules). During the process, 2 A D P becomes 2 A T P.

Step 8: Phosphoglyceromutase converts 2-Phosphoglyverate (2 molecules) to Phosphoenolpyruvate (2 molecules).

Step 9: Enolase converts Phosphoenolpyruvate (2 molecules) to Phosphoenolpyruvate (2 molecules). A product of this step is 2 H subscript 2 O.

Step 10: Pyruvate kinase converts Phosphoenolpyruvate (2 molecules) to Pyruvate (2 molecules). During the process, 2 A D P becomes 2 A T P.

All steps are reversible, except step 1.

Return to A flowchart shows the steps of glycolysis

Extended description for: An illustration shows the process of photosynthesis. An illustration shows the process of cellular respiration

Morris, et al., Biology for the AP® Course, 1e, © 2022 BFW High School Publishers

Photosynthesis: Energy captured from sunlight is stored in

carbohydrates. There are two diagrams on the top. The first is the simplified version of the electron transport chain, and the second is the simplified Calvin cycle. Both of these are processes that occur inside the chloroplast. The link between these two figures is the N A D P H produced during photosynthesis. This is necessary for the production of carbohydrates in the Calvin cycle. A diagram below breaks down the processes into simple terms. The photosynthetic electron transport chain has three steps listed before linking to the Calvin cycle. The first step shows water and sunlight as inputs into the chlorophyll inside Photosystem 2. This produces outputs

of oxygen gas, hydrogen ions, and electrons. The electron is then transferred to the second step, the cytochrome b 6 f complex, then into the chlorophyll inside Photosystem 1, where sunlight helps facilitate the production of A T P and N A D P H, at which point the Calvin cycle begins. Carbon dioxide and A T P are the inputs into the Calvin cycle, which produces A D P and carbohydrates. A caption for the electron transport chain reads, photosynthesis requires light energy, carbon dioxide, and water, and produces carbohydrates and oxygen. The light reactions use energy from sunlight to drive the movement of electrons from water to N A D P plus along a photosynthetic

electron transport chain, producing N A D P H and A T P. A caption for the Calvin cycle reads, Carbon dioxide is reduced by N A D P H and, using the energy provided by A T P, is incorporated into a carbohydrate molecule in the Calvin cycle.

Cellular respiration: Energy released from the oxidation of carbohydrates is used to make A T P. Side by side diagrams, which are simplified versions of the glycolysis, pyuvate oxidation, and the Krebs cycle loop, are depicted next to the diagram of the oxidative phosphorylation that occurs inside a mitochondrion. The molecules of N A D H and F A D H 2 produced in glycolysis and the Krebs

cycle are needed to facilitate the transport of oxygen, the creation of water, and the synthesis of A T P inside the mitochondria. The diagrams underneath these break down the graphic representation of the processes above into simple terms. The two steps in glycolysis are a starting carbohydrate, and pyruvate made from said carbohydrate; this occurs in the stroma. A D P is converted into A T P during this process, and pyruvate produces carbon dioxide as it is broken down into acetyl-coenzyme A and enters the Krebs cycle in the mitochondrion. A D P is the input into the Krebs cycle, which produces N A D P and F A D H 2. These substances are necessary to

begin the electron transport chain (oxidative phosphorylation) and are transported into Complexes 1 and 2, respectively. The electron transport chain has three steps listed after the two molecules enter the complexes. They are moved into Complex 3, then Complex 4, which facilitates the conversion of A D P into A T P by the A T P synthase, as well as the creation of water, which itself is powered by electrons. The F A D H 2 and N A D H produced in the Krebs cycle is taken up by complex 2 and complex 1 in the electron transport chain, respectively. In the process, complex 1 produces positive N A D and complex 2 produces FA D. A caption for glycolysis reads: Cellular respiration

requires carbohydrates and O 2 and produces C O 2, H 2 O, and A T P. Glycolysis splits glucose into two molecules of pyruvate and begins the oxidation of organic molecules. A caption for pyuvate oxidation reads: Pyruvate oxidation continues the oxidation process, with the production of acetyl-Co A. A caption for Krebs cycle reads: The Krebs cycle completes the oxidation of organic molecules. A caption for oxidative phosphorylation reads: Oxidative phosphorylation involves the transfer of electrons along the electron transport chain to oxygen, which in turn generates a proton gradient that powers the production of A T P by A T P synthase.

Extended description for: Four bar graphs labeled (a) through (d) plots C O 2 consumptions against temperature

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In all graphs, vertical axis represents CO_2 consumption (in micro moles per second) and ranges from 0 to 120, in increments of 20. The horizontal axis in graph A and B represents temperature (in degree Celsius) and ranges from 25 to 50, in increments of 5. The data are as follows:

Graph A: (25, 59) with vertical error bar from 58 to 62; (30, 70) with vertical error bar from 63 to 79; (35, 90) with vertical error bar from 83 to 100; (40, 92) with vertical error bar from 87 to 100; (45, 95) with vertical error bar from 90 to 100; and (50, 105) with vertical error bar from 98 to 112.

Graph B: (25, 90) with vertical error

bar from 83 to 100; (30, 95) with vertical error bar from 90 to 100; (35, 90) with vertical error bar from 83 to 100; (40, 105) with vertical error bar from 98 to 112; (45, 70) with vertical error bar from 63 to 79; and (50, 59) with vertical error bar from 58 to 62.

Graph C: The horizontal axis represents temperature (in degree Celsius) and is labeled 50, 45, 25, 35, 30, and 40. The data are as follows: (50, 59) with vertical error bar from 58 to 62; (45, 70) with vertical error bar from 63 to 79; (25, 90) with vertical error bar from 83 to 100; (35, 92) with vertical error bar from 87 to 100; (30, 95) with vertical error bar from 90 to 100; and (40, 105) with vertical error

bar from 98 to 112.

Graph D: The horizontal axis represents temperature (in degree Celsius) and is labeled 45, 35, 40, 35, 25, and 50. The data are as follows: (45, 70) with vertical error bar from 63 to 79; (35, 92) with vertical error bar from 87 to 100; (40, 105) with vertical error bar from 98 to 112; (35, 95) with vertical error bar from 90 to 100; (25, 90) with vertical error bar from 83 to 100; and (50, 59) with vertical error bar from 58 to 62.

All data are approximate.

Return to Four bar graphs labeled (a) through (d) plots C O 2 consumptions against temperature

Extended description for: A line graph plots product versus time at 25, 37, and 50 degree Celsius

The horizontal axis represents time (in seconds) and ranges from 0 to 150, in increments of 15. The vertical axis represents product P (in nanomoles) and ranges from 0 to 50, in increments of 10. The horizontal

slope for 50 degree Celsius starts from (0, 0) and ends at (150, 0). The positive curve for 37 degree Celsius starts from (0, 0), steadily increases to (120, 45), and remains stable to end at (150, 45). The positive curve for 25 degree Celsius starts from (0, 0), steadily increases to (75, 45), and remains stable to end at (150, 45). All data are approximate.

Return to A line graph plots product versus time at 25, 37, and 50 degree Celsius

Extended description for: A flowchart shows the steps of lipid biosynthesis

In the Krebs cycle, malate is converted to oxaloacetate by malate dehydrogenase. The oxaloacetate gets converted to citric acid by citrate synthase which leads back to malate. During the conversion of oxaloacetate to citric acid, the citrate synthase also

interacts with Acetyl-Co A and Co A-S H. The Acetyl-Co A gets converted to Malonyl-Co A by Acetyl-Co A carboxylase. The Malonyl-Co A finally leads to lipid biosynthesis.

Return to A flowchart shows the steps of lipid biosynthesis

Extended description for: Figure 20.1 Communication in birds

Panther Media GmbH/Alamy Stock Photo
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In the photo, the parent bird has an insect in its beak. The young bird stretches its mouth toward the food. The flowchart reads as follows: Stimulus (hunger) leads to signal sent

(begging behaviors) which leads to signal received (parent sees begging). This finally leads to response (parent provides food).

Return to Figure 20.1 Communication in birds

Extended description for: Figure 20.4 Communication by quorum sensing among bacterial cells

Illustration A, bacterial population at low density, shows three bacterial

cells, each with three Y-shaped receptor proteins. The background shows a few scattered signaling molecules. An enlarged view of one of the cells shows that it is receiving a signaling molecule. Text beside the diagram reads: “At low population density, the concentration of the signaling molecule is too low to bind to the receptors, so these bacteria do not glow.”

Illustration B, bacterial population at high density, shows several bacterial cells and abundant signaling molecules. Text beside the diagram reads: “At high population density, the abundant signaling molecules bind to receptors, so these bacteria glow.”

Return to Figure 20.4 Communication by quorum sensing among bacterial cells

Extended description for: Figure 20.5 Communication among cells in a multicellular organism

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows a human torso with internal organs labeled. Adrenal

glands present above the kidneys release adrenaline. Arrows from adrenaline point to the lungs, heart, stomach, and kidneys. Text beside the adrenal glands reads: “Adrenaline is a signaling molecule released by cells of the adrenal glands.” Text beside the lungs reads: “Adrenaline binds to receptors on cells of the heart and many other organs, leading to a response.”

Return to Figure 20.5 Communication among cells in a multicellular organism

Extended description for: Figure 20.6 Signaling distances

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Illustration A shows endocrine signaling. The signaling cell sends signaling molecules through the circulatory system. When they come in contact with a receptor cell, they

bind to the receptor proteins. Illustration B shows paracrine signaling, where the signaling cell lies adjacent to target cell and sends signaling molecules through the gap between them. Illustration C shows autocrine signaling, in which the signaling molecules bind to the sending cell's own receptor proteins.

Return to Figure 20.6 Signaling distances

Extended description for: Figure 20.8 Gap junctions

The illustration shows several nucleated animal cells with a group of pink dots (gap junctions) on the wall of a cell. The dots are circled and point to an enlarged view of two neighboring call walls. The neighboring cells are connected by a cluster of tubule-like gap junctions

across the cell membranes and intercellular space. Text reads, “gap junctions are intercellular connections made up of a ring of proteins.”

Return to Figure 20.8 Gap junctions

Extended description for: Figure 20.9 Plasmodesmata

The illustration shows plant cells, and an enlarged view shows the plasmodesmata. A micrograph shows the cell interiors of two adjacent cells separated by cell membranes and cell walls. The interiors of the two cells

are connected by plasmodesmata, represented as dark lines on the micrograph and as gaps between rectangular shaped sections cell walls in the enlargement. Tissues of endoplasmic reticulum extend through the plasmodesmata between the cells. Text reads, “Plasmodesmata are intercellular connections lined by extensions of the cell membrane. They also contain a tubule connecting the endomembrane systems of neighboring cells.”

Return to Figure 20.9 Plasmodesmata

Extended description for: Figure 20.10 Temperature regulation by negative feedback in a home heating system

Cold, labeled stimulus, acts on a

thermostat, labeled sensor, which shows a temperature of 18 degrees Celsius. The thermostat communicates with a heater, labeled effector, that produces heat, labeled response. This feeds back to the thermostat.

Return to Figure 20.10 Temperature regulation by negative feedback in a home heating system

Extended description for: Figure 20.11 Temperature regulation by negative feedback in a human

Cold, labeled stimulus, acts on the hypothalamus, labeled sensor, which is located in the brain. The hypothalamus communicates with muscles, labeled effector, which

induces shivering and produces heat, labeled response, which in turn sends negative feedback signals back to the hypothalamus.

Return to Figure 20.11 Temperature regulation by negative feedback in a human

Extended description for: Figure 20.12 Blood glucose regulation by negative feedback

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

An increase in blood glucose levels acts on the pancreas. Accompanying text reads, “Pancreas cells secrete insulin.” The pancreas communicates with target cells. Accompanying text reads, “Target cells increase glucose uptake.” The target cells result in a decrease in blood glucose levels, which in turn sends negative feedback signals to the pancreas.

Return to Figure 20.12 Blood glucose regulation by negative feedback

Extended description for: A diagram shows plant tissues A and B, each of which shows three cells vertically connected, with signaling molecules depicted as shapes and arrows showing their movement

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Plant tissue A: Within the top cell, a triangular signaling molecule has arrows pointing to receptor proteins on the middle and bottom cells, both of which then point to their respective nuclei. Within the middle cell, a circular signaling molecule points to receptor proteins on the top and bottom cells, both of which then point to their respective nuclei. The arrows from the signaling molecules

indicate that they travel outside the plant tissue.

Plant tissue B: Within the top cell, a large circular signaling molecule points to the middle and bottom cell nuclei. Within the middle cell, a triangular signaling molecule points to the top and bottom nuclei. The arrows from the signaling molecules indicate that they travel only within the plant tissue.

Return to A diagram shows plant tissues A and B, each of which shows three cells vertically connected, with signaling molecules depicted as shapes and arrows showing their movement

Extended description for: Figure 21.2 Specific binding of ligand and receptor protein

Two receptor proteins span a cell membrane that separates cytosol from extracellular fluid. From the extracellular fluid, a circular, matching ligand binds to one of the

receptor proteins and a triangular, nonmatching ligand approaches but deflects off of the other receptor protein.

Return to Figure 21.2 Specific binding of ligand and receptor protein

Extended description for: Figure 21.3 Signal transduction of hydrophilic signaling molecules

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows a nucleated target cell with a Y-shaped receptor

spanning the cell membrane. The receptor stem embedded in the cell interior is labeled intracellular domain, and the part outside the cell is labeled, ligand-binding domain. A hydrophilic, polar signaling molecule binds to the ligand-binding domain, leading to an activated receptor that leads to a response.

Return to Figure 21.3 Signal transduction of hydrophilic signaling molecules

Extended description for: Figure 21.4 G protein-coupled receptor activation

The top illustration shows an activated receptor on the left along

the cell membrane, a G protein unit within the cell membrane containing G D P, and an inactive target protein along the cell membrane on the right. The middle illustration shows the G protein shifted left to bind to the activated receptor. Where the G protein originally contained G D P, it now contains G T P and produces G D P. The bottom illustration shows the G protein shifted to the right, binding to activate the target protein and producing a response.

Return to Figure 21.4 G protein-coupled receptor activation

Extended description for: Figure 21.5 Protein kinase activation by second messengers

The illustration shows an activated G protein-coupled receptor in a cell wall, and an active G protein bound to an activated adenylyl cyclase. Accompanying text reads, “Activated

adenylyl cyclase converts A T P to c A M P, which in turn activates kinases." The activated adenylyl cyclase converts A T P to c A M P which converts inactive kinase to active kinase. Accompanying text reads, "Activated kinases phosphorylate proteins in the cell, activating them."

Return to Figure 21.5 Protein kinase activation by second messengers

Extended description for: Figure 21.6 A signaling cascade

At the top, the illustration shows adrenaline in an activated receptor. Three arrows from the receptor point

to three activated adenylyl cyclase. Text reads: “Each activated receptor activates multiple G proteins, which in turn activate adenylyl cyclase enzymes.” This step is labeled amplification. Each of the activated adenylyl cyclase molecules has an active subunit of G protein. The A T P is converted into c A M P. Text reads: “Each adenylyl cyclase enzyme produces large amounts of c A M P, which activates many molecules of protein kinase.” This step is also labeled amplification. Six arrows from c A M P in turn point to six inactivated protein kinase molecules, which yields six activated protein kinases. Nine arrows from an activated protein kinase point to nine

protein targets with phosphate groups. This step is also labeled amplification. A T P is converted to A D P in this process. Text reads: “Each protein kinase enzyme phosphorylates and activates multiple protein targets.”

Return to Figure 21.6 A signaling cascade

Extended description for: Figure 21.7 Termination of G protein-coupled signaling

At the top, the illustration shows an activated receptor on the left, a beta gamma unit in the center, and an

activated adenylyl cyclase bound to a G protein on the right. Below the activated adenylyl cyclase, molecules of A T P are converted into c A M P, which activates protein kinase. An arrow from this illustration points down to another illustration in which the signaling cell from the receptor gets detached and the alpha unit is released from the adenyl cyclase. Text reads: “Adrenaline detaches from the receptor after a certain amount of time, inactivating the receptor so that it can no longer bind to and activate the G protein.” A phosphate group is released from the G protein. Text reads: “Within a very short time, an activated G protein deactivates itself by converting G T P to G D P.” An

arrow from c A M P points to A M P. Text reads: “Enzymes in the cytosol specifically degrade c A M P, which stops the phosphorylation and activation of target proteins.” Phosphatases remove phosphate groups from proteins, causing them to become inactive.

Return to Figure 21.7 Termination of G protein-coupled signaling

Extended description for: Figure 21.8 Receptor-protein kinase pathway

In the first stage, a signaling molecule approaches an inactive receptor, whose two halves have not yet come together. The second stage labeled activated receptor shows a receptor with the two halves of the receptor closed together around the signaling molecule. Between the second and third stages, a molecule of A T P loses

a phosphate group, which then binds to the part of the receptor inside the cytoplasm. This is the third stage. Six phosphate groups are bound to the receptor, which is now fully active. Text reads: “Each member of the receptor pair attaches phosphate groups to the other member.” In the final stage, cytoplasmic signaling proteins bind to each phosphate group on the receptor. Text reads: “The phosphate groups provide binding sites for intracellular signaling proteins.”

Return to Figure 21.8 Receptor-protein kinase pathway

Extended description for: An illustration shows an experiment that proves platelets, not plasma, are responsible for blood clotting

At the top, the illustration shows two

test tubes, one containing unclotted blood and the other containing clotted blood. Two Petri dishes with fibroblast are treated with serum from the clotted blood and plasma from the unclotted blood. The resulting number of fibroblasts in the plate with serum is greater than that in the plate with plasma.

Return to An illustration shows an experiment that proves platelets, not plasma, are responsible for blood clotting

Extended description for: A line graph shows fibroblasts divide more rapidly in serum as compared to plasma

The horizontal axis is labeled day and ranges from 1 to 6. The vertical axis is labeled number of cells times 10 to the power of 5 per dish and ranges

from 0 to 9. The curve labeled cultured with plasma rises slowly and steadily, passing through (1, 0.5), (2, 1), (3, 2), (4, 2.3), (5, 2.5), and (6, 2.7). The curve labeled cultured with serum rises rapidly before plateauing and then dropping slightly; it passes through (1, 3), (2, 7), (3, 8), (4, 8.5), (5, 8.9), and (6, 8). All data are approximate.

Return to A line graph shows fibroblasts divide more rapidly in serum as compared to plasma

Extended description for: A line graph shows fibroblasts divide more rapidly in platelet proteins as compared to plasma

The horizontal axis is labeled day and ranges from 1 to 6. The vertical axis is

labeled number of cells times 10 to the power of 5 per dish, and ranges from 0 to 6. A curve labeled cultured with plasma grows slowly and steadily before plateauing, passing through (1, 0.01), (2, 0.25), (3, 0.75), (4, 1.25), (5, 1.6), and (6, 1.75). A curve labeled cultured with platelet proteins grows more quickly, rising exponentially and passing through (1, 0.25), (2, 0.75), (3, 1.8), (4, 2.5), (5, 4.0), and (6, 5.75). All data are approximate.

Return to A line graph shows fibroblasts divide more rapidly in platelet proteins as compared to plasma

Extended description for: Figure 22.1 Agonists

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first part shows a signaling molecule binding to a receptor. The

activated receptor initializes a response in its corresponding cell.

The second part is identical to the first, but shows a food or drug molecule binding to the receptor instead.

Return to Figure 22.1 Agonists

Extended description for: Figure 22.3 Albuterol as an agonist of adrenaline receptors

The first part shows adrenaline binding to a receptor, which then activates a G protein, resulting in wider airways. The second part is

identical to the first, but shows albuterol binding to the receptor instead.

Return to Figure 22.3 Albuterol as an agonist of adrenaline receptors

Extended description for: Figure 22.4 Antagonists

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first part shows a signaling molecule binding to a receptor. The

activated receptor initializes a response in its corresponding cell.

The second part shows an antagonist binding to a receptor, which does not lead to a response.

Return to Figure 22.4 Antagonists

Extended description for: Figure 22.5 Caffeine, an antagonist of adenosine receptors

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first part shows adenosine binding to a receptor, which then activates a G protein, resulting in decreased alertness and increased sleepiness. The second part is

identical to the first, but shows caffeine binding to the receptor instead, which causes adenosine to be deflected, leaving the G protein inactive and resulting in increased alertness and decreased sleepiness.

Return to Figure 22.5 Caffeine, an antagonist of adenosine receptors

Extended description for: Figure 22.6 Adenosine and caffeine

The structural formula for caffeine shows a hexagon that shares a side with a pentagon. The top corner of the hexagon is double bonded to O, the top right and bottom right connect to the top left and bottom left corners of the pentagon, the bottom

corner shows N and is single bonded to C H subscript 3, the bottom left corner is double bonded to O, and the top left corner shows N single bonded to H subscript 3 C. The top left and bottom left corners of the pentagon are double bonded together. The top of the pentagon shows N single bonded to C H subscript 3. The top right and the bottom right corners of are double bonded together and the bottom right corner shows N.

The structural formula for adenosine shows a pentagon with its top left, bottom left, and bottom right corners single bonded to O H. The top shows O and the top left and top right corners are wedge bonded to the

bottom left and bottom right respectively, which are wedge bonded together. The top right corner of the pentagon is single bonded to the N depicted at the bottom corner of another pentagon that shares a side with a hexagon. The left and top corners of the second pentagon are double bonded together and the top corner shows N. The top right and bottom left corner connect to the top left and bottom left corners of the hexagon. The top and top right and bottom and bottom right corners are double bonded together. The bottom and top right corners show N. The top corner is single bonded to H subscript 2 N.

Return to Figure 22.6 Adenosine and caffeine

Extended description for: Figure 22.7 Altered proteins in cell communication

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A cell membrane separates extracellular fluid and cytoplasm. Receptor activation is depicted along a cell membrane. Receptor activation leads to signal transduction, during which the protein mutates by changing form, and leads to the

response. This finally leads to termination.

Return to Figure 22.7 Altered proteins in cell communication

Extended description for: Figure 23.1 Negative feedback

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A stimulus is detected by a sensor, which sends a signal to activate the effector. The effector in turn generates a response. The response blocks or reverses the effect of the stimulus on the sensor.

Return to Figure 23.1 Negative feedback

Extended description for: Figure 23.3 Negative feedback and insulin secretion

The stimulus or increase in blood glucose (right after a meal) is detected by the sensor, the pancreas, which is

located in the center of the torso, just below the ribcage. The pancreas produces insulin, which causes cells in the body to take up glucose, and muscle and liver cells to take up glucose and store it as glycogen. This uptake of glucose in response to insulin production is the effector. The response is a decrease in blood glucose, which is detected by the pancreas, so the feedback loop is stopped.

Return to Figure 23.3 Negative feedback and insulin secretion

Extended description for: Figure 23.4. Negative feedback and glucagon secretion

The stimulus or decrease in blood glucose (several hours after a meal) is detected by the sensor, the pancreas,

which is located in the center of the torso, just below the ribcage. The pancreas produces glucagon, which causes cells muscle and liver cells to break down glycogen to produce glucose. This breakdown of glycogen in response to glucagon production is the effector. The response is an increase in blood glucose, which is detected by the pancreas, so the feedback loop is stopped.

Return to Figure 23.4. Negative feedback and glucagon secretion

Extended description for: Figure 23.5 Positive feedback

A stimulus is detected by a sensor, which sends a signal to activate the effector. The effector in turn generates a response. The response enhances the effect of the stimulus on the sensor.

Return to Figure 23.5 Positive feedback

Extended description for: Figure 23.6 Positive feedback during labor and delivery

The illustration shows the cross-

section of a pregnant woman's abdomen with the uterus and birth canal labeled. The flowchart is as follows:

"Fetus causes birth canal to stretch," leads to "Stretching of birth canal stimulates nerves that send signals to the brain," leads to "Brain releases oxytocin," leads to "Oxytocin causes contractions of uterus, which pushes fetus toward the birth canal." Positive feedback from the final step leads back to, "Fetus causes birth canal to stretch."

Return to Figure 23.6 Positive feedback during labor and delivery

Extended description for: Figure 24.2 Steps of binary fission

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Stage 1: The circular bacterial D N A is attached to the cell membrane, red. The red point is labeled, Site of D N A attachment to membrane. Stage 2: The D N A is copied. Stage 3: Both D N A molecule are attached to the cell membrane. Stage 4: The cell elongates, separating the D N A attachment sites. Stage 5: New cell membrane and cell wall are synthesized at the midpoint. Stage 6: Two daughter cells are formed.

Return to Figure 24.2 Steps of binary fission

Extended description for: Figure 24.4 Interphase

The illustration consists of two loops. The first segment of the outer loop represents the M phase, mitosis and cytokinesis. The other segments on the outer loop in the clockwise

direction are: G 1 phase, S phase D N A synthesis, and G 2 phase. The inner loop, labeled interphase, cycles from the end of the M phase to the beginning of it. After M phase in the outer loop an arrow points outwards and reads, “G 0 phase, cells that are not actively dividing.”

Return to Figure 24.4 Interphase

Extended description for: Figure 24.6 Steps of mitosis

The stages of mitosis are as follows:

1. Prophase. An illustration shows a cell with chromatin fibers inside the

nuclear envelope. An arrow from the cell points to a cell in which the chromosomes condense. Centrosomes radiate microtubules and migrate to opposite poles.

2. Prometaphase. The nuclear envelope begins to break down and the chromosomes with sister chromatids begin to align themselves toward the center of the cell. Microtubules of the mitotic spindle attach to chromosomes.

3. Metaphase. The chromosomes are aligned completely in the center of the cell with the spindle pole at the end of each side.

4. Anaphase. Sister chromatids, which

become individual chromosomes when the centromere splits, separate and travel to opposite poles.

5. Telophase. The cell is about to divide into two and has two nucleuses. The nuclear envelope reforms and chromosomes decondense.

Return to Figure 24.6 Steps of mitosis

Extended description for: Figure 24.8 Cytokinesis in animal and plant cells

a. Animal cell cytokinesis

Top: Dr. Paul Andrews, University of Dundee/Science Source; bottom: Carolina Biological/Medical Images
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

b. Plant cell cytokinesis

Illustration A shows animal cell cytokinesis. A dividing cell, in the shape of two circles, shows two centrosomes and two reforming nucleuses. A contractile ring is present at the point of division. Illustration B shows the cytokinesis of plant cells. A dividing cell, in the shape of two squares, shows two reforming nucleuses and two centrosomes.

Return to Figure 24.8 Cytokinesis in animal and plant cells

Extended description for: Two illustrations labeled a and b shows two different cells during cell division

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Cell (a) is round and has a spindle pole on either end with lines that

extend from them towards chromosomes lined along the center of the cell. Cell (b) is oval-shaped with creases along the center of its membrane. There are two distinct ribbon structures contained on either side of the creases.

Return to Two illustrations labeled a and b shows two different cells during cell division

Extended description for: An infographic shows the process of cell division. An infographic shows the process of cell signaling

Cell division: Mitotic cell division is the process by which a single cell divides into two cells that, except for rare mutations, are genetically identical to the parent cell.

There are three illustrations. The first illustration shows a woman's back from which the skin is enlarged to show the epidermis and the dermis. The epidermis is enlarged, from which an epidermal cell is enlarged that undergoes the process of cell division.

The second illustration shows mitosis. 1. Prophase: Chromosomes condense. Centrosomes radiate microtubules and migrate to opposite poles. 2. Prometaphase: Spindles attach to kinetochores on chromosomes. 3. Metaphase: Chromosomes align in center of cell. 4. Anaphase: Sister chromatids, individual chromosomes when the

centromere splits, separate and travel to opposite poles. 5. Telophase and cytokinesis: Nuclear envelope re-forms, chromosomes condense, and the cytoplasm divides.

An arrow from the divided cell points to the epidermal cells. The third illustration shows a cell cycle that consists of two loops. The first segment of the outer loop represents the M phase, mitosis and cytokinesis. The other segments on the outer loop in the clockwise direction are: G 1 phase, S phase D N A synthesis, and G 2 phase, and the inner loop called interface. After M phase in the outer loop an arrow points outwards and reads, G 0 phase (cells that are not

actively dividing).

Cell signaling: Cells communicate with each other and respond to their environment using signaling molecules that bind to receptors, leading to responses inside the cell.

An illustration shows that signaling molecules from the blood vessel activates the receptors on the plasma membrane. The receptors undergo signal transduction and amplification which yields a response which is later terminated.

Return to An infographic shows the process of cell division. An infographic shows the process of cell signaling

Extended description for: Figure 25.2 Cyclins

The graph shows the fluctuation of the cyclin level in the embryo over the course of time. From first interphase to almost the end of mitosis, the cyclin levels peak from 0

to 49. They then drop back to 5 during the second interphase, peaking again when mitosis begins the second time at 50. When the cell has divided into 4, the cyclin levels drop down to around 13. A caption reads, “Level of cyclin increases and decreases, and then increases and decreases again as the embryo divides by mitosis.” Micrographs below the graph show a single cell at first interphase which then divides into two at second interface, then becomes four at the third interphase.

Return to Figure 25.2 Cyclins

Extended description for: Figure 25.3 Cyclins and cyclin-dependent kinases (CDKs)

In the first phase of the loop cyclin enters the cycle. At the end of this phase, the cyclin binds to another protein, called a cyclin-dependent kinase, or C D K, to become Cyclin-C D K complex. A caption reads: 1.

Cyclins bind to and activate cyclin-dependent kinases to control progression through the cell cycle.

2. Cyclin-C D K complexes phosphorylate target proteins that promote cell division. This phosphorylated target protein then exits the cycle. After this stage, the cyclin degrades and leaves the cycle, leaving the molecule of C D K to wait for another cyclin molecule to enter the cycle.

Return to Figure 25.3 Cyclins and cyclin-dependent kinases (CDKs)

Extended description for: Figure 25.4 Cell cycle checkpoints

The illustration consists of two loops. The first segment of the outer loop represents the M phase. The other

segments on the outer loop in the clockwise direction are: G 1 phase, S phase, and G 2 phase, and the inner loop is labeled interphase. A question mark is placed just before the end of G 1 phase with the caption: “D N A damage checkpoint, before entering S phase: Is D N A damaged?” Another question mark is placed just before the end of G 2 phase with the caption: “D N A replication checkpoint, at the end of G 2: Is all D N A replicated?” A question mark is placed just after M phase begins with the caption: “Spindle assembly checkpoint, before anaphase: Are all chromosomes attached to the spindle?”

Return to Figure 25.4 Cell cycle

checkpoints

Extended description for: Figure 25.5 Response to DNA damage

The first illustration shows a single strand of D N A and a small molecule of p 53 protein in the nucleus of the cell. Text reads, p 53 is a protein found in the nucleus.

The second illustration shows two points on the D N A strand

highlighted, indicating damage. Text reads, D N A damage activates protein kinases that phosphorylate p 53.

The third illustration shows three phosphorylated molecules of p 53. One phosphorylated molecule of p 53 is depicted on top of the D N A strand and turns on the gene. Text reads, Phosphorylated p 53 turns on genes that pause the cell cycle.

The fourth illustration shows the cell cycle. A negative feedback loop from the turned on gene blocks the cell cycle before S phase. Text reads, Pausing the cell cycle gives the cell time to repair the damaged D N A.

Return to Figure 25.5 Response to

DNA damage

Extended description for: Figure 25.6 Cancer progression

The first stage shows normal cells in which a cell is highlighted. A caption

reads: “Inactivation of p 53 allows a cell to divide in the presence of D N A damage.” The second stage shows a benign cancer with the caption: “A second mutation might accelerate cell division.” The third stage shows malignant cancer with the caption: “A third mutation might interfere with a cell cycle checkpoint.” The fourth stage shows metastatic cancer with the caption: “A fourth mutation might allow cells to migrate through the body.”

Return to Figure 25.6 Cancer progression

Extended description for: A graph shows five curves on a horizontal axis representing levels of different cyclins during G 0, G 1, S, G 2, M phases

The Cyclin D 1, D, and E curves shows a steady incline from G 0 to just before S where it peaks and steadily declines with D then E reaching slightly further ahead on the

horizontal axis. The Cyclin A curve begins at G1 with a shallow positive slope that steeply increases at S and peaks just before G 2 followed by a steep decline that meets the horizontal axis before M. The Cyclin B curve begins just before S with a shallow positive slope that steeply increases after G 2 and peaks just before M followed by a steep decline that meets the horizontal axis after M.

Return to A graph shows five curves on a horizontal axis representing levels of different cyclins during G 0, G 1, S, G 2, M phases

Extended description for: A flowchart shows a system of various hormones

Ovaries and testes release estrogens and androgens respectively which lead to pituitary and hypothalamus. The hypothalamus send G n R H to

pituitary and the pituitary sends L H and F S H to the testes and ovaries.

Return to A flowchart shows a system of various hormones

Extended description for: A flowchart depicts genotoxic stress

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In the none column is p 53. In the mild column, p 53 is bound to one phosphate group and leads to cell cycle arrest. In the severe column, p 53 is bound to two phosphate groups and leads to apoptosis.

Return to A flowchart depicts genotoxic stress

Extended description for: Figure 26.3 An overview of meiosis

The steps in meiosis 1 are as follows:

Prophase 1 (duplicated

chromosomes), Metaphase 1, Anaphase 1. Anaphase 1 leads to two separate cells in Telophase 1 and cytokinesis, the final stage of meiosis 1. Each cell undergoes meiosis 2 with the following steps: Prophase 2, Metaphase 2, Anaphase 2, and telophase 2 and cytokinesis (haploid), which shows four cells.

Return to Figure 26.3 An overview of meiosis

Extended description for: Figure 26.4 Prophase I

Stage 1: The first stage starts with a cell with two centrosomes, nuclear

envelope, and chromosomes. A caption reads: “Chromosomes first become visible as thin threads.” Stage 2: The centrosomes begin to move apart and microtubules are identified. A caption reads: “Homologous chromosomes continue to condense and undergo synapsis, gene for gene pairing.” Stage 3: The centrosomes move farther apart. A caption reads: “When synapsis is complete, each chromosome consists of two sister chromatids.” Stage 4: Chromosome chromatids cross over one another. A caption reads: “The chromosomes continue to shorten and thicken and the chiasmata between non-sister chromatids become apparent.” Stage 5: The illustration shows and caption

reads: “The nuclear envelope begins to break down.”

Return to Figure 26.4 Prophase I

Extended description for: Figure 26.5 Crossing over

The illustration shows a pair of homologous X-shaped chromosomes with paternal and maternal homolog. The sister and non-sister chromatids are identified. The non-sister chromatids cross over at the chiasmata in the bivalent which results in recombinant chromatids.

The recombinant chromatids now have parts of both paternal and maternal chromatids.

Return to Figure 26.5 Crossing over

Extended description for: Figure 26.6 Meiosis I

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The five stages are as follows:

Prophase 1: Chiasmata present. The illustration shows a cell with two centrosomes and a disappearing nuclear envelope. One of the bivalents has two chiasmata while the other has one.

Prometaphase 1: Spindles attach to kinetochores on chromosomes.

Metaphase 1: Homologous pairs line up in center of cell, with bivalents oriented randomly with respect to each other.

Anaphase 1: Homologous chromosomes separate, but sister chromatids do not separate. The illustration shows the chromosomes moving toward the centromeres.

Telophase 1 and cytokinesis:
Daughter cells are ready to move into prophase 2. The illustration shows the two cells with reforming nuclear envelope having two pairs of different recombinant chromosomes each.

Return to Figure 26.6 Meiosis I

Extended description for: Figure 26.7 Meiosis II

The stages are as follows:

Prophase 2: The nuclear envelope

breaks down and the chromosomes condense. The illustration shows the two daughter cells from meiosis 1.

Prometaphase 2: Spindles attach to kinetochores on chromosomes.

Metaphase 2: Chromosomes align in center of the cell.

Anaphase 2: Sister chromatids separate.

Telophase 2 and cytokinesis: The nuclear envelope reforms and the cytoplasm divides.

Four cells are formed that have two chromatids each, which can either be homologous chromatids,

recombinant chromatids, or both.

Return to Figure 26.7 Meiosis II

Extended description for: Figure 26.8 Comparing mitosis and meiosis

The illustration shows a diploid parent cell which undergoes meiosis

and mitosis. In mitosis the cell undergoes the following four stages: Prophase (duplicated chromosomes), Metaphase, Anaphase, and Telophase and cytokinesis (diploid). The resultant two cells contain four homologous chromatids, each.

In meiosis there are two stages, meiosis 1 and Meiosis 2. In meiosis 1, the diploid parent cell undergoes the following four stages: Prophase 1 (duplicated chromosomes), Metaphase 1, Anaphase 1, and Telophase 1 and cytokinesis. The resultant two cells contain two pairs of recombinant chromosomes, each. These two cells undergo meiosis 2 and the four stages are: Prophase 2,

Metaphase 2, Anaphase 2, and Telophase 2 and cytokinesis (haploid). The resultant four cells have two chromatids, each, which can either be homologous chromatids, recombinant chromatids, or both.

In prophase of both the cell division process, the envelope breaks down and the chromosomes condense. In metaphase of both the cell division process, chromosomes align in center of the cell. In anaphase of both the cell division process, the chromatids or chromosomes separate. In telophase and cytokinesis of both the cell division process, new cells, haploid or diploid, are formed.

Return to Figure 26.8 Comparing mitosis and meiosis

Extended description for: Figure 26.9 Unequal allocation of cytoplasm during meiosis in female and male animals

The first four stages of cytoplasmic division look the same in the

flowchart for both sexes. In the first stage, four individual chromatids are inside the nuclear envelope of a cell. The second stage is where D N A replication takes place, and bivalents are formed by the chromosomes in the cells of both sexes. Next, the first meiotic division occurs, where recombinant chromosomes are separated. Two cells are formed for each sex with two pairs of recombinant chromosomes, each. The second meiotic division then occurs which results in four cells that have two chromatids each, which can either be homologous chromatids, recombinant chromatids, or both. In males, the second meiotic division results in four cells of fairly equal

size, each of which will form a sperm cell. In females, most of the cytoplasm is retained in a larger cell which becomes an oocyte. The smaller cells with less amount of cytoplasm become polar bodies.

Extended description for: An illustration shows various groupings of chromosomes with linear chromatids centered on a centromere

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The parental cell (2 n equals 4) depicted at the top, contains two pairs of chromosomes, one pair dark and the other light, each with a short and long chromosome. Four rows, a through d, show four different

combinations of the aforementioned chromosomes.

Row a: cells 1 and 3 show long dark and long white, cells 2 and 4 show short white and short dark.

Row b: cell 1 shows long white, cell 2 shows short dark, cell 3 shows short white, cell 4 shows long dark.

Row c: cell 1 shows long dark short white, cell 2 shows short dark long white, cell 3 shows the white pair, and cell 4 shows the dark pair.

Row d: each cell shows all chromosomes but in different arrangements as follows: cell 1 shows long dark, short white, long white,

short dark; cell 2 shows short dark, long white, short white, long dark; cell 3 shows short white, short dark, long white, long dark; cell 4 shows long white, short white, long dark, short dark.

Extended description for: Figure 27.2 Pea plant phenotypes

The data from the chart are as follows: Color of seeds: Yellow and Green. Shape of seeds: Round and Wrinkled. Color of pod: Green and Yellow. Shape of pod: Smooth and

Indented. Color of flower: Purple and White.

Return to Figure 27.2 Pea plant phenotypes

Extended description for: Figure 27.3 Crossing different P1mathml alt text varieties to create the F1mathml alt text generation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows the first two plants of the P 1, or parental generation. Each plant is grown from a purebred strain, one with yellow seeds, and one with green. Purebred strains that are crossed constitute the P 1 or parental generation. The cross results in a plant with yellow seeds.

The trait that appears in the F 1 generation (in this case yellow seeds) is dominant, and the other trait (green seeds) is recessive.

Return to Figure 27.3 Crossing different P1mathml alt text varieties to create the F1mathml alt text generation

Extended description for: Figure 27.4 Crossing F1mathml alt text hybrids to produce the F2mathml alt text generation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The parent generation shows two plants, one with yellow peas and one with green peas. F 1 generation shows only yellow peas. A caption reads: “Seeds from F 1 plants produced from

a cross of purebred yellow-seed and green-seed plants are yellow because yellow is dominant and green is recessive." F 2 generation shows mostly yellow peas but some green peas as well. A caption reads: "In the F 2 generation, the ratio of dominant to recessive phenotypes for the whole plant is 3 to 1."

Return to Figure 27.4 Crossing F1mathml alt text hybrids to produce the F2mathml alt text generation

Extended description for: Figure 27.5 Homozygous and heterozygous allele combinations

The four possible allele combinations are as follows: The first pair, labeled "Homozygous capital A capital A," both have allele 1. The second and

third pair, labeled “Heterozygous capital A small A, small A capital A,” show allele 1 and 2, and 2 and 1 respectively. The fourth pair, labeled “Homozygous small A small A,” both have allele 2.

Return to Figure 27.5 Homozygous and heterozygous allele combinations

Extended description for: Figure 27.6 How the law of segregation creates the F1mathml alt text and F2mathml alt text generations

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows the P 1 generation pea seeds. One is yellow (capital A capital A) and other is green (small A small A). Text reads, Purebred plants are homozygous, and each produces one type of gamete. The cross results in yellow pea seed in F 1 generation with capital A small A genotype. Next, the F 1 progeny are self-fertilized. The F 2 generation shows a 2 by 2 Punnett Square with similar column and row headers: capital A and small A. The row entries are as follows:

Row 1: Capital A capital A yellow seed; Capital A small A yellow seed.

Row 2: Capital A small A yellow seed;

Small A small A green seed.

Text reads, Expected ratio of capital A capital A to capital A small A to small A small A genotypes is 1 to 2 to 1. Expected ratio of dominant to recessive phenotypes is 3 to 1.

Return to Figure 27.6 How the law of segregation creates the F1mathml alt text and F2mathml alt text generations

Extended description for: Figure 27.7 Incomplete dominance in snapdragons

The illustration shows the P 1 generation with a red flower (C superscript R, C superscript R) and a white flower (C superscript W, C superscript W). The cross results in pink flowers in F 1 generation with C

superscript R, C superscript W genotype. Text reads, The phenotype of the heterozygous C superscript R, C superscript W plant is intermediate, an example of incomplete dominance.

Next, the F 1 progeny are self-fertilized. The F 2 generation shows a 2 by 2 Punnett Square with similar column and row headers: 1 by 2 C superscript R and 1 by 2 C superscript W. The row entries are as follows:

Row 1: 1 by 4, C superscript R, C superscript R, red flowers; and 1 by 4, C superscript R, C superscript W, pink flowers.

Row 2: 1 by 4, C superscript R, C

superscript W, pink flowers; and 1 by 4, C superscript W, C superscript W, white flowers.

Text reads, The result of segregation can be observed directly, because the ratio of red to pink to white phenotypes is 1 to 2 to 1, which reflects the ratio of C superscript R, C superscript R to C superscript R, C superscript W to C superscript W, C superscript W genotypes.

Return to Figure 27.7 Incomplete dominance in snapdragons

Extended description for: Figure 27.8 Crossing pea plants that differ in two traits (a dihybrid cross)

Morris, et al., *Biology for the AP® Course*, 1e © 2022 BFW High School Publishers

The parent generation shows two plants grown from purebred strain

with yellow and wrinkled seeds (capital A capital A, small B small B) or green and round seeds (small A small A, capital B capital B). F 1 generation shows only yellow peas with genotype capital A small A, capital B small B. A caption reads: “Because of dominance, the seeds in the F 1 generation are yellow and round.” The F 2 generation shows mostly yellow peas but some green peas as well. A caption reads: “The expected ratio of the four types of seeds is 9 yellow, round; 3 green, round; 3 yellow, wrinkled; and 1 green, wrinkled.”

Return to Figure 27.8 Crossing pea plants that differ in two traits (a

dihybrid cross)

Extended description for: Figure 27.9 Punnett square for two independently assorting traits

The Punnett square shows the result

of a cross between four ovule gametes and four pollen gametes. The gametes representing the column and row headers are: 1 by 4 capital A capital B; 1 by 4 capital A small B; 1 by 4 small A capital B; and 1 by 4 small A small B. The row entries are as follows:

Row 1: 1 by 16 capital A capital A, capital B capital B yellow, round seeds; 1 by 16 capital A capital A, capital B small B yellow, round seeds; 1 by 16 capital A small A, capital B capital B yellow, round seeds; and 1 by 16 capital A small A, capital B small B yellow, round seeds.

Row 2: 1 by 16 capital A capital A, capital B small B yellow, round seeds;

1 by 16 capital A capital A, small B small B yellow, wrinkled seeds; 1 by 16 capital A small A, capital B small B yellow, round seeds; and 1 by 16 capital A small A, small B small B yellow, wrinkled seeds.

Row 3: 1 by 16 capital A small A, capital B capital B yellow, round seeds; 1 by 16 capital A small A, capital B small B yellow, round seeds; 1 by 16 small A small A, capital B capital B green, round seeds; and 1 by 16 small A small A, capital B small B green, round seeds.

Row 4: 1 by 16 capital A small A, capital B small B yellow, round seeds; 1 by 16 capital A small A, small B

small B yellow, wrinkled seeds; 1 by 16 small A small A, capital B small B green, round seeds; and 1 by 16 small A small A, small B small B green, wrinkled seeds.

Return to Figure 27.9 Punnett square for two independently assorting traits

Extended description for: An illustration shows two independent assortments of genes in different chromosomes in two daughter cells during meiosis

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first illustration shows two cells undergoing anaphase 1 of meiosis. The spindles have pulled two pairs of chromosomes apart in each one. In the first cell, the chromosomes on the top contain two capital A alleles and two capital B alleles. The chromosomes on the bottom contain two small A alleles, and the last one two small B alleles. In the second cell, the chromosomes on the top contain two capital A alleles and two small B alleles. The chromosomes on the bottom contain two small A alleles, and the last one two capital B alleles. Each cell ends up with four gametes after meiosis 2. For the first cell, there are two cells with both capital alleles and two cells with both small alleles.

For the second cell, two cells each contain a copy of capital A and small B, and two contain small A and capital B.

Return to An illustration shows two independent assortments of genes in different chromosomes in two daughter cells during meiosis

Extended description for: Figure 27.11 A pedigree

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A family tree shows the use of different shapes to represent people, offspring, and mating. There are four generations used in the illustration. Generation one contains one female parent and one male parent.

Generation 2 consists of three male offspring and four female offspring. The progeny of two of the female offspring and one of the males make up Generation 3, resulting in four female progeny and three males in total. There is one set of female identical twins and one set of non-identical twins (a male and a female) in this generation. The male progeny of a male and a female cousin in this generation is the only member of Generation 4.

The symbols generally used in pedigree charts are as follows: A circle represents a female. A square represents a male. If the shape is not colored, it means that that person is

not affected by a particular trait. If the shape is colored, it means the person is affected. A horizontal line between individuals represents mating. Vertical lines lead to the progeny of individuals. These progeny are arranged horizontally, from left to right in order of birth on a subsequent horizontal line. A double line means mating between relatives. Non-identical twins are represented by diagonal lines. Identical twins are represented by diagonal lines with a small horizontal line between them forming a triangle shape. In this case, the chart reveals that three people are affected: a male and a female in Generation 2, and the male in Generation 4.

Return to Figure 27.11 A pedigree

Extended description for: Figure 27.12 A pedigree of the rare dominant gene for the brachydactyly phenotype

Photo: Stefan Mundlos, Institute for Medical Genetics, Charité, Berlin, Germany
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The family reads as follows. Generation one shows one female parent and one male parent, and the female symbol is colored. A caption reads, For a rare dominant trait, most matings that produce affected

offspring have only one affected parent. In the second generation, four (one male and three females) out of eleven offspring are affected by this trait, one of whom passes it on to his two males and five females. In pairings in which one parent is affected by this allele, it is normal for close to half of their offspring to also be affected. In the third generation, three males and three females are affected. In the fourth generation, seven males and nine females are affected. In each subsequent generation, affected individuals appear, and they are equally likely to be male or female.

Return to Figure 27.12 A pedigree of

the rare dominant gene for the brachydactyly phenotype

Extended description for: Figure 27.13 A pedigree of the rare recessive gene for blue eyes

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Neither the first nor the second generation expresses this rare recessive trait, as it can skip one or more generations. In generation 3, the trait shows up in one female and

one male. Generation 4 shows five affected individuals. Three females and two males have the trait, showing that it is equally likely for a male or female to carry it. Four of these individuals are a result from mating between relatives. The other affected individual has parents who are not affected.

Return to Figure 27.13 A pedigree of the rare recessive gene for blue eyes

Extended description for: A family tree shows three generations of wall-eyed, brown eyed, and unknown individuals

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In the first generation are two pairings. The first pairing is of two wall-eye individuals and the second of a brown eye male and unknown female 1. The first pairing produces unknown male 2, a brown eye female,

and wall-eye male. The second pairing produces a brown eye female and wall-eye male. The wall-eye male progeny of the first pairing reproduces with the brown eye female progeny of the second pairing, producing a wall-eye male, unknown female 3, and two brown eye females. The wall-eye male progeny of the second first generation pairing reproduces with a brown eye female and produces unknown male 4 and a wall-eye female.

Return to A family tree shows three generations of wall-eyed, brown eyed, and unknown individuals

Extended description for: Figure 28.1 Epistasis in chickens

Left: Andrea Mangoni/Shutterstock; right: Dr. Don Monke
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The chicken on the right is smaller and has patches of a darker color in its white feathers. The chicken on the right is larger and has all white

feathers. The first flowchart reads: Gene 1 (capital C small c or capital C capital C) leads to dark pigment. Next, addition of Gene 2 (small i small i) results in dark pigment while addition of Gene 2 (capital I capital I or capital I small i) results in no pigmentation.

The second flowchart reads: Gene 1 (small c small c) leads to no pigment. Next, addition of Gene 2 (capital I capital I, capital I small i, or small i small i) results in no pigmentation.

Return to Figure 28.1 Epistasis in chickens

Extended description for: Figure 28.2 Crossing purebred chickens to observe epistasis

Morris, et al., *Biology: For the AP® Course*, 1e. © 2022 BFW High School Publishers

In the P subscript 1 generation, the illustration shows a white chicken

with genotype capital C capital C capital I capital I. Corresponding text reads, The White Leghorn is white because the inhibitor allele capital I blocks expression of the pigment allele capital C. Another white chicken in P subscript 1 generation has the genotype small c small c small i small i. Corresponding text reads, The White Wyandotte is white because the pigment allele small c does not produce pigment. The cross in the P subscript 1 generation yields a White Leghorn and a White Wyandotte with capital C small c capital I small i genotype in the F 1 generation. A cross between the White Leghorn and the White Wyandotte from the F subscript 1

generation produces a 4 by 4 Punnett square. The column headers are similar to the row headers and are as follows: 1 by 4 capital C capital I; 1 by 4 capital C small i; 1 by 4 small c capital I; and 1 by 4 small c small i. The row entries are as follows:

Row 1: capital C capital C capital I capital I, white; capital C capital C capital I small i, white; capital C small c capital I capital I, white; and capital C small c capital I small i, white.

Row 2: capital C capital C capital I small i, white; capital C capital C small i small i, brown; capital C small c capital I small i, white; and capital C small C small i small i, brown.

Row 3: capital C small c capital I capital I, white; capital C small c capital I small i, white; small c small c capital I capital I, white; and small c small c capital I small i, white.

Row 4: capital C small c capital I small i, white; capital C small c small i small i, brown; small c small c capital I small i, white; and small c small c small i small i, white.

Corresponding text reads: Alleles, capital C equals pigment; small c equals no pigment; capital I equals inhibitor; and small i equals no inhibitor.

Text below the Punnett square reads, Genotypes of the form capital C dash

small i small i have colored feathers, whereas all other genotypes have white feathers. The result is an F subscript 2 ratio of white to colored of 13 to 3, which is a modified form of the expected 9 to 3 to 3 to 1.

Return to Figure 28.2 Crossing purebred chickens to observe epistasis

Extended description for: Figure 28.4 X and Y chromosomes in humans

The illustration shows a large rod-shaped X chromosome and a smaller rod-shaped Y chromosome with both their ends highlighted.

Corresponding text reads: Almost

none of the genes in the X chromosome have counterparts in the Y chromosome. The tip of the arms of the X and Y chromosomes share a small region of homology (red). The micrograph shows a large X-shaped X chromosome and a smaller X-shaped Y chromosome.

Return to Figure 28.4 X and Y chromosomes in humans

Extended description for: Figure 28.5 A Punnett square of sex chromosomes

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Meiosis in a female results in X-bearing eggs only. Two X chromosomes results in two 1 by 2 X chromosomes. The column headers represent eggs and are labeled X and X. Meiosis in a male results in a 1 to 1 ratio of X-bearing and Y-bearing sperm. Two X and Y chromosomes result in 1 by 2 X and 1 by 2 Y chromosomes. The row headers represent sperm and are labeled X and Y. The row entries are as follows:

Row 1: X X female, and X X female.

Row 2: X Y male, and X Y male.

Text reads, Random fertilization results in an expected ratio of X X (female) and X Y (male) progeny.

Return to Figure 28.5 A Punnett square of sex chromosomes

Extended description for: Figure 28.6 Fruit fly crosses with an X-linked trait

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In the parental generation, a red-eyed female fly crosses with a white-eyed male fly. The F subscript 1 generation results in red-eyed flies. Text reads: All of the F subscript 1 progeny have red eyes. Next, crossing a red-eyed female fly with a red-eyed male fly in the F subscript 1 generation leads to a red-eyed female fly, a red-eyed male fly, and a white-eyed male fly in the F subscript 2 generation. Text reads: White eyes reappear in the F subscript 2 generation, but only in males. All of the females have red eyes, and among the males, the ratio of red is to white eyes is 1 to 1.

Return to Figure 28.6 Fruit fly crosses with an X-linked trait

Extended description for: Figure 28.7 A Punnett square for X-linked traits

Morris, et al., Biology for the AP® Course, 1e, © 2022 BFW High School Publishers

(a) The Punnett square shows a cross between a homozygous female and an affected male. Text reads: Most genes in the X chromosome have no counterparts in the Y chromosome.

Therefore, a recessive mutation, such as white eyes, in an X-linked gene is expressed in males. The result is two heterozygous females and two unaffected males. Text reads: A male with an X-linked recessive trait, such as white eyes, will have heterozygous (carrier) daughters and unaffected sons.

(b) The Punnett square shows a cross between a heterozygous carrier female and a normal male. The result is a heterozygous female, a homozygous female, an affected male (white eyes), and an unaffected male. Text reads: Among progeny from a heterozygous carrier female, half of the daughters are expected to be

heterozygous carriers and half the sons are expected to be affected.

Return to Figure 28.7 A Punnett square for X-linked traits

Extended description for: Figure 28.9 A pedigree for human colorblindness, an X-linked trait

At the top left is a symbol key showing white square equals unaffected male (X superscript plus, Y), white circle equals unaffected female (X superscript plus, X superscript plus or

X superscript plus, X superscript C), and red square equals affected male (X superscript C, Y). The first generation shows a red square and a white circle. A label reads: For a rare X-linked recessive trait, most affected individuals are male. The second generation has no red squares. The square at the left of this generation has a label that reads, The offspring of an affected male are usually not affected. A circle at the right side of this generation has a label that reads, The heterozygous daughters of affected males can have affected sons. In the third generations, a daughter produces 4 affected sons, one unaffected son, and 4 unaffected daughters. A label on one daughter

reads: The sisters of an affected male can have affected sons. An affected son produces two unaffected daughters in the fourth generation, and an unaffected daughter produces two affected sons in the fourth generation.

Another daughter from the second generation produces two affected sons, two unaffected sons, and one unaffected daughter. An unaffected son produces three unaffected daughters in the fourth generation, and an unaffected daughter produces an affected son in the fourth generation.

Return to Figure 28.9 A pedigree for

human colorblindness, an X-linked trait

Extended description for: Figure 28.10 A pedigree for a Y-linked gene

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first generation shows an unaffected female and an affected male. Text reads, Only males exhibit the trait. The second generation shows three sons exhibiting the trait and a daughter that does not exhibit the trait. Text at this level reads: Females do not inherit or transmit the

trait. Next, an affected male from the second generation mates with an unaffected female to produce two affected sons and four unaffected daughters in the third generation. Text reads, All sons of males with the trait also show the trait. Another affected male from the second generation mates with an unaffected female to produce four affected sons and two unaffected daughters in the third generation. An unaffected female from the second generation mates with an unaffected male to produce two unaffected sons and two unaffected daughters in the third generation.

Return to Figure 28.10 A pedigree for

a Y-linked gene

Extended description for: Figure 28.11 Crossing over between linked genes

(a) The schematic shows two chromosomes with genes capital A and capital B in one chromosome and small A and small B in another. Text reads: Crossing over in prophase 1 of meiosis is a physical exchange of chromosome parts. After the crossing

over, capital A of one arm joins with small B in one chromosome and small A of one arm joins with capital B in another chromosome. Text reads: Crossing over between two genes results in two recombinant and two nonrecombinant chromosomes. The result is a nonrecombinant chromosome for capital A and capital B genes, two recombinant chromosomes for A and B genes, and a nonrecombinant for small A and small B genes. Text reads: The overall frequency of recombinant chromosomes is a measure of the genetic distance between the two genes.

(b) The schematic shows two

chromosomes with genes capital A and capital B in one chromosome and small A and small B in another. Text reads: Crossing over does not always take place between genes of interest. After the crossing over, the small A and small B arm joins the first chromosome and the capital A and capital B arm joins the second chromosome. The result is four nonrecombinant chromosomes for A and B genes. Text reads: If crossing over occurs, but not between two genes, the result is four nonrecombinant chromosomes.

Return to Figure 28.11 Crossing over between linked genes

Extended description for: Figure 28.12 Linked genes in fruit flies

Morris, et al. *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In the parental generation, a red-eyed, crossveined female fly (w plus c

v plus over w plus c v plus) crosses with a white-eyed, crossveinless male fly (w minus c v minus over capital Y). Text reads, Female is homozygous for both nonmutant alleles (for red eyes and normal wing veins). Male has both mutant alleles (for white eyes and crossveinless wings). The F subscript 1 generation results in a red-eyed, crossveined female fly (w plus c v plus over w minus c v minus) and a red-eyed, crossveined male fly (w plus c v plus over capital Y). Text reads: Progeny females are heterozygous for both mutant alleles.

Next, a cross between the F subscript 1 generation leads to the F subscript 2 generation (only males shown). The

result is 357 red-eyed, crossveined male flies (w plus c v plus over capital Y); 341 white-eyed, crossveinless male flies (w minus c v minus over capital Y); 52 red-eyed, crossveinless male flies (w plus c v minus over capital Y); and 45 white-eyed, crossveined male flies (w minus c v plus over capital Y).

The 357 red-eyed, crossveined male flies and 341 white-eyed, crossveinless male flies are labeled, With independent assortment, a ratio of 1 to 1 to 1 to 1 is expected. With linkage, the progeny show an excess of the original parental types, as indicated by the number of fruit flies counted.

Return to Figure 28.12 Linked genes in fruit flies

Extended description for: Figure 28.13 The organelles of egg and sperm cells

On the left is a diagram of the mammalian egg cell. It is circular and shows a circle inside to represent the nucleus with lines to represent the chromatin within it. The cell body contains rough endoplasmic reticulum as well as smooth endoplasmic reticulum with their

locations around the outside of the nucleus. At the right within the cell is a blob labeled centrosome. Below this are three circles labeled lysosome. At the bottom left of this cell is an egg shaped vacuole, and at the right near the bottom are two bean shaped mitochondria.

At the right is a diagram of a sperm. This cell has a small egg shaped head at left, with a tail coming out to the right. Labeled in the left side of the head is an oval labeled acrosome. The center of the head shows a nucleus with chromatin. Behind the head is a small blob labeled centriole. Behind this, and into the tail, is a section of bean shaped mitochondria. The tail

has a long wave-like line through it to the end.

Extended description for: A pedigree chart shows inheritance of an unknown disorder across three generations

Unaffected male
Unaffected female
Affected male
Affected female

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The first generation shows two couples. The first couple has an unaffected female and an unaffected male while the second couple has an affected male and an unaffected female. In the second generation, the first couple produces an unaffected daughter and an affected son, and the second couple produces two unaffected daughters.

The unaffected daughter from couple one mates with an unaffected male to produce an unaffected son and an unaffected daughter in the third generation. The affected son from couple one mates with an unaffected daughter from couple two to produce an affected son in the third

generation. The unaffected daughter from couple two mates with an unaffected male to produce an affected son and two unaffected daughters in the third generation.

Extended description for: An illustration and an equation show the probability of obtaining a specific sequence of seeds

$$\frac{3}{4} \times \frac{1}{4} \times \frac{3}{4} \times \frac{1}{4} \times \frac{3}{4} = \frac{27}{1024}$$

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration of 5 seeds shows the following sequence of shapes: smooth, wrinkled, smooth, wrinkled, and smooth. Below, the equation shows the fraction obtaining the corresponding seed shape as follows: 3 by 4 multiplied by 1 by 4 multiplied

by 3 by 4 multiplied by 1 by 4 multiplied by 3 by 4 equals 27 by 1024.

Return to An illustration and an equation show the probability of obtaining a specific sequence of seeds

Extended description for: Figure 29.2 Phenotypic plasticity in gray treefrog tadpoles

The photo (a) shows two tadpoles raised with and without predators. The one at the top is very pale, and has a short tail and the one at the bottom has a long colorful tail.

The graph (b) plots tadpole activity

with and without predators. The vertical axis represents activity (percent of time moving) and ranges from 20 to 50. The data point for the tadpole without predators lies at 42 percent and one-third of the horizontal axis. The data point for the tadpole with predators lies at 25 percent and two-third of the horizontal axis. Both points have vertical error bars ranging approximately 3 percent on both sides. All data are approximate.

The graph (b) plots tail depth with and without predators. The vertical axis represents relative tail depth and ranges from negative 0.03 (shallow) to 0.03 (deep). The data point for tail

depth without predators lies slightly above negative 0.01 and one-third of the horizontal axis. The data point for tail depth with predators lies slightly above 0.03 and two-third of the horizontal axis. Both points have vertical error bars ranging approximately 0.005 on both sides. All data are approximate.

Extended description for: A bar graph plots wood frog relative growth under different conditions

The horizontal axis plots bars for no predator slash no competition, no predator slash competition, predator-induced slash no competition, and predator-induced slash competition. The vertical axis represents wood frog

relative growth (final mass divided by initial mass) and ranges from 0.8 to 1.4. The approximate data are as follows: No predator slash no competition, 1.22; No predator slash competition, 1.38; Predator-induced slash no competition, 1.17; and Predator-induced slash competition, 1.28. All bars show vertical error bars. Data are means plus/minus 1 S E.

Return to A bar graph plots wood frog relative growth under different conditions

Extended description for: Figure 29.6 Different corn strains in a range of nitrogen environments

The horizontal axis represents nitrogen enrichment (kilograms per hectare) and ranges from 0 to 120 in increments of 20. The vertical axis represents grain yield (kilograms per

hectare) and ranges from 0 to 5000 in increments of 1000. The data points for corn strain 1 are at (1, 3100), (30, 3400), (60, 3500), (90, 3900), and (120, 3800). The data points for corn strain 2 are at (1, 1800), (30, 2300), (60, 3650), (90, 4050), and (120, 4900). Lines have been fitted to the data. The line for strain 2 begins below strain 1 and crosses it at (68, 3500). All data are approximate.

Extended description for: Figure 29.8 Phenotypic trade-offs in goldfish swimming when raised at cold and warm temperature

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The horizontal axis represents test temperature (in degree Celsius) and ranges from 0 to 40 in increments of 10. The vertical axis represents swimming speed (centimeters per second) and ranges from 0 to 60. A curve representing goldfish raised at 5 degrees Celsius starts from (0, 10), increases to (15, 35), and drops down to end at (24, 26). A curve representing goldfish raised at 25 degrees Celsius starts from (14, 28), increases to (29, 52), and drops down to end at (34, 36). All data are approximate.

Return to Figure 29.8 Phenotypic trade-offs in goldfish swimming when raised at cold and warm temperature

Extended description for: Four graphs plot (a) year versus mass at weaning, (b) mass at weaning versus year, (c) mass at weaning versus year, and (d) breed versus mass at weaning

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

(a) The horizontal axis represents mass at weaning (kilograms) and ranges from 40 to 45. The vertical axis represents year and is labeled 1989 and 1990. The approximate data points are Spel (41, 1989); Spel (43, 1990); N W S (44, 1989); and N W S (45, 1990).

(b) The horizontal axis represents year and is labeled 1989 and 1990. The vertical axis represents mass at weaning (kilograms) and ranges from 40 to 45. The approximate data points are Spel (slightly after 1989, 44.6); Spel (slightly before 1990, 44); N W S (slightly after 1989, 43); and N W S (slightly before 1990, 40.8).

(c) The horizontal axis represents year and is labeled 1989 and 1990. The vertical axis represents mass at weaning (kilograms) and ranges from 40 to 45. The approximate data points are Spel (1989, 40.6); Spel (slightly before 1990, 42.4); N W S (1989, 43.2); and N W S (slightly before 1990, 43.9).

(d) The horizontal axis represents mass at weaning (kilograms) and ranges from 40 to 45. The vertical axis represents breed and is labeled N W S and Spel. The approximate data points are 1989 (41, Spel); 1990 (43, Spel); 1989 (44, N W S); and 1990 (45, N W S).

Return to Four graphs plot (a) year

versus mass at weaning, (b) mass at weaning versus year, (c) mass at weaning versus year, and (d) breed versus mass at weaning

Extended description for: A double bar graph plots indole produced versus leaf area consumed for two genotypes

The horizontal axis represents leaf area consumed (percent) and is labeled 10, 30, and 50. The vertical

axis represents indole produced (nanograms) and ranges from 0 to 30, in increments of 5. The approximate data are as follows:

10 percent: Genotype A, 9.5 nanograms; and Genotype B, 10.2 nanograms.

30 percent: Genotype A, 11. 5 nanograms; and Genotype B, 11 nanograms.

50 percent: Genotype A, 22 nanograms; and Genotype B, 27.5 nanograms.

All bars have vertical error bars at the top.

Return to A double bar graph plots indole produced versus leaf area consumed for two genotypes

Extended description for: Visual Synthesis 5.1 THE COMBINED EFFECTS OF GENES AND THE ENVIRONMENT IN DETERMINING PHENOTYPES

B R C A 1 Genetics: The B R C A 1 gene in chromosome 17 encodes a protein that repairs double-strand breaks in D

N A that result from D N A replication or environmental agents. The B R C A 1 gene is present in all cells, but is expressed, or turned on, in rapidly dividing cells, including breast and ovarian cells. If B R C A 1 does not function properly due to a mutation, damaged D N A in the cell is not repaired, which in turn increases the risk for certain kinds of cancers, particularly breast and ovarian cancers in women.

An illustration shows a woman with breast tissues enlarged to shows a tumor, which is further enlarged to show a mutant cell. The nucleus of the mutant cell is enlarged to show a pair of chromosome 17 with a mutant

B R C A 1 allele on each chromosome. A healthy cell from the woman's arm is enlarged to show a pair of chromosome 17 with a normal allele on one chromosome and a mutant B R C A 1 on other.

A pedigree chart begins with step 1 labeled Genetic variation. The text reads: Everyone carries two copies of the B R C A 1 gene on chromosomes 17. Some individuals have an allele of the gene that increases the risk of breast and ovarian cancer. In some populations, such as Ashkenazi Jews, the frequency of specific mutations in the gene is high. Below this the chart shows a red circle labeled RUTH (red indicates affected person) linked to a

white square labeled ISAAC. Both have a normal allele and a mutant allele. The infographic then jumps to step 4, labeled Mutation. The text reads: This individual inherits one mutation in the B R C A 1 and is heterozygous. In one cell or a few of her cells, a new mutation is acquired in the normal B R C A 1 gene, and these cells go on to be cancerous. Genotype and phenotype: For a woman with a mutation in B R C A 1, the risk of breast cancer by age 40 is 37 percent; by age 55, 66 percent; and by age 80, 85 percent. The pedigree next to this text shows the offspring of Isaac and Ruth: a red circle labeled Susan (a normal and a mutant allele) and a white circle labeled Sarah (both

normal alleles), who is linked to a male labeled Ben (a normal and a mutant allele).

Testing and Ethical Issues: D N A testing can be used to determine whether or not a person carries an allele of a gene that increases the risk of a disease, but it also raises questions and ethical issues. In 2008, the Genetic Information Nondiscrimination Act (G I N A) was passed to protect individuals from discrimination by insurance companies or employers based on genetic profile.

An illustration shows test tubes next to a color-coded line graph. A photo

shows two men and two women with a question mark overlaid on each. The text reads: D N A testing can be used to determine whether any of these individuals carry a mutation in the B R C A 1 gene. If any individual in this family gets a positive result, everyone else can figure out their risk of carrying the mutation. If an individual tests positive, what should he or she do? What happens if an individual finds a mutation in the B R C A 1 gene which is not known to be associated with cancer?

Mendel's Laws. Mendel's First Law: Alleles of a gene segregate equally into gametes (eggs and sperm). Mendel's Second Law: Alleles of

different genes segregate into gametes independently of each other.

Step 2 shows a schematic of the chromosomes of Ruth and Isaac. The text reads: The B R C A 1 wild-type and mutant alleles segregate equally into gametes. The schematic shows Ruth's chromosomes separating into two separate strands: one with normal allele and another with mutant allele. The schematic also shows Isaac's chromosomes separating into two separate strands: one with normal allele and another with mutant allele. Next, a 2 by 2 Punnett square shows the four possible offspring of Isaac and Ruth as follows: a homozygous wild-type

(both normal alleles); two heterozygous (each with one normal and one mutant allele); and a homozygous mutant (both mutant alleles). Text reads, Genes and development: Homozygous mutant B R C A 1 embryos do not develop normally and are not viable.

Another text reads, In addition to B R C A 1 on chromosome 17, B R C A 2 on chromosome 13 is known to increase the risk of breast cancer. Alleles of the B R C A 1 gene and alleles of the B R C A 2 gene segregate into gametes independently of each other.

Step 3 shows the offspring of Ruth and Isaac. There is one unaffected

daughter named Harriet (one mutant and one normal allele) and two affected daughters named Lily (one mutant and one normal allele) and Becky (both normal alleles). Text corresponding to Harriet and Lily reads, These two individuals both carry the same mutation in the B R C A 1 gene, but only one goes on to develop breast cancer. Text corresponding to Becky reads, This individual develops breast cancer, but does not carry a mutation in the B R C A 1 gene. Also, there is one unaffected son named Adam (one mutant and one normal allele on chromosome 17 and both normal alleles on chromosome 13), who is linked with a female named Leah (both normal

alleles on chromosome 17 and one B R C A 2 and one normal allele on chromosome 13).

Genes and the Environment: Most traits, including cancer, result from the interaction of many genes and the environment. Three photos show a woman hiking, a woman walking, and a woman smoking.

Return to Visual Synthesis 5.1 THE COMBINED EFFECTS OF GENES AND THE ENVIRONMENT IN DETERMINING PHENOTYPES

Extended description for: Figure 30.1 Tay-Sachs disease

Healthy neuron: The illustration shows a balloon shaped cell body with several tube-like projections, one of which is encased in a sheath. Inside the cell body, several

organelles are depicted, but only 2 lysosomes are labeled. These are look like small spheres.

Neuron affected by Tay-Sachs: The illustration is similar to the healthy neuron except the lysosomes are much larger and lumpy looking. They are labeled, Bulging lysosomes.

Return to Figure 30.1 Tay-Sachs disease

Extended description for: Figure 30.4 Nondisjunction

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

(a) Meiosis: The illustration shows a cell (2 n) in metaphase 1 with two X-

shaped chromosomes aligned at the center. Next, the cell divides into two daughter cells during metaphase 2 with each cell (1 n) having one X-shaped chromosome aligned at the center. Finally, each daughter cell divides into two gametes (1 n) with each containing one rod-shaped chromosome.

(b) Meiosis 1 with first-division nondisjunction: The illustration shows a cell (2 n) in metaphase 1 with two X-shaped chromosomes aligned at the center. Next, first-division nondisjunction occurs, causing the cell to divide into two daughter cells during metaphase 2. The first daughter cell (2 n) contains two X-

shaped chromosomes aligned at the center while the second daughter cell (0 n) has no chromosomes. Finally, each daughter cell divides into two gametes. The first daughter cell produces two gametes (n plus 1) with each containing two rod-shaped chromosomes. The second daughter cell produces two gametes (n minus 1) with each having zero chromosomes. Corresponding text reads, Nondisjunction results in gametes with an extra chromosome and gametes that are missing a chromosome.

(c) Meiosis 2 with second-division nondisjunction: The illustration shows a cell (2 n) in metaphase 1 with

two X-shaped chromosomes aligned at the center. Next, the cell divides into two daughter cells during metaphase 2 with each cell (n) having one X-shaped chromosome aligned at the center. Finally, each daughter cell divides into two gametes. The first daughter cell produces two gametes (n) with each containing one rod-shaped chromosome. The second daughter cell undergoes second-division nondisjunction and produces two gametes: one with two rod-shaped chromosomes (n plus 1), labeled extra chromosome; and another with no chromosome (n minus 1), labeled missing chromosome.

Extended description for: Figure 31.1 Nucleotides

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

At the top, a five-membered ring labeled “ribose sugar” has O substituted for C at the top position. C

1 prime at the upper right vertex is bonded to a base (A, G, U, or C) above and to H below, C 2 prime is bonded to H above and to highlighted O H below, C 3 prime is bonded to H above and O H below, C 4 prime is bonded to C 5 prime above and H below, and C 5 prime is bonded to 2 H and to O in a yellow circle representing that it is part of a phosphate group. This O is further bonded to P that is bonded to O minus above, bonded to O minus to the left, and double bonded to O below. At the bottom, a similar structure is shown that differs only in that the five-membered ring is labeled “deoxyribose sugar” and has C 2 prime is bonded to highlighted H

instead of O H and C 1 prime is bonded to a base (A, G, T, or C).

Return to Figure 31.1 Nucleotides

Extended description for: Figure 31.2 Bases found in DNA and RNA

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

From left to right, part a shows the structures of the pyrimidine bases: cytosine, thymine, and uracil. Cytosine (C) is a six-membered ring with N substituted for C at the bottom

vertex at position 1 with a red bond extending down, C 2 at the lower right vertex double bonded to O, N substituted for C at the upper right vertex at position 3, a double bond at the upper right between positions 3 and 4, C 4 at the top vertex bonded to N H 2, and a double bond at the left side between C 5 and C 6. Thymine (T) is similar to cytosine except that N is substituted for C at position 3 and bonded to H, there is no double bond between C 3 and C 4, C 4 is double bonded to O, and C 5 is bonded to C H 3. Uracil (U) is similar to cytosine except that N substituted for C at position 3 is bonded to H, there is no double bond between C 3 and C 4, and C 4 is double bonded to O.

From left to right, part b shows the structures of the purine bases: guanine and adenine. Each of these bases has a five-membered ring that has a double bond at its right side shared with the left side of a six-membered ring. Guanine (G) has N substituted for C at the bottom vertex at position 9 of the five-membered ring with a red bond extending down, a double bond at the upper left side between positions 7 and 8, N substituted for C at the upper left vertex at position 7, and a shared double bond at the right side between C 4 and C 5. The six-membered ring has N substituted for C at the upper right vertex at position 1 and bonded to H, C 2 at the lower right side

bonded to N H 2, N substituted for C at the bottom vertex at position 3, a double bond at the left side between positions 4 and 5, and C 6 at the top vertex double bonded to O. Adenine is similar except that the six-membered ring has N substituted for C at position 1 with no bond to H, C 2 is not bonded to N H 2, C 6 is bonded to N H 2, and there is a double bond between C 1 and C 6 at the upper right side.

Accompanying text reads, “In a nucleic acid, each base is attached to either a ribose or a deoxyribose by the bond indicated in red.”

Return to Figure 31.2 Bases found in

DNA and RNA

Extended description for: Figure 31.3 The structure of DNA

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A vertical double helix has sides depicted as ribbons. One of these

ribbons is labeled “sugar-phosphate backbone.” From top to bottom, there are paired rods extending from each ribbon to meet in the middle. There are four different colors of rods, each with a slightly different shape. These are labeled “base pairs.” The short green rod always pairs with the longer purple rod and the short yellow rod always pairs with the longer orange rod, showing that the bases always pair in a particular way.

Return to Figure 31.3 The structure of DNA

Extended description for: Figure 31.4 Base pairing

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

At the top, adenine (A) is joined by thymine (T) by two double bonds illustrated by highlighted dashed lines. Adenine consists of a six-membered ring with its upper left

side shared with the lower right side of a five-membered ring. The five-membered ring has N substituted for C in position 9 at the lower left and bonded to deoxyribose, N substituted for C at position 7, a double bond between C 8 and N substituted for C at position 7, and a double bond shared with the six-membered ring between C 4 and C 5 at the lower right side. The six-membered ring has N substituted for C at position 3 at the lower left side; a double bond between N at position 3 and C 2; highlighted N substituted for C at position 1; a double bond at the upper right side between C 1 and C 6; C 6 at the upper right bonded to N H 2; and a double bond between C 4 and C 5

shared with the five-membered ring. Thymine is a six-membered ring with N substituted for C at position 1 at the lower right and further bonded to deoxyribose; C 2 at the lower left vertex double bonded to O; N substituted for C at the left side vertex at position 3 and further bonded to highlighted H; C 4 double bonded to highlighted O; C 6 bonded to C H 3 at the upper right vertex; and a double bond at the upper right side between C 5 and C 6. There are dashed hydrogen bonds between the highlighted N at position 1 of adenine and a highlighted H bonded to N in position 3 of thymine and between a highlighted H bonded to the right of N bonded to C 6 of the six-membered

ring of thymine and the highlighted O double bonded to C 4 of thymine.

At the bottom, guanine (G) is joined to cytosine (C) by three double bonds. Guanine is a double-ring structure with a six-membered ring that shares a double bond at its upper left side with the lower right side of the five-membered ring. The five-membered ring has N substituted for C at the lower left side at position 1 and further bonded to deoxyribose, a double bond at the upper left side between C 2 at the upper left and N substituted for C at the top vertex at position 3, and a double bond between C 4 and C 5 shared with the six-membered ring. The six-

membered ring has N substituted for C at the right side and bonded to highlighted H, C 2 bonded to N H 2, a double bond at the bottom between C 2 and N substituted for C at position 3, a double bond between C 4 and C 5 shared with the five-membered ring, and C 6 double bonded to highlighted O. Cytosine is a six-membered ring with N substituted for C at the lower right at position 1 and further bonded to deoxyribose, C 2 double bonded to highlighted O, highlighted N substituted for C at the left side vertex at position 3, a double bond between positions 3 and 4, C 4 bonded to N H 2, and a double bond between positions 5 and 6. There are dashed lines representing hydrogen bonds

between a highlighted O bonded to C 6 of guanine and a highlighted H bonded to N bonded to C 4 of cytosine between highlighted H bonded to N in position 1 of guanine to highlighted N in position 3 of cytosine, and from a highlighted H of N H 2 bonded to C 1 of guanine to the highlighted O double bonded to C 2 of cytosine.

Extended description for: A flowchart illustrates an experiment to determine whether nucleic acids or protein carries genetic information

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Liquid from a flask containing virulent bacteria extract is added to four other flasks containing nonvirulent bacteria. Text accompanying the initial flask reads, “D N A, R N A, and protein are extracted from heat-killed virulent cells and purified to make a solution.” The test tubes used to add material to each flask are labeled to indicate what was added to each flask. From left to right, these test tubes are labeled “Solution only; Solution plus R Nase; Solution plus protease; Solution plus D Nase.” Beneath each test tube, there is a flask with liquid labeled “nonvirulent bacteria.” Text to the right reads, “The enzymes D Nase, R Nase, and protease, which degrade D

N A, R N A, and protein, respectively, are added to the solution." Arrows point down from each flask to show the result. From left to right, the results after adding solution only, solution plus R Nase, or solution plus protease yielded a flask of virulent and nonvirulent bacteria. Text below reads, "The control solution of killed but untreated virulent bacteria transforms nonvirulent bacteria into virulent bacteria. So do the solutions treated with R Nase and protease." The final flask, which received solution plus D Nase, contains only nonvirulent bacteria. Text below reads, "The solution with D Nase does not transform nonvirulent bacteria into virulent bacteria."

Return to A flowchart illustrates an experiment to determine whether nucleic acids or protein carries genetic information

Extended description for: Figure 31.5 DNA replication

A horizontal double helix consists of ribbons representing the sugar-phosphate backbone with rods extending inward to join the strands together, representing the nitrogenous bases. Each rod from one

strand is met by a rod from the other strand. The upper strand is labeled “3 prime” on the left and the lower strand is labeled “5 prime” on the left. Text above reads, “Parental strands serve as templates for the daughter strands.” About halfway across the illustration, the two strands separate with one half angling up to the right and one half angling down to the left. There are short pieces of ribbon backbone connecting the parental double helix to each of these angled pieces of helix and these are labeled “parental strands.” The angled strands resemble the parental strand and are labeled “daughter strands.” The upper daughter strand has a free end labeled “5 prime” beneath the part

that continues from the parent and the ends of its upper right and left strands are labeled “5 prime” and “3 prime,” respectively. The bottom angled daughter strand is similar except the free end is labeled “3 prime.” It also has ends labeled “5 prime” above and “3 prime” below.

An illustration shows hands holding a highly twisted rubber band. The right hand, on the left of the illustration, is turning the rubber band to the left as indicated by a circular arrow. From left to right, the tightly twisted rubber band forms a loose upward circle, then runs straight, then forms a downward protrusion of several coils labeled “supercoil,” then runs

horizontally across a region labeled “coil” before forming a small protrusion of coils downward, then straightens and forms an upward loop before reaching the right side.

Extended description for: Figure 31.8 Bacterial nucleoid

Photo: Dr. Klaus Boller/Science Source
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

At the top, a micrograph shows a

bacterium as a horizontal roughly rectangular shape with rounded edges and a rough texture. It has a lighter colored circular structure labeled “nucleoid” that is attached at the bottom center and extends just over halfway across its width. There are lines within this circular structure. An arrow points down to an illustration showing a close-up of the nucleoid. The close-up shows a circular core region that is darker at the edges than at the center and is surrounded by a layer of twisted blue lines inside a layer of three vertical rows of red ovals representing proteins. Each red oval has a strand of twisted blue coils extending from it, much like the coils inside the central

region, labeled “supercoiled D N A.” Some of the D N A branches near the ends. There appears to be a coil of D N A emerging from each protein.

Return to Figure 31.8 Bacterial nucleoid

Extended description for: Figure 31.9 A chromosome paint of chromosomes from a male human

Part a shows a roughly spherical

region of brightly colored chromosomes. Each chromosome consists of a strand, generally with a narrow point visible joining two parts that are sometimes the same size and sometimes different sizes. Some of the chromosomes are slightly curled or bent. Karyotype shows the condensed chromosomes painted with fluorescent dyes.

Part b shows the same chromosomes arranged in a karyotype with the chromosomes paired and with the largest chromosomes at the upper left. The top row contains paired chromosomes 1 through 5, the second row contains paired chromosomes 6 through 12, the third row contains

paired chromosomes 13 through 18, and the bottom row contains paired chromosomes 19 through 22 as well as a long X chromosome and a very short Y chromosome. Each pair of chromosomes is stained a different fluorescent color from the other pairs. The chromosomes are generally vertical, but some are slightly bent or curved.

Return to Figure 31.9 A chromosome paint of chromosomes from a male human

Extended description for: Figure 31.10 Chromosome packaging

Morris, et al, Biology for the AP® Course, 1e, © 2022 BFW High School Publishers

The illustration begins at the upper left with an almost horizontal double helix of D N A with ribbons

representing the two sides and bars representing the nitrogenous bases extending from each side to meet in the center. This double helix coils down and to the left to meet a close-up showing a nucleosome. The nucleosome consists of a red disk-like structure with two blue strands of D N A wound around it. There are evenly sized pieces of red visible above, in the middle, and below the D N A strands. The red portion is labeled “histone proteins.” The top strand of D N A extends left to meet another nucleosome from which a strand of D N A extends to another nucleosome. This continues as the nucleosomes become smaller and meet a thick structure with multiple layers of

nucleosomes. Nucleosomes are visible forming a top layer, a side layer, and a bottom layer that run horizontally to the left and then coil down and curve to run to the right. This structure bends up, then down, then up to join a purple coil that resembles a thick thread of many repeating disks. This coil runs repeatedly up and down, forming loops. The overall structure runs right, then bends down, then coils to the left and stretches out to form a series of large loops each appearing as a single strand coiled over and over in repeating smaller loops. This strand of large loops made up of small loops runs left and then bends down and to the right. It becomes a

single wavy thread that runs to join thready material in the very tip of an X-shaped chromosome with five other chromosomes beneath it.

Return to A four-part illustration labeled a through d shows different D N A base pairings

Extended description for: Figure 32.1 DNA replication

A horizontal piece of D N A double helix is depicted on the left with ribbons representing the backbone and dashed rods extending inward to represent the paired bases. Each base meets a base from the opposite strand. The upper left end of the

ribbon is labeled “3 prime” and the lower left end of the ribbon is labeled “5 prime.” This part of the structure is labeled “original (parental) D N A.” Approximately halfway across, the two halves separate with one angling up to the right and one angling down to the right. The place where the halves split is labeled “replication fork.” After a short almost vertical piece of parental D N A, the daughter strand to the upper right has a new lighter colored piece of backbone representing newly added bases. The 5 prime end of this strand is at the lower left, near the replication fork. At the right end of this upper right daughter strand, the parental strand is at the top right and labeled “5

prime” and the new strand below is labeled “3 prime.” This part of the structure is labeled “new (daughter) D N A.” The strand to the lower right is similar. The lighter ribbon representing the new backbone begins at its 3 prime end near the replication fork. At the lower right, the new strand is labeled “5 prime” above and the parental strand is labeled “3 prime” below. This part of the structure is labeled “new (daughter) D N A.”

Return to Figure 32.1 DNA replication

Extended description for: Figure 32.2 Base pairing

Two horizontal bars represent original (parental) D N A. From left to right, the top bar is labeled “A G A C T C A G G.” The bottom bar is labeled “T C T G A G T C C.” An arrow points right to show the same two bars but moved far apart, with one much higher and one much lower. An arrow points right to show that each bar now has a second strand of new

(daughter) D N A. The upper strand has a top strand of parental D N A and a bottom strand of daughter D N A and the bottom strand has a top strand of daughter D N A and a bottom strand of parental D N A. Both new D N A molecules have the same top and bottom base sequences as the original parent D N A.

Return to Figure 32.2 Base pairing

Extended description for: A figure shows how D N A grown in light superscript 14 N medium can be distinguished from D N A grown in heavy superscript 15 N medium by examining their density

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Two vertical strands of D N A are illustrated. The left strand has two pale strands and is labeled “light/light.” The right strand has two dark strands and is labeled “heavy/heavy.” There is a centrifuge tube beneath each double helix. The left tube has a light band just over three-quarters of the way to the top and is labeled

“1.708,” which represents the density (gram per centimeter cubed). The right tube has a dark band about one-quarter of the way to the top and is labeled “1.722.” Horizontal lines extend from each band to the equivalent location on the other tube, emphasizing that the light band is well above the dark band. All data are approximate.

Return to A figure shows how D N A grown in light superscript 14 N medium can be distinguished from D N A grown in heavy superscript 15 N medium by examining their density

Extended description for: A figure shows how the mechanism of D N A replication was determined by growing D N A with heavy superscript 15 N medium with light superscript 15 N medium for two generations

A dark vertical strand of D N A is illustrated and is labeled “heavy/heavy.” Below, a centrifuge tube is illustrated with a dark band at one-quarter of its height labeled “1.722,” representing its density (gram per centimeter cubed). An arrow labeled “first generation” points right to two vertical helices of D N A, one above the other. Each has one dark strand and one light strand and they are

labeled “light/heavy.” The centrifuge tube below has a medium-dark band about halfway up labeled “1.715.” An arrow labeled “second generation” points right to two sets of vertical helices of D N A, each depicted one above the other. The left set each has one dark strand and one light strand and is labeled “light/heavy.” The right set has two light bands and is labeled “light/light.” The centrifuge tube beneath these four D N A molecules shows a light band at just over three-quarters the height of the tube labeled “1.708” and a medium-dark band halfway up the tube labeled “1.715.” Horizontal lines extend from the bands in the tubes across all three tubes to show how they are spaced

out. All data are approximate.

Return to A figure shows how the mechanism of D N A replication was determined by growing D N A with heavy superscript 15 N medium with light superscript 15 N medium for two generations

Extended description for: Figure 32.3 Eukaryotic DNA replication

A chromosome is illustrated at the top

as a horizontal X shape with the two halves joined in the center and with a blue double helix visible inside the chromosome outline. This chromosome is labeled “unlabeled.” An arrow labeled “first generation” points down to show a similar chromosome in which one strand of the double helix is blue and the other is brown. This D N A is labeled “half-labeled.” An arrow labeled “second generation” points down to a similar chromosome in which the top half has a double helix that is half brown and half blue and the bottom half has an entirely brown double helix. The half blue and half brown double helix is labeled “half-labeled.” The entirely brown double helix is labeled “fully

labeled." An image of a chromosome below shows a fuzzy light top half and a dark bottom half.

Return to Figure 32.3 Eukaryotic DNA replication

Extended description for: Figure 32.4 Some enzymes involved in DNA replication

A sphere of packed D N A is illustrated to the left and opens into a short horizontal double helix with a green structure wrapped almost all the way around it with a small

opening in front. Text below reads, “Topoisomerase relieves the stress of unwinding.” To the right, the halves of the D N A double helix separate with one angling up to the upper right and one angling down to the lower right. A yellow circle at the point of separation is accompanied by text that reads, “Helicase unwinds the parental D N A strands.” There are short almost vertical pieces of D N A above and below before they angle up and down and these short pieces are each covered by a line of four orange spheres accompanied by text that reads, “Single-strand binding protein stabilizes single strands of D N A.” At the point that the lower strand begins to angle down, a C-shaped structure

extends from the top, across the back and around the bottom. A piece of new D N A extends up above the parental D N A to the left of this structure and ends at its 3 prime end. Accompanying text reads, “D N A polymerase acts at the site of the growing chain to increase the chain length one D N A subunit at a time.” At the very lower right, the 5 prime end of the new strand is visible above the parental strand. There is a similar D N A polymerase at the upper right of the upper half of the fork, where a new 3 prime end is visible above the end of the parental strand. Just before the vertical piece of backbone that links the upper half of the D N A fork to the horizontal piece, there is a

short red region with a free 5 prime end above the parental strand. Accompanying text reads, “D N A polymerase extends an R N A primer (red).”

Return to Figure 32.4 Some enzymes involved in DNA replication

Extended description for: Figure 32.5 DNA synthesis

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows two D N A strands side by side. Except at ends

and where addition is occurring, each nucleotide is depicted as a five-membered ring and a phosphate group along the side with a rectangular base extending from the ring toward the center. Each base is a different size and has a different cutout or protrusion on the end to fit into a complementary base. T is a small square with a protrusion at the lower right that fits into a cutout in A, which is longer. C is a small square with a cutout into which a protrusion from a longer rectangle labeled G fits. The left strand, labeled “template,” is against a background with a triangular protrusion at the top labeled “3 prime” and a triangular cutout at the bottom labeled “5

prime." Beginning from the top, this strand has a highlighted O H group bonded to the upper left vertex of a five-membered ring that has a lower right vertex bonded to T, and its lower left vertex bonded to a circle labeled "P" that is further bonded to the upper left vertex of a five-membered ring. This pattern continues for a total of six nucleotides, ending with a five-membered ring with its lower left vertex bonded to P. From top to bottom, the sequence of bases is T paired with A from the adjacent strand, G paired with C from the adjacent strand, A paired with T from the adjacent strand, C unpaired but with a dashed line to a nearby G, T unpaired, and G unpaired. The right

strand, labeled “daughter,” is against a background with a triangular cutout labeled “5 prime” at the top and a triangular protrusion labeled “3 prime” at the bottom. An arrow pointing down from the 5 prime end of the daughter strand is accompanied by text that reads, “Direction of chain growth.” The daughter strand begins with a circle labeled “P” that is bonded to the upper left vertex of a five-membered ring with its lower right vertex bonded to P and its upper right vertex bonded to the A that is hydrogen bonded to the T of the top nucleotide of the template strand. This pattern continues for a total of three nucleotides with the bottom

nucleotide having a five-membered ring with its lower right vertex bonded to highlighted O H. From top to bottom, the bases extending left from this strand are A bonded to T of the template, C bonded to G of the template, and T bonded to A of the template. A similar nucleotide is below on a similar background with a triangular cutout at the top and a triangular protrusion at the bottom. This nucleotide has an upper right vertex bonded to a circle labeled “P” further bonded to a chain of two more circles labeled “P,” a lower right vertex bonded to O H, and an upper left vertex bonded to G from which an arrow points to C of the template strand to show where it will form a

hydrogen bond. An arrow points from the O H at the bottom of the daughter strand to the space between the circle labeled “P” bonded to the sugar of the single nucleotide and the chain of two circles labeled “P” to its right. An arrow points down from these two circles to show two circles labeled “P” joined together and labeled “pyrophosphate.”

Return to Figure 32.5 DNA synthesis

Extended description for: Figure 32.6 Leading and lagging strands

Morris, et al. *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

At the top of the illustration, there are two blue horizontal parental strands of D N A that separate toward the right end to form a fork. The top strand runs from a triangular protrusion labeled “3 prime” at the

left to a triangular indentation labeled “5 prime” at the right and the bottom one runs in the opposite direction. An arrow, labeled “unwinding,” points from the fork toward the left beneath the double stranded D N A. Within the fork, the parental strands and two strands of complementary newly synthesized D N A are visible. One strand is beneath the upper parental strand and begins with a small red 5 prime piece, then continues as light blue D N A to the 3 prime end beneath the 5 prime end of the parental strand. The bottom strand has a new strand with a small red 5 prime end at the right with blue D N A to the left until it ends at its 3 prime end. Accompanying text reads,

“Unwinding of the D N A molecule results in a replication fork.” Below, a similar structure has a larger replication fork and the arrow pointing left has moved farther to the left. An arrow points right beneath the top newly synthesized strand, which is straighter but no longer, and an arrow points left along the bottom newly synthesized strand, which extends farther into the new replication fork. The space between these arrows is labeled “elongation.” Accompanying text reads, “Replication always occurs in the 5 prime to 3 prime direction. The daughter strand on top elongates from left to right, and the one on the bottom from right to left.” The bottom

strand is similar but the replication fork and the arrow beneath has moved even farther to the left. The top parental strand now has two daughter strands beneath it, each with an arrow pointing right below, a small red 5 prime end on the left, and a 3 prime end on the right. The top daughter strand is labeled “lagging strand.” The lower daughter strand, labeled “leading strand,” is the same as before but even longer, with its 3 prime end extending into the replication fork beneath the red 5 prime end of the top daughter strand and with the parental strand beneath it. Accompanying text reads, “Replication of the top strand is discontinuous, whereas replication of

the bottom strand is continuous.”

Return to Figure 32.6 Leading and lagging strands

Extended description for: Figure 32.7 RNA primers

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

There are four stages in this illustration. In the first stage, two

horizontal pieces of blue D N A have split to form a replication fork, the top strand runs from a triangular protrusion labeled “3 prime” to a triangular cutout labeled “5 prime” and the bottom strand runs in the opposite direction. A new piece of light blue D N A is beneath the upper right of the top parental strand and has a 3 prime end on the right and a small red piece on the left. Near the replication fork, a purple enzyme labeled “R N A primase” curves over the top of the parental strand and then curves down to the lower left behind a small red piece labeled “R N A primer” that has its 5 prime end on the left and its 3 prime end on the right. Accompanying text reads, “R N

A primase lays down an R N A primer." Below, a similar structure is illustrated in which there is now a new piece of daughter D N A extending from the primer to a C-shaped D N A polymerase wrapped around the D N A just before the red end of the right piece of daughter D N A. An arrow points right beneath the new D N A toward the D N A polymerase. Accompanying text reads, "D N A polymerase extends the R N A primer." Below, there is a similar structure in which the red piece at the left of the right piece of new D N A has been removed. An arrow points to the red piece above labeled "R N A primer removed." Accompanying text reads, "A different

D N A polymerase removes the primer and replaces it with D N A." Below, the two newly synthesized pieces of D N A are illustrated with a nucleotide added to join them together and with a yellow triangular D N A ligase behind the D N A and wrapped just to the left of the new nucleotide. Accompanying text reads, "D N A ligase joins the two fragments."

Return to Figure 32.7 RNA primers

Extended description for: Figure 32.8 Proofreading

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

An almost horizontal strand of dark

blue D N A has an intact parental strand on top with squares extending down representing bases. On the left side, there is a piece of light blue daughter strand beneath with squares extending upward to join with the parent strand. The left end of the daughter strand is labeled “5 prime” and has two bases attached to red backbone. A C-shaped D N A polymerase encircles most of the D N A near its midpoint, but is open at the front. The 3 prime end of the daughter D N A is visible with the polymerase behind it and a yellow square extending up that is labeled “incorrect nucleotide.” An arrow points right from the end of the daughter D N A. Accompanying text

reads, “Very rarely, an incorrect nucleotide is added.” An arrow points down to show the same molecule except that the nucleotide with the yellow base has been removed with an arrow pointing from its original location to its new location at the lower right. Accompanying text reads, “When this happens, the proofreading function of D N A polymerase removes the incorrect nucleotide.” An arrow points down to show a similar structure with the incorrect nucleotide gone and a correct nucleotide in its place with an arrow pointing to the position where it will go at the end of the daughter strand in front of the polymerase. Accompanying text reads, “Then the

correct nucleotide is added to replace the incorrect one." An arrow points down to show the same molecule except that replication has proceeded and the polymerase is now near the right end above with an arrow pointing right. The daughter strand extends almost to the end of the parental strand. There is a new nucleotide with its 3 prime end to the right just next to the growing strand and two more nucleotides are to the lower right.

Return to Figure 32.8 Proofreading

Extended description for: A figure shows four D N A strands with replication forks

All four strands have a double-stranded left half consisting of two parallel horizontal strands that separate halfway across so that the top strand angles upward and the

bottom strand angles downward. They differ in the pattern of arrows in the replication fork between the separated strands on the right side.

In strand a, the parental strand has a top strand with its 5 prime end on the left and its 3 prime end at the upper right and a bottom strand with its 3 prime end on the left and its 5 prime end at the lower right. There is an arrow pointing from below the 3 prime end at the upper right into the replication fork and a series of two arrows, one after the other, pointing from the replication fork toward the space above the 5 prime end.

In strand b, the parental strand has a

top strand with its 5 prime end on the left and its 3 prime end at the upper right and a bottom strand with its 3 prime end on the left and its 5 prime end at the lower right. There is an arrow pointing from below the 3 prime end at the upper right into the replication fork and a similar arrow pointing from above the 5 prime end at the lower right to the replication fork.

In strand c, the parental strand has a top strand with its 3 prime end on the left and its 5 prime end at the upper right and a bottom strand with its 3 prime end on the left and its 5 prime end at the lower right. There is an arrow pointing from beneath the 5

prime end at the upper right into the replication fork and an arrow pointing from above the lower right 5 prime end into the replication fork.

In strand d, the parental strand has a top strand with its 5 prime end on the left and its 3 prime end at the upper right and a bottom strand with its 3 prime end on the left and its 5 prime end at the lower right. There is a sequence of two arrows, one after the other, pointing from the replication fork to just below the 3 prime end at the upper right. There is a single arrow pointing from just above the 5 prime end at the lower right into the replication fork.

Return to A figure shows four D N A strands with replication forks

Extended description for: Figure 33.1 Transcription

Morris, et al., *Biology for the AP® Course*, 1e,
© 2022 BFW High School Publishers

Two strands of D N A are illustrated. The top strand is labeled “template strand.” Its left end is labeled “3 prime” and its right end is labeled “5 prime.” The bottom strand is labeled “nontemplate strand” with its left end labeled “5 prime” and its right end labeled “3 prime.” The two strands are adjacent on the left with nitrogenous

bases between them. Just to the left of the midpoint, the strands separate to form an open region. A short strand, labeled “R N A transcript,” is depicted connected by nitrogenous base pairs to the upper strand in this open region. The R N A transcript is labeled “5 prime” on the left and “3 prime” on the right from which an arrow points right accompanied by text that reads, “Direction of R N A growth.” The D N A on the left is connected by complementary base pairs and the R N A transcript is connected to the right upper piece of D N A by complementary base pairs, but the D N A has A to T pairs and the R N A has U paired with A in D N A because U is substituted for T in R N A.

Return to Figure 33.1 Transcription

Extended description for: Figure 33.2 Promoters and terminators

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Two parallel strands of D N A are illustrated. The top strand has a left end with a triangular projection labeled “3 prime” and a right end with a triangular cutout labeled “5 prime.” The bottom strand runs in the opposite direction with its 5 prime

end on the left and it 3 prime end on the right. Each strand is mostly dark blue. Near the left end, the top strand has a light pink rectangle just above a darker pink rectangle on the bottom strand. Just before halfway across, the top strand has a light green box just above a darker green box in the bottom strand. Just to the right of the midpoint, the top strand has a darker green box labeled “promoter” above a lighter green box on the bottom strand. A vertical rectangle enclosing a strip just before the right end of this pair of green boxes is labeled “T A T A box.” Text above reads, “Transcription is initiated at a promoter and ends at a terminator. The transcript is synthesized in a 5 prime to 3 prime

direction." Near the right end, there is a darker pink box labeled "terminator" on the top strand and a lighter pink box on the bottom strand. A short strand is depicted above the top strand extending from its 5 prime end above the end of the promoter on the top strand to its 3 prime end just before the start of the terminator on the top strand. A similar strand is depicted beneath the bottom strand beginning with its 5 prime end at the left end of the darker green box of the bottom strand and ending with its 3 prime end just at the start of the dark pink box on the bottom strand. Accompanying text reads, "Which strand is transcribed can differ from one gene to the next."

Return to Figure 33.2 Promoters and terminators

Extended description for: Figure 33.3 Transcription elongation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A large, roughly spherical structure is labeled “R N A polymerase.” It has an opening across the center through which two parallel strands of D N A pass. The top strand, labeled “template D N A strand,” runs from 3 prime on the left to 5 prime on the

right. The bottom strand runs from 5 prime on the left to 3 prime on the right. The two strands of D N A are connected by boxes representing bases. There is a region in the center of the R N A complex where the two strands of D N A separate. A strand of R N A has a 3 prime end near the right end of this bubble and runs just beneath the top strand of D N A to which it is connected through hydrogen base pairing. At the end of the bubble, the R N A extends up to the left to end at its 5 prime end outside of the R N A. It is labeled “R N A transcript.” The R N A polymerase is dark green except for lighter regions above and below the central region with D N A and a small region

between the R N A angling up and out of the R N A polymerase complex and the D N A below. An arrow points right above the double-stranded D N A to the right of the R N A polymerase.

Return to Figure 33.3 Transcription elongation

Extended description for: Figure 33.4 RNA synthesis

A vertical template strand of D N A is illustrated against the background of a box with a triangular protrusion at its 3 prime end at the top and a triangular cutout at its 5 prime end at the bottom. The strand begins with a

yellow sphere labeled “P” bonded to the lower right vertex of a deoxyribose sugar that has a lower right vertex bonded to a base, A, and an upper left base bonded to another P. This pattern continues with four deoxyribose sugars and four phosphate groups, except that the top sugar has an upper right vertex bonded to O H instead of a phosphate. Each base has a different shape. From top to bottom, they are T, G, A, and A. The R N A transcript is depicted against the background of a similar box pointing in the opposite direction with a 5 prime end on top and a 3 prime end at the bottom. At the top, it has a five-membered ring representing a ribose sugar with its

upper right vertex bonded to a chain of three yellow circles labeled “P,” its lower right vertex bonded to a yellow circle labeled “P” further bonded to the upper right vertex of a second sugar, a lower left vertex bonded to O H, and an upper left vertex bonded to A that forms two hydrogen bonds with T from D N A. This pattern continues with the middle sugar bonded to C that is connected to G of D N A by three hydrogen bonds and with a bottom sugar bonded to U that is bonded to A of D N A by two hydrogen bonds. This bottom sugar has a lower right vertex bonded to O H instead of P. An arrow pointing downward along this strand of D N A reads, “Direction of chain growth.” A

single R N A base is depicted below with a sugar, an upper right vertex bonded to P connected by a bond with an X over it to a chain of two circles labeled “P,” with an arrow pointing to the same two circles farther away to show that they leave, a lower right vertex bonded to O H, a lower left vertex bonded to O H, and an upper right vertex bonded to U that is connected by two hydrogen bonds to A of the D N A strand.

The three steps read, “1. Incoming ribonucleotides are accepted if they correctly base pair with the template D N A. 2. The 3 prime O H of the growing strand attacks the high-energy phosphate bond of the

incoming ribonucleotide, providing energy to drive the reaction. 3. The two phosphates of the incoming ribonucleotide are released as pyrophosphate.”

Return to Figure 33.4 RNA synthesis

Extended description for: Figure 33.5 Production of mRNA in prokaryotes and eukaryotes

A prokaryotic cell is illustrated as an oval with four flagella extending from one end and a circular chromosome

in the middle. Below, text reads “D N A” above an arrow labeled “transcription,” the arrow points down to text that reads “m R N A.” A eukaryotic cell is illustrated to the right as a larger structure with the nucleus, nucleolus, nuclear membrane with pores, and endoplasmic reticulum visible inside. Below, text reads “D N A” above an arrow labeled “transcription,” the arrow points down to text that reads “primary transcript,” and below another arrow labeled “R N A processing” points down to text that reads “m R N A.”

Return to Figure 33.5 Production of mRNA in prokaryotes and eukaryotes

Extended description for: Figure 33.6 Transcription and translation in prokaryotes

The illustration shows a prokaryotic cell with flagella extending from one end and a circular chromosome in its

center from which an arrow points to show a close-up of a D N A strand. The top strand is labeled “template D N A strand” and runs from the 3 prime end on the left to the 5 prime end on the right. A complementary strand begins with its 5 prime end on the left and its 3 prime end on the right. The two strands separate in the middle to form an oval open region. A strand of R N A has a 3 prime end aligned with the template strand toward the right end of the open region and runs along the template strand until just before the end of the open region at which point it curves down across the other D N A strand to reach its 5 prime end on the left. Just before its end, there is a rounded

ribosome with a small, flat piece beneath the R N A and a somewhat oval piece above the R N A that is flattened where it meets the R N A. A green, wavy strand is emerging from the ribosome. The ribosome is labeled “ribosome starting to synthesize protein.”

Return to Figure 33.6 Transcription and translation in prokaryotes

Extended description for: Figure 33.7 RNA processing in eukaryotes

An illustration shows a cross section of a eukaryotic cell with a nucleus

from which an arrow points to a double-stranded piece of D N A. The top strand has a triangular cutout on the left and a triangular protrusion on the right and the bottom strand runs in the opposite direction. There are three pale introns in each strand. The complementary introns are the same size but run in opposite directions. The regions between the introns are labeled “exon.” An arrow points down to a primary transcript that resembles the top strand of D N A, except that it is a different color. It has the same introns and exons. Another arrow points down to a similar strand of R N A that has a small yellow piece labeled “G T P cap” on the left side and a chain of five A’s on the right end

labeled “poly(A) tail.” Dashed lines point down from the left and right side of each intron to a single point on an m R N A below, showing where the intron had been located before the exons on either side of it were joined together. This bottom m R N A has a G T P cap, a central region of spliced exons with no introns, and a poly(A) tail. The three introns are visible to the side.

Return to Figure 33.7 RNA processing in eukaryotes

Extended description for: Figure 33.8 Alternative splicing

Two strands of D N A are illustrated and labeled “gene.” The top strand has a triangular cutout on the left and a triangular protrusion on the right and the bottom strand has the reverse. Each strand has alternating introns and exons with four of each per

strand. Below, an arrow points down to show a primary transcript that resembles the top strand except that the exons are labeled from left to right, E 1 through E 4. Below, arrows point down to the lower left and lower right beneath text that reads, “alternative splicing.” To the left, the strand is depicted with dashed lines indicating that E 1, E 2, and E 4 join to form a final, short transcript that yields protein A. To the right, a strand is depicted with dashed lines indicating that E 1, E 2, and E 3 are joined to form a final, short transcript that yields protein B.

Return to Figure 33.8 Alternative splicing

Extended description for: A two-part figure shows a gene containing four exons above a table showing the lengths of four versions of m R N A in part a and a graph plotting m R N A abundance against cricket age in part b

Version	Length (bases)
mRNA 1	861
mRNA 2	825
mRNA 3	729

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows a series of rectangles and boxes attached by lines. They are labeled “Exon 1, 216 b p; Exon 2, 96 b p; Exon 3, 132 b p; Exon 4, 513 b p.” There is a table below with two columns and three rows. From left to right, the column headings are

Version and Length (bases). The data in the table reads, “m R N A 1, 861; m R N A 2, 825; m R N A 3, 729.”

Part b shows a graph. The horizontal axis is labeled “cricket age (weeks)” and ranges from 0 to 7 in increments of 1. Arrows on the horizontal axis indicate that 0 is when the egg laid, 2.1 weeks is when it is hatched, and 7 weeks is when it reaches reproductive maturity. Brackets indicate that 0 to 2.1 weeks on the horizontal axis represents an embryo and 2.2 to 7 weeks represents a juvenile. The vertical axis is labeled “m R N A abundance.” Three curves are illustrated on the graph. The dotted line representing m R N A 1 begins at

0 on the horizontal axis just above the bottom of the vertical axis, runs down slightly to almost touch the horizontal axis at 1.4 weeks, then rises gradually before beginning to rise vertically at 2.2 weeks until it begins to level off near the top of the vertical axis. It runs almost horizontally to the end of the horizontal axis. The dashed line representing m R N A 2 begins at 0 on the horizontal axis just above the dotted line and runs almost horizontally until 2.3 weeks, at which point it rises almost diagonally to 5.8 weeks on the horizontal axis and three-quarters of the height of the vertical axis. It then drops rapidly to end at 6.6 weeks on the horizontal axis just above the bottom of the

vertical axis. The solid line representing m R N A 3 begins at 0 on the horizontal axis and just under halfway up the vertical axis and rises slightly to peak at 1.6 weeks on the horizontal axis and the midpoint of the vertical axis. It then decreases rapidly before beginning to level off at 2.6 weeks on the horizontal axis as it crosses the dashed curve just starting to rise, then decreases to run almost horizontally just above the horizontal axis from 4 weeks to the right end of the graph. All data are approximate.

Return to A two-part figure shows a gene containing four exons above a table showing the lengths of four

versions of m R N A in part a and a graph plotting m R N A abundance against cricket age in part b

Extended description for: Figure 34.1 An overview of translation

A horizontal strand of m R N A has a small triangular cutout labeled “5 prime” on the left and a small triangular protrusion labeled “3 prime” on the right. The very left end of the m R N A is yellow. An arrow points right along the left end of the

m R N A. Squares extend up from the m R N A representing bases. A ribosome is assembled around the m R N A with a flattened oval piece beneath, a more rounded piece above, and flattened where it meets the m R N A. There are three vertical ovals in the ribosome where t R N A molecules join their anticodons with the codons of the m R N A. The first oval pairs the m R N A codon G A G with the t R N A anticodon of C U C, the second oval pairs the m R N A codon G U G with the t R N A anticodon C A C, and the third oval pairs the m R N A codon A A A with the t R N A anticodon of U U U. Each t R N A has a vertical piece extending down to the anticodon and then a top

that protrudes slightly to the left and more to the right. The t R N A in the farthest right oval, with the anticodon U U U, has a growing polypeptide chain attached that begins with L y s and extends to the left to V a l, G l u, S e r, and then M e t. Two t R N A molecules are loose to the left. The one closest to the ribosome has the anticodon A G U and the one farther to the left has the anticodon U A C. To the right of the ribosome, there are three t R N A molecules. Each has an amino acid attached to the protrusion to the upper right. From left to right, their anticodons and amino acids are A C G and C y s, A U A and T y r, and C C A and G l y.

Return to Figure 34.1 An overview of translation

Extended description for: Figure 34.2 Ribosome

Morris, et al., *Biology for the AP® Course*, 1e. © 2022 BFW High School Publishers

The ribosome is a flattened, roughly oval to rectangular shape representing the small subunit beneath a roughly rounded shape representing the large subunit. The two pieces are flattened where they come together. The large subunit is slightly taller on the right than on the

left and contains three vertical rectangular to flattened oval-shaped openings.

Return to Figure 34.2 Ribosome

Extended description for: Figure 34.3 Transfer RNA (tRNA)

Part a shows the structure with a vertical double-stranded piece on top and loops to each side. Most of the structure is purple but the loops are different colors. It begins at the top with a triangular cutout at the 5 prime end, slightly below the 3 prime end to

the right. The 3 prime end is labeled "amino acid attachment site." The left side of the double-stranded piece does not have labeled bases, but squares representing bases are labeled beginning partway down. They are G C G G A U U U. On the right side, there is no base paired with U, and then the bases are A A U U C G C. Next, there are bases with no complementary bases depicted at the very top. From bottom to top, these are A C C A. After the unpaired U on the left side, the strand bends left to form a horizontal paired structure that ends in a loop. From right to left, the bases depicted on the top are A, an unlabeled base, then C U C. No base is depicted beneath A, then C is

beneath the unpaired base, then the remaining bases from right to left are G A G. There is a green loop connecting the top and bottom parts. The lower right half of this structure bends down to form a similar loop. From top to bottom, the left side of this bottom piece has an unlabeled base, then C C A G A. On the right, there is G G U, and then two unlabeled bases. The loop on this bottom piece is gray and labeled “anticodon loop” with three bases labeled “anticodon.” There is a small protrusion to the right and slightly downward, then a similar horizontal piece with a loop on the right. From left to right, the top strand has the bases G A C A C. The bottom strand

has an unlabeled base, and then U G U G. There is a red loop at the end.

Part b shows a three-dimensional ribbon diagram of the same structure. It has a gray-curved portion at the bottom with three bases labeled “anticodon” at the lower right, then a vertical piece with green to the upper left leading to red in the upper left corner. Purple extends to the right to end with an unpaired piece with bases C C A labeled “amino acid attachment site.”

Return to Figure 34.3 Transfer RNA (tRNA)

Extended description for: Figure 34.4 Codon–anticodon base pairing

A horizontal piece of m R N A has a triangular cutout labeled “5 prime” at the left and a triangular protrusion labeled “3 prime” at the right end.

Squares extend upward to represent bases. There are three bases, they are A U G and it is labeled “codon.” A t R N A with an anticodon of U A C is depicted with an arrow indicating that it is moving in to pair with the codon. It has a long piece that protrudes slightly to the upper left and more to the lower right, where it ends at a square labeled “M e t,” which represents an amino acid. An arrow labeled “translation” points downward. This yields the same m R N A with the anticodon positioned so that its bases pair with the codon. The left side of the anticodon is labeled “3 prime” and the right side of the anticodon is labeled “5 prime.”

Return to Figure 34.4 Codon–anticodon base pairing

Extended description for: Figure 34.5 Aminoacyl tRNA synthetase

An aminoacyl t R N A synthetase is depicted to the right. Three different free amino acids, G l n, V a l, and I l e, are depicted as three different shapes above three uncharged t R N A, each with a different set of three bases labeled at the bottom and

representing the anticodon. These anticodons are G U U, C A C, and U A G. Each t R N A has a long piece that ends with a slight protrusion to one side and a longer protrusion to the other side. An arrow points from the amino acid with the anticodon U A G to a cutout in aminoacyl t R N A synthetase into which it fits. An arrow shows that I l e fits into a space against the larger protrusion on the side of the t R N A opposite the anticodon. This brings the amino acid and t R N A together.

The column headers from left to right read, “first position (5 prime end); second position; third position (3 prime end).” The table shows the codons of the first position (5 prime end) from top to bottom in the first

column as U, C, A, and G. The second position codons from left to right are U, C, A, and G. The third position (3 prime end) codons from top to bottom in the last column are U C A G, U C A G, U C A G, and U C A G.

In the first row, column U reads, “U U U, Phe; U U C, Phe; U U A, Leu; U U G, Leu”; column C reads, “U C U, Ser; U C C, Ser; U C A, Ser; U C G, Ser”; column A reads, “U A U, Tyr; U A C, Tyr; U A A, Stop; U A G, Stop”; column G reads, “U G U, Cys; U G C, Cys; U G A, Stop; U G G, Trp.”

In the second row, column U reads, “C U U, Leu; C U C, Leu; C U A, Leu; C U G, Leu”; column C reads, “C C U,

Pro; C C C, Pro; C C A, Pro; C C G, Pro"; column A reads "C A U, His; C A C, His; C A A, Gln; C A G, Gln"; column G reads, "C G U, Arg; C G C, Arg; C G A, Arg; C G G, Arg."

In the third row, column U reads, "A U U, lle; A U C, lle; A U A, lle; A U G, Met/Start"; column C reads, "A C U, Thr; A C C, Thr; A C A, Thr; A C G, Thr"; column A reads, "A A U, Asn; A A C, Asn; A A A, Lys; A A G, Lys"; column G reads, "A G U, Ser; A G C, Ser; A G A, Arg; A G G, Arg."

In the fourth row, column U reads, "G U U, Val; G U C, Val; G U A, Val; G U G, Val"; column C reads, "G C U, Ala; G C C, Ala; G C A, Ala; G C G, Ala"; column

A reads, “G A U, Asp; G A C, Asp; G A A, Glu; G A G, Glu”; column G reads, “G G U, Gly; G G C, Gly; G G A, Gly; G G G, Gly.”

Return to Figure 34.6 The genetic code

Extended description for: An illustration shows how an m R N A codes for a polypeptide

An m R N A shows 5 prime end on the left and 3 prime end on the right. It has 30 bases that consist of alternating U and C. Each codon is enclosed in a bracket with an arrow pointing down to an amino acid. This produces a ten-codon polypeptide of S e r, L e u, S e r, L e u, S e r, L e u, S e r, L e u, S e r, and L e u.

Return to An illustration shows how an m R N A codes for a polypeptide

Extended description for: A figure shows three examples of m R N A coding for polypeptides that vary when the reading frames are changed

All of the examples run from 5 prime to 3 prime. The top m R N A has 10 repeating units of U C A. Each is

enclosed in a bracket with an arrow pointing down to indicate that this produces S e r in the amino acid. The polypeptide produced is a chain of 10 S e r. The second m R N A has the same sequence, but the first codon begins with the first amino acid. This produces U that is not in a codon, a chain of nine codons of C A U, and then C A that is not a full codon. Each codon is enclosed in a bracket with an arrow pointing down to show that it produces H i s, yielding a chain of nine H i s. The bottom m R N A has the same sequence, but the first codon begins after U and C. This produces U C, then nine repeating codons of A U C, then A that is not part of a codon. Each A U C is

enclosed in a bracket to show that it produces I l e. This produces a chain of nine I l e.

Return to A figure shows three examples of m R N A coding for polypeptides that vary when the reading frames are changed

Extended description for: Figure 34.7 Translation initiation

A horizontal strand of m R N A has a triangular cutout on the left and a triangular protrusion on the right. It

has small squares extending upward to represent bases. Its left end is surrounded by an oval labeled “small ribosomal subunit.” The left two nucleotides are yellow and meet a purple oblong with three lobes attached beneath the m R N A. An irregularly shaped purple protein is above the ribosome just to the right of this and is labeled “initiation factor.” Immediately to the right of the initiation factor, there is a t R N A with the anticodon U A C paired with three bases of m R N A. The t R N A has a vertical part with a small protrusion to the left and a longer protrusion to the right that ends at a square labeled “M e t.” There are two purple oblongs, one on top of the

other, just to the right of the anticodon. Immediately outside of the ribosome, the bases are A U G G U A A G A. An arrow beneath the small ribosomal subunit points right. An arrow points down to show the next step. The large ribosomal subunit, which is rounded but flat against m R N A, is now attached. The ribosome is now over the bases of m R N A depicted before with A U G directly beneath the anticodon U A C of the t R N A carrying M e t. There are three vertical ovals in the large ribosomal subunit and the t R N A is in the center one. The three purple proteins are depicted to the right with an arrow pointing to show they are moving away.

Return to Figure 34.7 Translation initiation

Extended description for: Figure 34.8 Translation elongation

Morris, et al., *Biology: For the AP® Course*, 1e. © 2022 BFW High-School Publishers

A horizontal strand of m R N A is illustrated with two bases on the left

end depicted in yellow. It has a triangular cutout at the left and a triangular protrusion at the right. There are small squares extending up to represent bases. A ribosome has assembled around it with an oval part below representing the small ribosomal subunit and a rounded part above representing the large ribosomal subunit, both flattened where they meet the m R N A. There are three vertical ovals in the large subunit of the ribosome. An arrow points to three irregular purple proteins leaving to the left. Some of the m R N A bases are labeled beginning in the middle oval. From left to right, they are A U G G U A A G A. The codon A U G is bonded to the

U A C anticodon of a t R N A with a vertical piece that has a slight protrusion to the left and a longer protrusion to the right that ends at a green square labeled “M e t.” Another t R N A is depicted with V a l attached with an arrow showing that it is bringing its C A U anticodon to bind with the m R N A codon in the right oval, which is G U A. An arrow points down to show that the new t R N A has bonded its anticodon to the m R N A codon and the M e t from the first t R N A has bonded to V a l of the new t R N A. A second arrow points down to show a similar structure with an arrow pointing to the right to show that the ribosome is moving along the m R N A. The first t R N A with an

anticodon of U A C is depicted with an arrow indicating that it is leaving to the left with no amino acid. The central oval now contains the codon G U A bonded to C A U of the newly arrived t R N A. To the right, t R N A carrying A r g and with an anticodon of U C U is depicted with an arrow pointing into the right oval above the codon A G A. A third arrow points down to show that the new t R N A has moved into the third oval and bound its U C U anticodon to the A G A codon of m R N A. The polypeptide chain has moved to bind to its A r g, so the new t R N A has a chain of A r g bonded to V a l bonded to M e t.

Return to Figure 34.8 Translation

elongation

Extended description for: Figure 34.9 Translational termination

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A ribosome is attached to a horizontal m R N A that has a large ribosomal subunit on the top and a small ribosomal subunit on the bottom. The ribosome has three vertical ovals. From left to right, the bases in the

ovals are A G A, A C C, and red-highlighted U A A. There are two yellow nucleotides at the 5 prime end of the m R N A on the left and its 3 prime end is on the right. A t R N A is in the middle oval with its anticodon U G G paired to the m R N A codon A C C. This t R N A is bound to T h r that begins a polypeptide chain. This T h r is bound to A r g, V a l, G l y, M e t, A l a, and P h e. A release factor, which has a rounded top with an oval protrusion below angled to the left, is depicted with an arrow pointing into the empty oval above U A A.

Return to Figure 34.9 Translational termination

Extended description for: Figure 34.10 Translation in eukaryotes and prokaryotes

Eukaryotes are illustrated in part a. A horizontal piece of m R N A has a small yellow G T P cap on the left side, a red piece, a short green A U G codon, a red piece, a short purple stop codon, and then a red piece before it ends at its 3 prime end on the right. All of the red pieces are the same length. A ribosome is depicted

to the left with a rounded large subunit above an oval small subunit, both are flattened where they join. An arrow points from the ribosome to the yellow G T P cap, and an arrow points right along the first red piece. A bracket enclosing the red piece between the A U G codon and the stop codon leads to a polypeptide chain of 11 green squares bonded to N H 2 to the left and to C O O H to the right.

Prokaryotes are illustrated in part b. A horizontal m R N A shows that its 5 prime end is on the left and its 3 prime end is on the right. There is a small red piece on the left, then a small yellow square next to a small green square. The yellow square is a

ribosome-binding sequence and the green square is an A U G codon. A ribosome is depicted with an arrow pointing to the yellow square. There is a red piece, then a small purple square. A bracket encloses the red piece and points to polypeptide 1, which is a chain of 10 green squares bonded to N H 2 on the left and C O O H on the right. There is a shorter red region to the right of the purple square on m R N A, then a similar sequence with a small yellow square joined to a small green square, followed by a red region and a small purple square. A ribosome is depicted with an arrow pointing to the yellow square. A bracket encloses the red region between this and the purple

square and an arrow points down to polypeptide 2, which is a chain of 14 green squares bonded to N H 2 to the left and to C O O H to the right. There is a red piece, and then another segment with a small yellow square adjacent to a small green square with a red piece before a small purple square. A ribosome points to the yellow square and a bracket enclosing the red portion points to polypeptide 3, which is a chain of 16 green squares bonded to N H 2 to the left and C O O H to the right. Next, there is a short red region, then a small yellow square next to a small green piece at the 3 prime end on the right.

Return to Figure 34.10 Translation in

eukaryotes and prokaryotes

Extended description for: Visual Synthesis 6.1 GENE EXPRESSION

A flowchart on top depicts the following events. D N A undergoes transcription to form R N A, which undergoes processing to form m R N A. An arrow continues off of the screen. Text accompanying the arrow that represents transcription reads,

“During transcription, R N A polymerase reads a D N A sequence and produces a complementary, antiparallel strand of R N A.” Text accompanying the arrow that represents R N A processing reads, “In eukaryotes, the primary R N A transcript is modified in the nucleus, creating mature m R N A and noncoding R N A.” The m R N A undergoes transport to form another m R N A that undergoes translation to form protein. The events that take place are depicted within a nucleus with its envelope and some pores visible at the bottom of the illustration. From the transcription arrow, there is a long circle of D N A that curves down into a green roughly

spherical R N A polymerase where a red piece of R N A is emerging. The D N A continues back to R N A in the flowchart above. The R N A has a small yellow end labeled “primary transcript (R N A).” Below, a circle shows an R N A polymerase with D N A inside and beneath it an arrow pointing right is labeled “R N A polymerase movement.” Accompanying text reads, “1. Transcription begins at a promoter and continues until a terminator is encountered.” A large, roughly spherical structure is labeled “R N A polymerase.” It has an opening across the center through which two parallel stands of D N A pass. The top strand, labeled “template D N A,” runs from 3

prime on the left just before a small green promoter region to 5 prime on the right. The bottom strand runs from 5 prime on the left to 3 prime on the right just past a short purple terminator sequence. The two strands of D N A are connected by boxes representing bases. There is a region in the center of the R N A polymerase where the two strands of D N A separate. A strand of R N A has a 3 prime end near the right end of this bubble and runs just beneath the top strand of D N A where it is connected through hydrogen base pairing. At the end of the bubble, the R N A extends up to the left to end at its 5 prime end outside of the R N A. It is labeled “R N A transcript.” The R N A polymerase

is dark green except for lighter regions above and below the central region with D N A and a small region between the R N A angling up and out of the R N A polymerase complex and the D N A below. The region between the promoter region and the terminator sequence is enclosed in a bracket labeled “gene.” The primary transcript produced above has an arrow pointing right to a long R N A transcript with a short yellow G T P cap followed by an exon, intron, exon, intron, exon, and then ending with a poly(A) tail. There are two blue spheres on either side of the first intron and near its right end. Text above reads, “2. During R N A processing, introns are removed and

exons are spliced together. The m R N A receives a G T P cap and a poly(A) tail, and then travels out of the nucleus." Above, behind the part of the flowchart representing R N A processing, the nucleolus is visible as a thready sphere and a piece of D N A extends down from it to a ribosome where D N A returns back to the nucleolus and a dark piece of R N A extends to the lower right. Accompanying text reads, "Noncoding R N A's do not encode proteins and include t R N A and r R N A." A black line extends from this t R N A out of the frame to the right. Beneath the primary transcript with introns and exons below step 2, an arrow points to show the first intron

folded into a loop so that the blue spheres come together, then an arrow points to show the same molecule with a P-shaped loop and three spheres moving away. There is a similar set of three spheres arranged in the same way on the next intron. An arrow points down to show that the second intron also leaves as a P shape along with three spheres. Another arrow points down to show R N A moving through a nuclear pore with a line continuing out of the frame and with the G T P cap on its left side still inside the nucleus.

A flowchart depicts transport of m R N A from the nucleus to the cytoplasm, then translation of m R N

A to a protein. Text accompanying the arrow that represents transport reads, “m R N A travels through nuclear pores into the cytoplasm.” Text accompanying the arrow that represents translation reads, “Ribosomes read m R N A to produce polypeptide chains. These chains fold into proteins that carry out vital cellular functions.” Text below protein reads, “Proteins have many different roles in the cell. They provide structural support, act as enzymes that facilitate chemical reactions, and are involved in cell communication.” t R N A’s are visible in the background. The background material in the cell is labeled “cytosol.” An arrow points from inside the nucleus to a t R N A in

the cytoplasm. Another arrow points from the nucleus to a piece of m R N A with many ribosomes along it. Accompanying text reads, “3. A ribosome attaches to the m R N A and scans the transcript for an A U G start codon. The ribosome initiates transcription at that point and synthesizes a polypeptide chain based on the sequence of the m R N A until it reaches a stop codon.” The long strand of m R N A has eight ribosomes along it, each with a large subunit above and a small subunit below, with the protein chain getting larger on each ribosome as they get closer to the right side. To the right, a similar polypeptide unattached to a ribosome is labeled “actin protein.”

Several actin proteins form two lines that join into a growing actin filament of two twisted chains of spheres. An arrow points from the right ribosome into a circle showing a close-up of translation. Accompanying text reads, “4. During elongation, the appropriate t R N A anticodon matches with the available codon on the m R N A, bringing the next amino acid to the polypeptide chain.” A horizontal piece of m R N A is depicted below with a triangular cutout at its 5 prime end on the left and a triangular protrusion at its 3 prime end at the right. Two nucleotides at its left end are yellow. Squares extend up from the m R N A to represent bases. The m R N A has a

small ribosomal subunit below that is a flattened oval and a large ribosomal subunit above that is rounded but flattened where it meets the m R N A. There are three vertical ovals in the large ribosomal subunit. The m R N A bases are labeled within the ovals; from left to right, these are A G A, A C C, G A A. An arrow points from the left oval to a t R N A with a U C U subunit that is moving away. A similar t R N A is in the middle oval with its anticodon, U G G, bonded to the m R N A codon A C C. The t R N A is vertical with a short protrusion to the left and a longer protrusion to the right, where it bonds to T h r at the beginning of a growing polypeptide chain that continues with A r g, V a l,

G l y, M e t, A l a, P h e, V a l, A s p, G l u, G l u, P r o, S e r, T h r, A r g, L e u, and M e t. To the right of the ribosome, there is a t R N A with an anticodon of C U U carrying G l u with an arrow showing that it is moving into the right oval of the ribosome. Below the ribosome is an arrow pointing right labeled “ribosome moves along m R N A in a 5 prime to 3 prime direction.”

Extended description for: Figure 35.1 Gene regulation

	Pancreas cells	Skin cells	Nerve cells
Housekeeping gene	On	On	On
Insulin gene	On	Off	Off
Keratin gene	Off	On	Off

Photos: Ed Reschke/Getty Images
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The three types of cells are pancreas cells, skin cells, and nerve cells. Each is illustrated with a photo. The pancreas cells have many irregular round cells with dark nuclei and a pale circle in the center of the darker cells. The skin cells are depicted as layers with a thin top region of multiple linear layers, a layer of

irregular cells below, and then a base layer where distinct cells are not clearly visible. The nerve cells are dark spots with long branches in many directions. Beneath each cell, it is specified whether three genes are turned on or off. Housekeeping gene: on in all three types of cells. Insulin gene: on in pancreatic cells and off in skin and nerve cells. Keratin gene: on in skin cells and off in pancreas and nerve cells.

Return to Figure 35.1 Gene regulation

Extended description for: Figure 35.2 Positive regulation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows a blue strand of D N A with a round activator protein bound in front of and behind a purple activator binding site just before a short blue piece of D N A and a green polymerase binding site. R N A

polymerase, which has an irregular shape, is bound to the polymerase binding site. There is more D N A to the right of the polymerase binding site. A vertical line extends down from the right end of the polymerase binding site and then to an arrow pointing right to text that reads, “Transcription can occur.”

Part b shows the same D N A but arrows from the activator protein and R N A polymerase are both marked with an X. A vertical line extends down from just past the polymerase binding site to a horizontal line that ends with an X accompanied by text that reads, “Transcription does not occur.”

Return to Figure 35.2 Positive regulation

Extended description for: Figure 35.3 Negative regulation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows a strand of blue D N A with an R N A polymerase complex bound to the green polymerase binding site. There is a short blue

piece, then a brown repressor binding site, then more blue D N A. A vertical line extends down from the right end of the polymerase binding site and meets an arrow pointing right to text that reads, “Transcription can occur.”

Part b is similar except that there is a two-part purple repressor protein over the repressor binding site with half behind and half in front. An arrow pointing from the R N A polymerase to the polymerase binding site is marked with an X. A vertical line extends down from the right end of the promoter to a horizontal line that ends with an X accompanied by text that reads,

“Transcription does not occur.”

Return to Figure 35.3 Negative regulation

Extended description for: Figure 35.4 The lactose operon

A horizontal strand of blue D N A has segments enclosed in boxes and a double line showing a break between the left side and the rest. Before the break at the far left, there is a purple lac I gene. This is enclosed in a box that includes an arrow that points down to a red piece of m R N A from

which an arrow points down to a triangular purple repressor protein. To the right of the break in the D N A, there is a short green segment labeled “promoter (lac P)” above a green box, then a short orange segment labeled “operator (lac O)” above an orange box. There is a short blue segment, then a long yellow segment labeled “lac Z gene” in a big yellow box, a small blue piece, then a long yellow segment labeled “lac Y gene” in a big yellow box, a small blue piece, then a long yellow segment labeled “lac A gene” above a big yellow box. A red piece of R N A extends from within the orange box beneath the operator to the right end. Five arrows point down, from the m R N A in the lac Z

box to a bean-shaped yellow molecule labeled “beta-galactosidase,” from the next blue D N A to the m R N A, from the m R N A in the lac Y gene box to an irregularly shaped yellow molecule labeled “permease,” from the next blue D N A to the m R N A, and from the m R N A in the lac A box to an irregularly shaped yellow molecule labeled “transacetylase.”

Return to Figure 35.4 The lactose operon

Extended description for: Figure 35.5 The lactose operon in the absence of lactose

A horizontal strand of blue D N A has segments enclosed in boxes. At the far left, there is a purple lac I gene. This is enclosed in a box that includes an arrow that points down to a red piece of m R N A from which an

arrow points down to a triangular purple repressor protein. To the right, there is a short green segment labeled “promoter (lac P)” above a green box, then a short orange segment labeled “operator (lac O)” above an orange box. There is a short blue segment, a long yellow segment, a short blue segment, a long yellow segment, a short blue segment, and then a long yellow segment. An arrow shows that the repressor protein binds to the orange operator and an arrow from R N A polymerase to the promoter is marked with a red X.

Return to Figure 35.5 The lactose operon in the absence of lactose

Extended description for: Figure 35.6 The lactose operon in the presence of lactose

A horizontal strand of blue D N A has segments enclosed in boxes. At the far left, there is a purple segment in a purple box that includes an arrow that points down to a red piece of m R N A from which an arrow points

down to a triangular purple repressor protein. There are double-ring structures around the repressor and one fits into the repressor. To the right, there is a short green segment labeled “promoter (lac P)” above a green box with an irregularly shaped R N A polymerase bound to it. An arrow shows R N A polymerase coming in from above. Next, there is a short orange segment labeled “operator (lac O)” above an orange box. A short vertical line extends down from the end of the promoter to an arrow pointing right. There is a short blue segment, then a long yellow segment in a big yellow box, a small blue piece, then a long yellow segment in a big yellow box, a small

blue piece, and then a long yellow segment in a big yellow box. A red piece of R N A extends from within the orange box beneath the operator to the right end. Five arrows point down, from the m R N A in the first yellow box to a bean-shaped yellow molecule, from the next blue D N A to the m R N A, from the m R N A in the next yellow box to an irregularly shaped yellow molecule, from the next blue D N A to the m R N A, and from the m R N A in the last yellow box to an irregularly shaped yellow molecule.

Return to Figure 35.6 The lactose operon in the presence of lactose

Extended description for: Figure 35.7 Transcriptional regulation in eukaryotes

Two strands of D N A are depicted with a slash across the center left to show that a section in the middle is not depicted. The top strand runs from 5 prime at the upper left to 3

prime on the lower right, and the bottom strand runs from 3 prime on the upper left to 5 prime on the lower right. The 5 prime ends are indicated with triangular cutouts and the 3 prime ends are indicated with triangular protrusions. Near the upper right ends of the strands each has a small red box. These boxes run in opposite directions on the top and bottom strands and are labeled "enhancer sequence." The top box has a triangular protrusion on the left and a cutout on the right and the bottom box has the reverse pattern. Slightly farther to the left, there is another pair of these boxes with one in each strand and with the same directions within each strand as before. The D N

A curves around to the left, then back around below. Beneath each enhancer sequence, there is a vertical dumbbell-shaped structure that extends to a large rounded purple structure that extends all the way to the D N A below. This purple structure and the dumbbell-shaped structures are labeled “regulatory transcription factors.” There is an R N A polymerase complex across the bottom center of the D N A with a small pink sphere next to a small blue sphere above the D N A on its left side. On its right side, there is an orange oval structure that narrows to the right with a yellowish orange triangle across its front center and a small yellow sphere to its right with a

space between it. In the D N A below, green bars are labeled “promoter.” From the promoters an arrow points down and to the right and reads, “direction of transcription.” There is one more yellowish sphere to the right of the promoter above the D N A and this and a large reddish orange piece behind it that extends behind the oval piece are labeled “general transcription factors.” The promoter with the transcription factors above is at the bottom to the right of an open region of D N A surrounded by a green circular structure above and below labeled “R N A polymerase complex.” This complex is dark green around the opening in the D N A and around its edges and lighter in

between.

Three numbered steps read, “1. Regulatory transcription factors bind with D N A sequence called an enhancer. 2. Binding of regulatory transcription factors recruits the general transcription factors to the promoter of the gene. 3. The general transcription factors recruit the components of the R N A polymerase complex, and transcription takes place.”

Return to Figure 35.7 Transcriptional regulation in eukaryotes

Extended description for: Figure 35.8 Alternative splicing of an insulin-receptor transcript

The illustration shows a primary R N A transcript that has five exons numbered left to right from 9 to 13

with four introns in between them. Arrows point down to the lower left and right of the illustration. The arrow pointing to the lower left of the illustration indicates m R N A in the liver, an arrow points down accompanied by text that reads, “In the liver, exon 11 is included in the m R N A.” This yields a piece of R N A that includes exons 9, 10, 11, 12, and 13. Exon 11 is highlighted. An arrow points down to a triangular protein labeled “receptor with low insulin affinity.” The arrow pointing to the lower right of the illustration indicates m R N A in skeletal muscle, an arrow points down accompanied by text that reads, “In skeletal muscle, exon 11 is excised from the m R N A.”

This produces an m R N A with exons 9, 10, 12, and 13. An arrow points down to a pink, kidney-shaped molecule labeled “receptor with high insulin affinity.”

Return to Figure 35.8 Alternative splicing of an insulin-receptor transcript

Extended description for: Figure 35.9 RNA editing

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In both parts, m R N A is depicted with its 5 prime end on the left and its 3 prime end on the right. Part a depicts processed apolipoprotein m R N A in the liver. The bases from the

left to right are U A U A U G A U A C A A U U U G A U C A G. An arrow points down to show the same m R N A with each set of three bases enclosed in a bracket with an arrow pointing to the specified amino acid sequence. From left to right, the amino acid sequence is T y r, M e t, I l e, G l n, P h e, A s p, G l n.

Part b depicts processed apolipoprotein m R N A in the intestine. It begins with the same m R N A as in part a. An arrow points down accompanied by text that reads, “In the intestine, a C is edited to U.” This yields an m R N A with the sequence U A U A U G A U A U A A U U U G A U C A G. Each set of bases is

enclosed in a bracket with an arrow pointing down to show the amino acid specified. The first three amino acids are the same and are T y r, M e t, I l e, but the fourth codon has been changed to a stop codon and the protein ends here.

Return to Figure 35.9 RNA editing

Extended description for: Figure 35.10 Features of mRNA that affect gene expression

The illustration shows a single strand of R N A with two loops. There is a triangular cutout at the left end and a triangular protrusion at the right end. From left to right, the features depicted are a small G T P cap, a 5 prime U T R region, A U G at the start of a long region with a ribosome just

past A U G, a long 3 prime U T R region, and five A's representing a poly(A) tail. The ribosome has a rounded large subunit above and a flattened oval subunit below.

Return to Figure 35.10 Features of mRNA that affect gene expression

Extended description for: Figure 35.11 Histone modifications

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows a cross section of a nucleosome that is encircled by two coils of D N A and is filled with histones. The histone tails of amino

acids protrude from the nucleosome. Some of the proteins within the histone are lysine, monomethyl (M e) lysine, trimethyl (M e 3) lysine, and acetyl (A c) lysine. Lysine is depicted as a 25 amino acid chain with the third amino acid highlighted in orange. Monomethyl (M e) lysine is the same as lysine except that the orange amino acid is bonded to C H 3. Trimethyl (M e 3) lysine is similar except that the orange amino acid is bonded to C further bonded to three C H 3. Acetyl (A c) lysine is similar except that the orange group is bonded to C double bonded to O and bonded to C H 3.

Return to Figure 35.11 Histone

modifications

Extended description for: Figure 35.13 Levels of gene regulation in eukaryotes

At the top, labeled “chromatin,” there is a strand of D N A depicted with nucleosomes along it that join

together to form a packed region of nucleosomes. An arrow points down to another level, labeled “transcription,” that has an R N A transcript with a triangular cutout on the left and a triangular protrusion on the right. It has three introns and four exons. An arrow points down to another level, labeled “R N A processing,” to the same transcript as above with an exon and intron indicated. An arrow points away to show the loss of the three introns and an arrow points down to show the production of m R N A with a short yellow cap on the left side and a chain of five A’s on the right side. An arrow points down to show the m R N A moving through a nuclear pore,

depicted as an opening between two curved regions of double-layered membranes labeled “nuclear envelope.” The next level is labeled “translation.” The m R N A is depicted with a ribosome around it with a chain of protein spheres emerging from the ribosome. Below, labeled “post-translational modification,” are three polypeptides that have been modified. From left to right, the modifications are phosphorylation, methylation, and acetylation. In phosphorylation, there is a circle labeled “P” attached to an amino acid. In methylation, there is a C H 3 group attached to the third amino acid. In acetylation, the first amino acid is bonded to C double bonded to O and

bonded to C H 3.

Return to Figure 35.13 Levels of gene regulation in eukaryotes

Extended description for: A figure shows the function of the T r p operon and a graph plotting the T r p E relative expression against the added tryptophan

At the top, six dots are labeled “free tryptophan.” An arrow points to an irregular sphere with dots on it labeled “free tryptophan binds to T r p R.” An arrow points down to show the same sphere with dots bound to

the regulatory region of a piece of D N A. Accompanying text reads, “T r p R with bound tryptophan binds D N A.” To the right, the T r p operon is depicted as a series of five boxes on the D N A. From left to right, these are t r p E, t r p D, t r p C, t r p B, and t r p A. Below an irregular sphere with no dots is labeled “T r p R.” There is nothing bound to the regulatory region before the T r p operon. Just to the left of the T r p operon, there is a short vertical line and then a horizontal arrow pointing right to the label “transcription.” An arrow points from the t r p A box to six dots labeled “free tryptophan.” Text accompanying the arrow reads, “Production of proteins required to synthesize

tryptophan.”

The horizontal axis of the graph is labeled “tryptophan added (millimolar)” and has bars plotted at 0.1, 10, and 20. The vertical axis is labeled “T r p E relative expression” and ranges from 0 to 1.0 in increments of 0.1. The bar for 0.1 millimolar of tryptophan extends to 0.93 with a standard error of 0.05, the bar for 10 millimolar of tryptophan extends to 0.3 with a standard error of 0.1, and the bar for 20 millimolar of tryptophan extends to 0.1 with a standard error of 0.05. All data are approximate.

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A photo of an egg as a totipotent cell shows a translucent circle with a circle inside and a concentric circle outside. From the egg, three arrows point down to three pluripotent cells that each have a visible nucleus each

colored differently. An arrow points from each of these cells to three multipotent cells of the same type. An arrow points from each set of three cells to a specific differentiated cell type. The cell types are an intestinal cell, depicted as a piece of intestinal wall with many thin protrusions to the right; red blood cells, depicted as disk-like red cells; and a nerve cell, depicted as a dark center with many dark branches.

Return to Figure 36.1 Differentiation

Extended description for: A figure shows the steps and results of an experiment to test whether cell differentiation is due to differential gene expression or loss of genes

The illustration shows an unfertilized egg with an arrow of light pointing to

its nucleus. Accompanying text reads, “1. The nucleus of an unfertilized egg cell was inactivated with ultraviolet light.” Below, a Xenopus laevis tadpole is depicted above a text reading, “2. The nucleus from an intestinal cell of a tadpole was injected into the egg cell.” An arrow points from the tadpole to a small pink cell, then an arrow points from this egg cell to join a large arrow from the egg exposed to ultraviolet light that points to a different-colored egg with the new nucleus. Two arrows point away from this new egg. The first arrow points to an X accompanied by a text that reads, “716 experiments: Development terminated prior to tadpole stage.” The second arrow

points to a clump of two cells, from which an arrow points to a clump of four cells, from which an arrow points to a tadpole. Accompanying text reads, “10 experiments: Development to tadpole stage occurred.”

Return to A figure shows the steps and results of an experiment to test whether cell differentiation is due to differential gene expression or loss of genes

Extended description for: Figure 36.2 Results of nuclear transfer experiments

The horizontal axis is labeled “degree of differentiation” and ranges from early embryo on the left to adult on the right. The vertical axis is labeled “percentage of nuclear transplant experiments that succeed” and ranges

from 0 to 50 in increments of 10. The data on the graph are as follows. Near the left end of the graph: early embryo mammal 28 percent, early embryo amphibian 26 percent; one-eighth of the way across the vertical axis: amphibian 22 percent; almost halfway across the graph: mammal 14 percent, amphibian 16 percent; almost two-thirds of the way across the graph: amphibian 5 percent; about three-quarters of the way across the graph: amphibian 4 percent; almost all the way across the graph: adult mammal 2 percent, adult amphibian 3 percent. A curved line begins at early embryo and 30 percent and forms a shallow, concave-up curve to end just at adult slightly

above the horizontal axis. All data are approximate.

Extended description for: A two-part figure shows two possible signaling cascades with part a showing activity in the absence of a pathogen and part b showing activity in the presence of a pathogen

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows a circle with an oval nucleus on the right that contains a horizontal double helix of D N A. To the left, there is a small crescent-shaped molecule labeled “cactus” with a circle labeled “D I F” fitted into

it.

Part b shows a similar cell except that an arrow, accompanied by a curved arrow showing the addition of A T P and loss of A D P, points from Cactus bound to D I F to Cactus with one end bound to a circle labeled “P.” The circle that had been bound to Cactus is shown next to an arrow pointing to the D N A, showing that the circle is attached to the left end of the D N A. A short vertical line points up and meets an arrow pointing right. Just to the right, another short vertical line points up and meets an arrow pointing right. Text above the arrows reads, “Transcription of antimicrobial peptide gene.” An arrow points out of

the nucleus to two squares; the text reads, “Translation of antimicrobial peptides.” An arrow points out of the cell to four squares; the text reads, “Secretion of antimicrobial peptides.”

Return to A two-part figure shows two possible signaling cascades with part a showing activity in the absence of a pathogen and part b showing activity in the presence of a pathogen

Extended description for: Figure 37.1 Silent and missense mutations

Part a is labeled nonmutant and shows a horizontal piece of double-stranded D N A. The sequence of the top strand is C C T G A G G A G, and the sequence of the complementary bottom strand, labeled transcribed strand, is G G A C T C C T C. An arrow labeled transcription points down to show that this is transcribed to a

single strand of R N A, with the sequence C C U G A G G A G. The bases of R N A are bracketed to show codons, each with an arrow pointing down to show translation to an amino acid. The codons and amino acids are as follows: C C U is translated to P r o, G A G is translated to G l u, and G A G is translated to G l u. The final product is P r o, G l u, G l u.

Part b is labeled silent mutation. It shows a similar double stranded D N A molecule as in part a except there is a single highlighted base pair difference. The top strand is C C T G A A (highlighted) G A G, and the bottom strand is G G A C T T (highlighted) C T C. The bottom strand is transcribed to

form a piece of R N A with the sequence C C U G A A (highlighted) G A G. The three sets of three bases on R N A, representing three codons, are again translated, but the highlighted A changes the middle codon from G A G to G A A. However, the product is not changed except that the central G L U is highlighted.

Part c is labeled missense mutation. It shows a similar double stranded D N A molecule in which there is a single highlighted base pair difference from the D N A in parts a and b. The top strand is C C T G A T (highlighted) G A G, and the bottom strand is G G A C T A (highlighted) C T C. The bottom strand is transcribed to form a piece

of R N A with the sequence C C U G A U (highlighted) G A G. The three sets of three bases on R N A again form three codons that are translated, but this time the central amino acid is highlighted V a l instead of G l u. The product is P r o, V a l, G l u.

Return to Figure 37.1 Silent and missense mutations

Extended description for: Figure 37.2 A nonsense mutation

Part a is labeled nonmutant and shows a horizontal piece of double stranded D N A. From left to right, the sequence of bases in the top strand is C C T G A G G A G, and the sequence of bases in the bottom strand, labeled transcribed strand, is G G A C T C C T C. An arrow labeled transcription

points down to show that this is transcribed into a piece of R N A with the sequence C C U G A G G A G. Brackets enclosing sets of three bases representing a codon indicate that C C U is translated to P r o, G A G is translated to G l u, and G A G is translated to G l u. The final product is P r o, G l u, G l u.

Part b is labeled nonsense mutation and shows a similar horizontal piece of double stranded D N A except that it has one base pair difference that is highlighted. The top strand is C C T T (highlighted) A G G A G, and the bottom strand is G G A A (highlighted) T C C T C. An arrow points downward to show that this is translated to m R

N A with the sequence of C C U U (highlighted) A G G A G. Beginning from the left end, two sets of three bases are enclosed in brackets. The left-hand sequence of C C U is translated to P r o. The middle sequence of U (highlighted) A G has a line to stop indicating that it is a stop codon. There is no bracket around the last three bases as they are not translated. The final product is just P r o.

Return to Figure 37.2 A nonsense mutation

Extended description for: Figure 37.3 A small deletion

Part a is labeled nonmutant C F T R

and shows a horizontal double-stranded piece of D N A at the top. Its top strand has the sequence A T C T T T G G T, and its bottom strand, labeled transcribed strand, has the sequence T A G A A A C C A. An arrow points down to show that transcription yields a piece of m R N A with the sequence A U C U U U G G U. The bases are bracketed in sets of three to show that A U C is translated to I l e, U U U is translated to P h e, and G G U is translated to G l y. The protein product is I l e, P h e, G l y. An arrow points down to a horizontal piece of membrane with a cylindrical protein made up of many smaller vertical cylinders running vertically across it to form a channel. A strand

extends through a disk-shaped piece to the lower right, a loop extends through two disk-shaped pieces to the right, and the top of the cylinder has short strands connecting the tops of the smaller vertical cylinders making up the sides of the overall channel, which is labeled C F T R transporter. An arrow pointing up through the channel shows that small green spheres labeled chloride ions move through it from one side of the membrane to the other. Text below reads, The C F T R transporter pumps chloride ions out of the cell.

Part b is labeled mutant C F T R and shows a shorter horizontal piece of D N A at the top. Its top strand has the

sequence A T T G G T, and its bottom strand has the sequence T A A C C A. This is transcribed to produce m R N A with a sequence of A U U G G U. Brackets enclose the left and right three bases to show that A U U is translated to I l e and G G U is translated to G l y. The protein product is I l e, G l y, and a dashed arrow pointing to the line connecting these amino acids is accompanied by text reading, Missing amino acid (P h e). Text below reads, Three nucleotides are deleted in the italicized C F T R end italics gene, resulting in a missing amino acid. An arrow points down to a horizontal piece of membrane with no proteins in it. Text below reads, The mutant C

F T R protein is unstable, and is degraded before reaching the membrane.

Return to Figure 37.3 A small deletion

Extended description for: Figure 37.4 A frameshift mutation

Part a is labeled nonmutant and shows a horizontal double-stranded D

N A template. The top strand of D N A has the sequence C C T G A G G A G A A G T C T G C C, and the bottom strand, labeled transcribed strand, has the sequence G G A C T C C T C T T C A G A C G G. An arrow points down to show that this is transcribed to m R N A with the sequence C C U G A G G A G A A G U C U G C C. Each set of three bases is enclosed in a bracket representing a codon, and this shows that the m R N A is translated as follows. The codons are C C U translated to P r o, G A G translated to G l u, G A G translated to G l u, A A G translated to L y s, U C U translated to S e r, and G C C translated to A l a. The string of amino acids is P r o, G l u, G l u, L y s, S e r, and A l a.

Part b is labeled frameshift mutation (insertion) and shows a similar horizontal double-stranded D N A template with a pair of bases inserted. The top strand of D N A has the sequence C C T C (highlighted) G A G G A G A A G T C T G C C, and the bottom strand has the sequence G G A G (highlighted) C T C C T C T T C A G A C G G. An arrow points down to show that this is transcript to form m R N A with the sequence C C U G (highlighted) C T C C T C T T C A G A C G G. Brackets enclose the sets of bases to show the codons as follows. C C U is translated to P r o, highlighted C G A is translated to highlighted A r g, G G A is translated to highlighted G l y, G A A is

translated to highlighted G l u, G U C is translated to highlighted V a l, and U G C is translated to highlighted C y s. C on the end is part of a bracket continuing on and not shown. The overall protein is P r o, A r g, G l y, G l u, V a l, C y s. All of the amino acids except for the first one, P r o, are highlighted to show that they were changed by the mutation. Text below reads, An insertion or deletion that is not an exact multiple of three nucleotides changes the reading frame of translation.

Return to Figure 37.4 A frameshift mutation

Extended description for: A figure shows how transposition takes place

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

On the left, a horizontal blue chromosome has a circular centromere with a short arm to the left and a longer arm to the right. Just to the right of the centromere on the longer arm, the top chromosome has

a piece with a vertical dark blue bar, then a red bar, then a dark blue bar. The red piece is labeled transposable element. An arrow labeled transposition points right with a vertical red bar across its center to a longer purple chromosome to the right that has a circular centromere, a short arm on the left, and a long arm on the right. An arrow points downward to a similar pair of chromosomes. The blue chromosome on the left now has an entirely dark blue region with dark blue replacing the red region. Text pointing to the place where the red bar is absent reads, transposable element excised. Text below reads, Transposable elements can jump out of a gene,

restoring its normal function. The purple chromosome to its right has a red bar approximately halfway across its long arm. Text below reads, When a transposable element jumps out of a gene and re-inserts elsewhere in the genome, it sometimes disrupts the function of a different gene.

Return to A figure shows how transposition takes place

Extended description for: Figure 37.5 Two alleles of the gene encoding β-globin, a subunit of hemoglobin

The steps of transcription and

translation are depicted for both alleles with the A allele on the left and the S allele on the right. On the top of each side is a horizontal double stranded piece of D N A.

For the A allele, the top strand shows the bases G A G and the bottom strand shows the bases C T C. This is transcribed to m R N A with the bases G A G, which is translated to form G l u in a protein with other amino acids to the left and right. An arrow points down to show a roughly spherical protein with four subunits, two dark subunits to the upper left front and upper right rear and two pale subunits to the lower left rear and lower right front. In the center of

each of the four subunits is a small rectangle with a sphere in the center. A dot indicating G l u is depicted to the upper left and upper right along dark strands of the protein, which is labeled H b A.

For the S allele, the top strand of D N A shows the bases G T (highlighted) G and the bottom strand of D N A shows the bases C A (highlighted) C. This is transcribed to m R N A with the bases G U (highlighted) G. This is translated to a highlighted amino acid labeled V a l bonded to amino acids on each side. It yields a similar protein with four subunits, but the dots labeled G l u are replaced by dots labeled V a l. This protein is labeled H b S.

Return to Figure 37.5 Two alleles of the gene encoding β-globin, a subunit of hemoglobin

Extended description for: Figure 37.6 Conjugation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

On the upper left, a donor bacterial cell is depicted with one large circular chromosome and two small circular pieces of D N A. A long horizontal structure labeled pilus connects this

bacterium to a second bacterium labeled recipient that contains a single large circular chromosome. Below, the two cells are depicted close together with a short horizontal piece connecting them. A small circular piece of D N A in the donor cell next to this connection has an arrow pointing to a similar small circular piece of D N A in the recipient cell, showing that the D N A has been transferred from the donor cell to the recipient cell.

Return to Figure 37.6 Conjugation

Extended description for: Figure 37.7 Transformation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Two bacterial cells are illustrated. The left-hand cell is labeled dead donor and has many loose threads of D N A inside and extending across a dotted line representing its right and lower cell wall and membrane, showing that they are damaged and allowing D

N A to pass through. An arrow points from inside of the dead donor to a single thread of its D N A, from which an arrow points to show the same D N A in an intact recipient cell next to the recipient cell's large main chromosome.

Return to Figure 37.7 Transformation

Extended description for: Figure 37.8 Transduction

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Two bacterial cells are illustrated. The left-hand cell is labeled virus-infected donor. It has a bacteriophage attached to its cell wall, depicted as a hexagon with a cylinder that protrudes into the cell. A coil of genetic material in the hexagon

extends through the cylinder into the cell. The cell contains a large, circular bacterial chromosome that is highlighted and many viral components, including hexagons, cylinders, and genetic material. An arrow points out of the cell through its right side, which has a dashed cell wall and cell membrane to show that it is rupturing, to a viral particle with a strand of red bacterial D N A in its hexagonal part. A similar viral particle with bacterial D N A is below, and two other viral particles contain only viral D N A. An arrow points from the viral particle with bacterial D N A to a similar particle attached to the second bacterial cell, labeled recipient. An arrow shows the

highlighted bacterial D N A being injected into the cytoplasm next to the chromosome of the recipient bacterium.

Return to Figure 37.8 Transduction

Extended description for: Figure 38.1 The polymerase chain reaction (PCR)

The illustration consists of three boxes with arrows pointing from one to the next indicating three steps. The first box shows double stranded D N A that is joined together by hydrogen bonds on the left side and separated into upper and lower strands on the right side. The top strand ends at its 3

prime end and is labeled target sequence (strand A). The bottom strand ends at its 5 prime end and is labeled target sequence (strand B). Accompanying text reads, Denaturation: A solution containing double-stranded D N A (the template) is heated to separate the D N A into two individual strands. An arrow points right to show the next box, which shows the two strands from the original D N A completely separate with one extending horizontally across the top and the other extending horizontally across the bottom. A small piece labeled D N A primer A is connected by hydrogen bonds to the right end of the top strand with its 5 prime end on the left

beneath the 3 prime end of the top strand. The primer is attached by hydrogen bonds (base pairs). Below, a similar small primer labeled D N A primer B is attached by hydrogen bonds to the left side of the lower strand with its 5 prime end above the 3 prime end of the original strand. Accompanying text reads, Annealing: When the solution is cooled, the two D N A primers anneal to their complementary sequence on the strands of the template. An arrow points right to show the same strands, but the primers are now joined to long strands of D N A forming complementary strands to the original strands. The newly added D N A is labeled, Amplified D N A.

Accompanying text reads, Extension: D N A polymerase synthesizes new D N A strands (complementary to the template strands) by extending the primers in a 5 prime to 3 prime direction.

Return to Figure 38.1 The polymerase chain reaction (PCR)

Extended description for: Figure 38.2 PCR amplification

At the top is a horizontal double-stranded piece of D N A with the top strand running 5 prime to 3 prime and the bottom strand running 3 prime to 5 prime. A highlighted

region across most of the D N A is labeled, target sequence. Accompanying text reads, “1. The target sequence is the region to be amplified.” An arrow points down and is joined by a line from ten small pieces of D N A labeled primers. Half of the primers are colored to match the top strand of D N A and the other half are colored to match the bottom strand of D N A. Accompanying text reads, “2. Primers are short stretches of D N A that bind to the ends of the target sequence.” At the end of the arrow, the original piece of D N A is separated with a primer bound to the lower right of the top strand and a primer bound to the upper left of the bottom strand. An arrow points from

the top strand to the lower left and from the bottom strand to the lower right. The left-hand product has the upper parent strand from the original D N A and a new bottom strand with a primer at the lower right. The right-hand product has the lower parent strand from the original D N A and a new top strand with a primer at the upper left. Accompanying text reads, “cycle 1 product, 2 copies.” Arrows point down from each of these products accompanied by curved lines showing the addition of four primers to each. Each set of four primers includes two that are color-coded to match the top strand and two that are color-coded to match the bottom strand. Each arrow points

down to show that the two strands of D N A have separated and there are primers attached to the top and bottom as before. Accompanying text reads, “3. Each round of P C R doubles the number of D N A molecules.” Once again, arrows point down to the left from the upper strand and down to the right from the lower strand for each of the two products of the first cycle. On the left, the product that had the original parent strand on top yields a daughter molecule with the original parent strand on top and a new bottom strand and a product with two new strands. On the right, the product that had the original parent strand on bottom and a new top has one daughter molecule with

the original strand on the bottom and a new strand on top and one entirely new strand. Accompanying text reads, “cycle 2 product, 4 copies.” Arrows point down from each of the four products to a long line of products that all have entirely new strands. Accompanying text reads, “4. After n cycles of amplification, there are 2 superscript n copies of the target sequence. Additional text reads, cycle n product: 2 superscript n copies.

Return to Figure 38.2 PCR amplification

Extended description for: Figure 38.3 Gel electrophoresis

Step 1: D N A is loaded into wells at one end of the gel. A vertical rectangle has four rectangular cutouts across the horizontal top, and the tip of a pipette is adding liquid to the left-hand well.

Step 2: An electric current is applied, resulting in the movement of D N A toward the positive end of the gel. The same gel is depicted, but there is a circle labeled minus above and a circle labeled plus below. There are bands in the vertical lane extending down from each well, showing that D N A is moving in a vertical line. The left-hand lane has three bands close together near the top, then a space, then two bands about evenly spaced between two-thirds and halfway up the gel. The second lane has two bands, one aligned with the second band from the top in the left-hand lane and the other between the third and fourth bands in the left-hand lane. The third lane has two bands,

one halfway between the bands in the second land and one halfway between the fourth and fifth bands of the first lane. The fourth lane has a single band aligned with the top band of the first lane. An arrow to the right points downward.

Step 3: D N A is separated by size, with smaller molecules moving farther than larger molecules. A gel is depicted that has a similar pattern of bands to the gel in the previous step except that the bands are more spread out. The top bands have not moved very much, and the bottom bands have moved over halfway down the gel. A band at the top in the fourth lane is labeled largest, and the band

at the bottom in the first lane is labeled smallest. All data are approximate.

Return to Figure 38.3 Gel electrophoresis

Extended description for: Figure 38.4 A gel

Photo: Guy Tear/Wellcome Images

Four lanes are labeled from left to right as ladder and 1 through 3. On the left, the bands of the lane labeled ladder are labeled with numbers representing size (b p). From top to bottom, the sizes are 3000 at the very top, 2000 at about seven-eighths of the height of the gel, 1600 just above 1400 at about two-thirds the height of the gel, 1000 just above the midpoint of the gel, 800 at the midpoint of the gel, 600 and 500 close together just below the midpoint, and 100 at about one-quarter the height of the gel. Lane 1 has two bands, one between 2000 and 1600 and one just below 1400. Lane 2 has four bands with one just below 3000, one midway between 1400 and 1000 but slightly closer to 1400, a thick

band that may represent two bands just above 800, and a light band at about one-eighth the height of the gel. Lane 3 has seven bands with two bands evenly spaced between 2000 and 1600, a thick band that may represent two adjacent bands just below 1000, a band just above 800, two bands at about one-third the height of the gel between 500 and 100 but both above the midpoint between those, and one band just above the bottom band in lane 2. All data is approximate.

Return to Figure 38.4 A gel

Extended description for: Figure 38.5 A deoxynucleotide and a dideoxynucleotide

Part a shows the structure of a deoxynucleotide against a background with a triangular cutout at the top and a triangular protrusion

at the bottom. A five-membered ring has O at the top vertex, C 1 prime at the upper right vertex bonded to a base above and H below, C 2 prime at the lower right vertex bonded to H above and below, C 3 prime at the lower left vertex bonded to H above and to O below that is further bonded, C 4 prime at the upper left vertex bonded to H below and to C 5 prime above, and C 5 prime bonded to 2 H and to O bonded to P double bonded to O to the right, bonded to O above, and bonded to O minus to the left. The O bonded to C 3 prime is further bonded to P double bonded to O to the right, bonded to O minus to the left, and bonded to O below further bonded to C 5 prime bonded to 2 H

and to C 4 prime at the upper left vertex of a second five-membered ring. This ring is similar to the first except that C 3 prime is bonded to H above and highlighted O H below.

Part b shows the structure of a dideoxynucleotide. It resembles the top half of the structure in part a and is depicted against a background with a triangular cutout above and a flat bottom. The difference between this ring and the ring at the top in part a is that C 3 prime is bonded to H above and to highlighted H below.

Return to Figure 38.5 A deoxynucleotide and a dideoxynucleotide

Extended description for: Figure 38.6 Chain termination

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

On the left, a template strand runs from a triangular protrusion labeled 3 prime at the top to a triangular cutout

labeled 5 prime at its bottom. From top to bottom, the sequence is 3 prime T G A T G G C T C A 5 prime. A short daughter strand at the top right forms hydrogen bonds with the top part of the template strand. This strand has a triangular cutout at its 5 prime end at the top and ends at a flat 3 prime end below. Its sequence is 5 prime A C T A C purple highlighted C 3 prime with the purple highlighted C labeled, dideoxynucleotide terminator with fluorescent tag.

Return to Figure 38.6 Chain termination

Extended description for: Figure 38.7 Sanger sequencing

On the lower left is a strand of D N A with a triangular protrusion at its 3 prime end on top and a triangular

cutout at its 5 prime end below. The strand has ten question marks from top to bottom. A graph above has multicolored peaks with very tall peaks above small ups and downs of multicolored lines below. From left to right, the peaks are positioned above pieces of D N A that start at the 5 prime end of a strand complementary to the strand on the left and that increase one base at a time in length from left to right. The first peak is green and above a strand of 5 prime green A; the second peak is purple and is above a strand of 5 prime question mark purple C; the third peak is red and is above a strand of 5 prime question mark question mark red T; the fourth peak is green and is

above a strand of 5 prime 3 question marks and then green A; the fifth peak is purple and large, with a small dip in the middle between two strands below with the left-hand strand having 5 prime 4 question marks and then purple C and the right-hand strand having 5 prime 5 question marks and then purple C; the seventh peak is blue and is above a strand of 5 prime 6 question marks blue G; the eighth peak is green and is above a strand of 5 prime 7 question marks green A; the ninth peak is blue and is above a strand of 5 prime 8 question marks blue G; and the tenth peak is red and is above a strand of 5 prime 9 question marks red T. An arrow points right to a complete

strand of 5 prime A C T A C C G A G T 3 prime, color-coded to match the graph.

Return to Figure 38.7 Sanger sequencing

Extended description for: A figure shows an example of the overhang that can be produced when D N A is cut by the type of restriction enzyme that produces overhangs

Two fragments of D N A are depicted with a plus symbol between them. They can be added together to form two complementary strands because they have complementary unpaired

bases. The left-hand piece has a top strand beginning at its 5 prime end on the left with G, then has an arrow pointing down to the right of G, then is labeled 3 prime at the far end. The bottom strand begins at its 3 prime end on the left and has a sequence of C T T A A and then an arrow pointing upward to the right of A before its 5 prime end. The right-hand piece has a top strand that begins at its 5 prime end on the left with an arrow pointing downward and then A A T T C before reaching its 3 prime end. Its bottom strand begins at its 3 prime end on the left with a large space, then has an arrow pointing upward before G just before its 5 prime end.

Return to A figure shows an example of the overhang that can be produced when D N A is cut by the type of restriction enzyme that produces overhangs

Extended description for: Figure 38.8 Examples of restriction enzymes

At the upper left, Bam H 1 has a top strand of 5 prime G G A T C C 3 prime with an arrow pointing down between G and G and a bottom strand of 3 prime C C T A G G 5 prime with an arrow pointing up between G and G.

At the upper right, Hind 3 has a top strand of 5 prime A A G C T T 3 prime with an arrow pointing down between A and A and a bottom strand of 3 prime T T C G A A 5 prime with an arrow pointing up between A and A. At the middle left, K p n 1 has a top strand of 5 prime G G T A C C 3 prime with an arrow pointing down between G and G and a bottom strand of 3 prime C C A T G G 5 prime with an arrow pointing up between G and G. At the middle right, S s t 1 has a top strand of 5 prime G A G C T C 3 prime with an arrow pointing down between G and A and a bottom strand of 3 prime C T C G A G 5 prime with an arrow pointing up between A and G. At the lower left, H p a 1 has a top

strand of 5 prime G T T A A C 3 prime with an arrow pointing down between G and T and a bottom strand of 3 prime C A A T T G 5 prime with an arrow pointing up between T and G. At the lower right, S m a 1 has a top strand of 5 prime C C C G G G 3 prime with an arrow pointing down between the first and second C bases and a bottom strand of 3 prime G G G C C C 5 prime with an arrow pointing down at the middle C base.

Return to Figure 38.8 Examples of restriction enzymes

Extended description for: Figure 38.9 Cutting by restriction enzymes

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows a circular D N A plasmid that has six Eco R 1 cleavage sites. Clockwise from the upper right, the distances between successive sites are 5.5 k b, 4 k b, 7.5 k b, 5 k b, 6 k b, and

22 k b. Lines point to two of the adjacent cleavage sites and is accompanied by text reading, Each tick mark represents a cleavage site for Eco R 1.

Part b shows a vertical rectangular electrophoresis gel inside a box with a horizontal bar near the top attached to a disk labeled minus with a wire extending from it and a horizontal bar near the bottom attached to a disk labeled minus with a wire extending from it. There are eight small square cutouts across the top end of the gel. In the vertical lane extending down from the right-hand cutout, there are six small purple bars. The first bar is labeled 22 k b p and is just below the

cutout. The second bar is labeled 7. 5 k b p and is approximately halfway down the gel. Just over one-third of the way up the gel, there are two bars close together with the top bar labeled 6 k b p and the bottom bar labeled 5.5 k b p. At about one-quarter of the height of the gel, a small bar is labeled 5 k b p. Near the bottom of the gel, a bar is labeled 4 k b p. All data are approximate. Accompanying text reads, Gel electrophoresis separates the resulting D N A fragments according to their size in k b p, or thousands of base pairs.

Return to Figure 38.9 Cutting by restriction enzymes

Extended description for: Figure 38.10 Recombinant DNA

Morris, et al., *Biology for the AP® Course*, 1e. © 2022 BFW High School Publishers

At the top of the illustration, a horizontal X-shaped chromosome is

labeled Donor D N A (chromosome) and has two vertical structures encircling its lower left arm. Each structure almost encircles the chromosome, and these represent restriction enzymes. To the right, a circle labeled Vector D N A (plasmid) has a similar structure on its lower right side, showing that it is being cut by the same restriction enzyme. Text above reads, Donor D N A and vector D N A are both cut with the same enzyme, in this case Eco R 1. An arrow points down from the donor D N A to show a piece of double-stranded D N A with overhanging ends. A close-up shows that the left end of the chromosome has a longer bottom strand of A A T T C and a

short top strand of a single G above the C. The right side has a longer top strand of C T T A A with a short bottom strand of a single G beneath the C. An arrow pointing down from the vector D N A shows that the circle has been cut open to produce two similar piece of D N A. It has the same two ends, just with a curved appearance as they are part of a circle. Arrows show the overhanging ends from the donor D N A and the vector D N A coming together to form a circle with a piece of donor D N A fitted neatly into the opening provided by the matching overlapping ends. There are D N A ligase enzymes on the right and left of each strand being joined, with two

enzymes on the inner strand of D N A and two on the outer strand of D N A. The circular D N A with both donor and vector D N A is labeled, recombinant D N A. Accompanying text reads, The resulting fragments are mixed together and joined by D N A ligase. An arrow points down to show that the recombinant molecule is added to a bacterial cell that contains a chromosome labeled bacterial D N A. This produces a bacterial cell with a bacterial chromosome and a recombinant chromosome. Accompanying text reads, The recombinant D N A molecule is introduced into a bacterial cell by transformation. An arrow points down to show that the

cell replicates to produce eight similar cells. Text below reads, As the bacterial D N A replicates and divides, the recombinant D N A is also replicated and transferred to the daughter cells. The bacteria produce the protein encoded by the donor D N A.

Return to Figure 38.10 Recombinant DNA

Extended description for: Figure 38.12 CRISPR

On the left, a horizontal oval is positioned above a roughly circular structure, and the entire structure is labeled Cas 9 protein. A vertical piece of R N A runs up just to the left of

midline of the circular piece of D N A and to the center of the oval, then bends left to form a loop that extends just to the edge of the oval before curving back and then curving up out of the protein about one-quarter of the way across before curving down slightly. The vertical piece of D N A is labeled “region complementary to target D N A” and the curved hook above the oval is labeled “guide R N A.” Text below reads, Guide R N A combines with the Cas 9 protein. An arrow points right to show the same structure with double-stranded target D N A running vertically through the middle. The D N A is double stranded above and below the protein, but it separates to the left and right within

the protein, and its left side bonds to the vertical piece of R N A. The D N A is cut on each side right where the oval and circle of Cas 9 meet. Text below reads, Guide R N A brings Cas 9 to the target D N A and the target is cut.

Return to Figure 38.12 CRISPR

Extended description for: A figure shows four electrophoresis gels labeled a through d on which D N A has been separated

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

All of the gels are vertical with a downward-pointing arrow along the left side reading, Direction of D N A migration. Each has two small horizontal rectangles along the top row labeled loading wells. The left-hand loading well is in a lane labeled

size ladder and the right-hand loading well is in a lane labeled digested D N A.

Gel A: The size ladder has relatively evenly spaced bands in the size ladder lane. From top to bottom, these are labeled 500 b p, 1000 b p, 1500 b p, 2000 b p, 2500 b p, and 3000 b p. The digested D N A land has four bands with one located about halfway between the 500 and 1000 b p size ladder bands, one between the 1000 and 1500 b p bands that is slightly closer to the 1500 b p band, one between the 1500 and 2000 b p bands that is slightly closer to the 1500 b p band, and one about halfway between the 2000 and 2500 b p bands.

Gel B: The size ladder has relatively evenly spaced bands in the size ladder lane that get slightly farther apart toward the bottom of the gel. From top to bottom, these are labeled 1000 b p, 2000 b p, 3000 b p, 4000 b p, 5000 b p, 6000 b p, and 7000 b p. The digested D N A lane has four bands with one located about halfway between the 2000 and 3000 b p size ladder bands but slightly closer to the 2000 band, one located between the 3000 and 4000 size ladder bands but slightly closer to the 3000 band, one located halfway between the 4000 and 5000 b p bands, and one located halfway between the 6000 and 7000 b p bands.

Gel C: The size ladder has relatively evenly spaced bands in the size ladder lane. From top to bottom, these are labeled 3000 b p, 2500 b p, 2000 b p, 1500 b p, 1000 b p, and 500 b p. The digested D N A land has four bands with one located about halfway between the 2500 and 2000 b p size ladder bands, one between the 2000 and 1500 b p bands, one between the 1500 and 1000 b p bands that is slightly closer to the 1500 b p band, and one about halfway between the 1000 and 500 b p bands.

Gel D: The size ladder has relatively evenly spaced bands in the size ladder lane that get slightly farther apart toward the bottom of the gel. From

top to bottom, these are labeled 7000 b p, 6000 b p, 5000 b p, 4000 b p, 3000 b p, 2000 b p, and 1000 b p. The digested D N A land has four bands with one located just above the 6000 b p size ladder band, one about halfway between the 5000 and 4000 size ladder bands but slightly closer to the 5000 band, one between about halfway between the 4000 and 3000 b p size ladder bands but slightly closer to the 3000 band, and one located between the 3000 and 2000 size ladder bands but slightly closer to the 2000 band. All data are approximate.

Return to A figure shows four electrophoresis gels labeled a through d on which D N A has been separated

Extended description for: A horizontal electrophoresis gel shows band patterns from hair at a crime scene and four suspects

The gel has a downward-pointing arrow along the left side reading, Direction of D N A migration. A row

of five small horizontal rectangles along the top row is labeled loading wells. From left to right, these are labeled hair at crime scene, suspect 1, suspect 2, suspect 3, and suspect 4. The data in the lanes are as follows, presented from top to bottom.

Hair at crime scene: band at seven-eighths the height of the gel, three-quarters the height of the gel, one-quarter the height of the gel, and one-eighth the height of the gel.

Suspect 1: band at just below seven-eighths the height of the gel, three-quarters the height of the gel, one-quarter the height of the gel, and just above one-eighth the height of the

gel.

Suspect 2: band at seven-eighths the height of the gel, three-quarters the height of the gel, one-quarter the height of the gel, and one-eighth the height of the gel.

Suspect 3: bands at just below seven-eighths the height of the gel, just above one-half the height of the gel, just below one-half the height of the gel, and just above one-eighth the height of the gel.

Suspect 4: band at seven-eighths the height of the gel, just above one-half the height of the gel, one-quarter the height of the gel, and just above one-eighth the height of the gel. All data is

approximate.

Return to A horizontal electrophoresis gel shows band patterns from hair at a crime scene and four suspects

Extended description for: A horizontal electrophoresis gel shows band patterns from a mother bird and six chicks

The gel has a downward-pointing arrow along the left side reading, Direction of D N A migration. A row of seven small horizontal rectangles along the top row is labeled loading

wells. From left to right, these are labeled mother bird and chicks 1 through 6. The data in the lanes are as follows, presented from top to bottom. Mother bird: bands at just above the midpoint and just below the midpoint of the gel; chick 1: band at just above the midpoint and at the midpoint of the gel; chick 2: bands at just above the midpoint and at one-quarter of the height of the gel; chick 3: bands at the midpoint and just below the midpoint of the gel; chick 4: bands at three-quarters the height of the gel and just below the midpoint of the gel; chick 5: bands at just above the midpoint and at very slightly below the midpoint; and chick 6: bands at just below the midpoint and

at one-quarter of the height of the gel. All data are approximate.

Return to A horizontal electrophoresis gel shows band patterns from a mother bird and six chicks

Extended description for: Figure 39.2 Viral shapes

Part a is labeled head-and-tail. A micrograph shows a hexagonal structure with a cylinder below linked to thready protrusions that extend down to all sides. Below, an illustration of a T 4 bacteriophage shows that it has a hexagonal head

containing a circular double helix and a long cylindrical tail with tail fibers at the end, which are pieces that extend out and then down.

Part b is labeled helical capsid. A micrograph shows rod-like structures. Below, an illustration shows a cylinder made of many small subunits in diagonal lines along its sides and labeled tobacco mosaic virus. A coil of red extends up from its top.

Part c is labeled icosahedral capsid. A geometric structure is almost round with many dots along its surface. Below, an illustration of an adenovirus shows a twenty-sided

geometric structure with many spheres along flattened triangular sides and cut away to show a coil of double helix inside.

Part d is labeled enveloped with spikes. Four round structures have many protrusions around their circumferences. Below, an illustration of a coronavirus shows a membranous sphere with a single coiled structure inside, cylinders extending across the membrane to knobby structures at their outer ends, and various oval proteins in the membrane.

Return to Figure 39.2 Viral shapes

Extended description for: Figure 39.4 Lytic and lysogenic pathways

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows the first stage, infection, as a single mature lambda bacteriophage attached to a bacterial cell with a plasmid. The phage has a hexagonal head with a cylinder that extends down to strands that attach it to the cell. The second stage is circulation in which the viral D N A is inside the bacterium and has formed a circle. Two arrows from the second stage point to the lytic pathway and lysogenic pathway. In the lytic pathway, the bacterial cell has viral particles and fragmented bacterial D N A. An arrow points down to show the bacterial cell bursting to release the viruses. The illustration for the lysogenic pathway shows the fusion of the viral and bacterial D N A to

form a single, circular chromosome.

Return to Figure 39.4 Lytic and lysogenic pathways

Extended description for: Figure 39.5 Pandemics in history

The horizontal axis of the graph is labeled year and ranges from before 1300 to 2000. The vertical axis of the graph is labeled number of deaths (millions) and ranges from 0 to 200, in increments of 50. The data in the graph are as follows, depicted using

bars by date: Bubonic plague (Black Death) 1347 to 1351, 200 million deaths; Smallpox 1520, 55 million deaths; Seventeenth-century Great Plagues, 1660, 15 million deaths; Flu pandemic (Spanish flu) 1918 to 1919, 50 million deaths; H I V slash AIDs 1981 to present, 35 million deaths; and COVID-19 2020 to present, 8 million deaths. All data are approximate.

Return to Figure 39.5 Pandemics in history

Extended description for: Figure 39.6 HIV infection

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration shows H I V with a central structure that is roughly triangular but with rounded corners and that contains two wavy lines. This is surrounded by an outer membranous envelope with cylindrical structures extending

across it to ovals outside of the virus labeled C D 4. One of the C D 4 ovals is attached to the end of a chain of four roughly round to hexagonal structures labeled C D 4 receptor that has a tail extending through the membrane into the cytoplasm. A wavy C C R 5 co-receptor bends up and down across the membrane several times before meeting C D 4 next to the C D 4 receptor.

Return to Figure 39.6 HIV infection

Extended description for: Figure 39.9 Viruses in the oceans

The left-hand chart is labeled number of individuals and shows the following approximate data: viruses, 94 percent; bacteria slash archaea, 5 percent; and single-celled eukaryotes, 1 percent. The right-hand chart is labeled biomass and shows the

following approximate data: bacteria slash archaea, 92 percent; viruses, 5 percent; and single-celled eukaryotes, 3 percent.

Return to Figure 39.9 Viruses in the oceans

Extended description for: Visual Synthesis 6.2 Viruses

The illustration on the top left shows six types of viruses with their genetic material. Text reads: “Diversity: Viruses come in many different shapes and viral genomes include a diverse array of types and structures of nucleic acids.” The viruses from

left to right are as follows: The bacteriophage lambda is bolded and labeled (D N A). It has a hexagonal top with a circle of genetic material inside, a long cylindrical part, and then five short pieces that extend out and then down for attachment. A close-up of its genome shows a circular double helix. The adenovirus has a geometric shape with multiple flattened sides and with rods extending outward to spheres, is labeled (D N A), and has a close-up showing a wavy double helix. The picobirnavirus has a geometric shape that is smooth, is labeled (R N A), and has a close-up showing a wavy double helix. The rabies virus resembles a rectangle with a smooth, slightly

pointed top, is labeled (R N A), and has a close-up showing a single vertical coil. The tobacco mosaic virus has a cylindrical shape made of many small pieces, is labeled (R N A), and has a close-up showing a single vertical coil. Finally, the H I V is bolded, is labeled (R N A), and is spherical with protrusions that have short cylindrical bases that branch into ovals. A close-up shows two single wavy strands. A dark, similar virus is to the right.

To the right, the illustration shows a boy with his intestines illustrated over his clothing. An arrow from the intestinal wall shows an enlarged bacterial cell with a mature lambda

phage. Replicated viral components and fragmented bacterial D N A undergo lysis to yield mature assembled viruses that are released outside the cell. Another illustration shows a cell that undergoes lysogeny in which the viral D N A has integrated into the bacterial D N A. Text reads: “Transcriptional regulation: When bacterial cells are grown in favorable conditions, bacterial proteases degrade a key viral protein that would otherwise prevent transcription of other viral genes, leading to production of new viruses and bursting of the bacterial cell (lysis). When bacterial cells are grown in poor conditions, the viral protein accumulates and genes are

transcribed that allow the viral genome to remain integrated in host genome (lysogeny).”

An arrow from a blood vessel on a boy's arm is enlarged, and an arrow points to a close-up of a cell being infected with H I V. To the left, an intact sphere with many small protrusions is depicted next to a similar sphere cut away to show a roughly triangular structure inside containing coils of genetic material. This is labeled human immunodeficiency virus (H I V), and the protrusions are labeled g p 120. One of the protrusions is joined to a strand of four spheres labeled C D 4 with a tail that extends across the

adjacent cell membrane. Text above reads, Replication cycle: Viruses are not considered living organisms because they cannot replicate on their own and absolutely require a cell to complete their replication cycle.

Along the cell, another H I V particle is depicted bound to C D 4 and to a co-receptor, which is a strand that winds back and forth across the cell membrane several times. Text reads: “1. Attachment: H I V attaches to proteins on the surface of the cell and fuses with the plasma membrane.” An H I V particle is depicted with its envelope joined to the cell membrane so that the outer part of the virus is

intact but the bottom is open into the cell. An arrow points to show the roughly triangular interior part has opened to release two wavy strands of viral R N A. Accompanying text reads, “2. Entry: The virus enters the cytoplasm.” A strand of red viral R N A is depicted with an enzyme labeled reverse transcriptase forming a blue strand, and an arrow points to a blue double helix labeled viral D N A. An arrow points through a nuclear pore to the host D N A to show that the viral D N A is now integrated into it and visible as a segment that is lighter in color than the rest of the D N A. Two arrows point away to two wavy single red strands. Accompanying text reads, “3. Replication: The virus uses

the cell to transcribe the integrated viral D N A into m R N A which is translated into protein." An arrow points from each red strand out through a nuclear pore to two similar strands from which arrows point to two strands and other viral particles including ovals, rods for the ovals to attach to the membrane, and a reverse transcriptase enzyme. The cell membrane is beginning to protrude around this. To the right, a large protrusion of cell membrane has g p 120 on its outside and contains viral R N A and reverse transcriptase. Accompanying text reads, "4. Assembly: The viral components assemble on their own inside of the cell." An arrow points from the

budding virus to a free virus outside of the cell. Accompanying text reads, “5. Release: In the case of H I V, new viruses bud from an intact cell. Other kinds of viruses can burst (lyse) the cell to exit, while still others incorporate their viral genome into that of the host, but are replicated and released at a later time.”

A spherical T cell is visible between mitochondria near rough endoplasmic reticulum near the nucleus just to the right of the place where the virus is emerging from the cell. Accompanying text reads, “Effects: Viruses use the resources of the cell to replicate. They can kill the cell they infect, leading to disease or

death, or cause the cell to divide uncontrollably, leading to cancer. In some cases, they can transfer pieces of D N A from one cell to another. Evolution: The host range and effects of a virus can change because of mutation and recombination. Viruses with segmented genomes can sometimes exchange whole segments. R N A viruses, like H I V and influenza, evolve rapidly because of the high mutation rate of their genomes."

An illustration on the top left shows a sparrow, a dog, and a plant. Text reads: Host range. A given virus can only infect some organisms and types of cell, determined by specific

interactions of viral proteins with cell-surface host proteins. The figure shows how each organism has differently shaped receptors on its cell membranes.

Return to Visual Synthesis 6.2 Viruses

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The table has columns across the top labeled first position (5 prime end),

second position, and third position (3 prime end). There are four rows in the first column. From top to bottom, they are U, C, A, and G. The subcolumns under the second position are U, C, A, and G. There are four rows under the third position that each have the same four nucleotides listed vertically: U, C, A, and G. The data in the rows are as follows.

Row 1 column 1: U U U gives P h e; U U C gives P h e; U U A gives L e u; U U G gives L e u. Row 1 column 2: U C U gives S e r; U C C gives S e r; U C A gives S e r; U C G gives S e r. Row 1 column 3: U A U gives T y r; U A C gives T y r; U A A gives Stop; U A G

gives Stop. Row 1 column 4: U G U gives C y s; U G C gives C y s; U G A gives Stop; U G G gives T r p.

Row 2 column 1: C C U gives L e u; C U C gives L e u; C U A gives L e u; C U G gives L e u. Row 2 column 2: C C U gives P r o; C C C gives P r o; C C A gives P r o; C C G gives P r o. Row 2 column 3: C A U gives H i s; C A C gives H i s; C A A gives G l n; C A G gives G l n. Row 2 column 4: C G U gives A r g; C G C gives A r g; C G A gives A r g; C G G gives A r g.

Row 3 column 1: A U U gives I l e; A U C gives I l e; A U A gives I l e; A U G gives M e t/Start. Row 3 column 2: A C U gives T h r; A C C gives T h r; A C A

gives T h r; A C G gives T h r. Row 3 column 3: A A U gives A s n; A A C gives A s n; A A A gives L y s; A A G gives L y s. Row 3 column 4: A G U gives S e r; A G C gives S e r; A G A gives A r g; A G G gives A r g.

Row 4 column 1: G G U gives V a l; G U C gives V a l; G U A gives V a l; G U G gives V a l. Row 4 column 2: G C U gives A l a; G C C gives A l a; G C A gives A l a; G C G gives A l a. Row 4 column 3: G A U gives A s p; G A C gives A s p; G A A gives G l u; G A G gives G l u. Row 4 column 4: G G U gives G l y; G G C gives G l y; G G A gives G l y; G G G gives G l y.

acids specified by the genetic code

Extended description for: A figure shows a piece of a gene with exons and introns

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The gene is a horizontal line with three boxes representing exons. The first box is labeled exon 1, 661 b p and is beneath an arrow pointing right labeled primer 1. To its right, an arrow points to the line accompanied by text reading, intron 1, 725 b p. The

next box is similar in size and is labeled exon 2, 650 b p. To its right, an arrow points to the line accompanied by text reading, intron 2, 416 b p. The next box is larger and is labeled exon 2, 1302. Above its right end, there is an arrow pointing left labeled primer 2.

Return to A figure shows a piece of a gene with exons and introns

Extended description for: A figure shows four electrophoresis gels labeled a through d. On each gel, a size standard is run in one lane and a P C R product is run in another

All of the gels are vertical with a downward-pointing arrow along the left side reading, Direction of D N A migration. Each has two small horizontal rectangles along the top row labeled loading wells. The left-hand loading well is in a lane labeled

size standard and the right-hand loading well is in a lane labeled P C R product.

Gel A: The size ladder has relatively evenly spaced bands in the size ladder lane. From top to bottom, these are labeled 5000 b p, 4000 b p, 3000 b p, 2000 b p, 1000 b p, and 500 b p. The P C R product is between 4000 and 3000 b p but slightly closer to 4000.

Gel B: The size ladder has relatively evenly spaced bands in the size ladder lane. From top to bottom, these are labeled 5000 b p, 4000 b p, 3000 b p, 2000 b p, 1000 b p, and 500 b p. The P C R product is between 3000 and 2000 b p but slightly closer to 3000.

Gel C: The size ladder has relatively evenly spaced bands in the size ladder lane. From top to bottom, these are labeled 500 b p, 1000 b p, 2000 b p, 3000 b p, 4000 b p, and 5000 b p. The P C R product is between 3000 and 4000 b p but slightly closer to 4000.

Gel D: The size ladder has relatively evenly spaced bands in the size ladder lane. From top to bottom, these are labeled 500 b p, 1000 b p, 2000 b p, 3000 b p, 4000 b p, and 5000 b p. The P C R product is between 2000 and 3000 b p but slightly closer to 3000. All data are approximate.

Return to A figure shows four electrophoresis gels labeled a through

d. On each gel, a size standard is run in one lane and a P C R product is run in another

Extended description for: A figure shows interactions that take place in high blood sugar versus low blood sugar conditions

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The top part of the illustration is labeled high blood sugar. A curved piece of cell membrane contains a Y-shaped insulin receptor with its fork outside of the cell. A triangle labeled

insulin is depicted with an arrow pointing into the fork. An arrow points from the part of the receptor inside the cell to a small rectangle labeled A k t, from which an arrow points to show A k t attached to the upper right of a sphere labeled F O X O. The nucleus is nearby with a horizontal double helix of D N A inside.

The bottom part of the illustration is labeled low blood sugar. The insulin receptor is present, but there is no insulin. A k t is present. The sphere labeled F O X O is not bound to A k t, and an arrow points from F O X O to a similar sphere labeled F O X O bound to the D N A in the nucleus. To the

right, a short vertical line extends up to an arrow pointing right beneath text reading, gluconeogenesis genes.

Return to A figure shows interactions that take place in high blood sugar versus low blood sugar conditions

Extended description for: Two graphs compare bacterial abundance with and without the presence of a phage for both wildtype and mutant bacteria

The left-hand graph is labeled no phage added. The horizontal axis is

labeled time (hours) and ranges from 0 to 18, in increments of 3. The vertical axis is labeled bacterial abundance and ranges from 10 squared to 10 superscript 8, in increments of plus 2 to the exponent. A key indicates that a straight line represents the wildtype bacteria and a dashed line represents mutant bacteria. Both curves begin just before 0 at 10 superscript 4 on the vertical axis. The solid line rises gradually more rapidly until it levels off at 12 hours and 10 superscript 7, after which it runs horizontally to the right end of the graph. The dashed line rises more slowly and levels off at 12 hours at 10 superscript 5.5, after which it runs horizontally to the right

end of the graph.

The right-hand graph is similar but is labeled phage added. The lines begin at the same place, but the solid line decreases slowly and then rapidly to reach the horizontal axis at 6 hours and run along the horizontal axis to the right end of the graph while the dashed line increases to 15 hours at 10 superscript 8 and then runs horizontally to the right end of the graph.

Return to Two graphs compare bacterial abundance with and without the presence of a phage for both wildtype and mutant bacteria

Extended description for: Figure 40.3 Vertebrate body plan

Photo: Stockbroker xtra/AGE Fotostock
Morris, et al., *Biology for the AP* Course*, 1e,
© 2022 BFW High School Publishers

The anterior has a narrow mouth with two whiskers extending to the left. The area where the whiskers attach to the head is dark, but most of the fish is translucent with small spots. The fish has a large eye at the base of the narrow mouth area. A line pointing to the eye is accompanied by text reading, Well-developed brain

and eyes. Just below the eye, a thin line separating a narrow pale area into two halves is labeled, jaws. There is a dark, rectangular to oval region behind the eye and extending up to it. This is labeled cranium and joins a dark region that extends left and down below a horizontal line that extends across the length of the body, the vertebral column. A fin is attached on each side near the front of the dark region and is labeled, paired fins. A dark, segmented line with clear regions above and below extends from the cranium to the beginning of the tail, and the segments in it are labeled vertebrae. Long, thin ribs extend above and below the vertebrae. There is a pale

tail at the right end of the fish with narrow upper and lower halves.

Return to Figure 40.3 Vertebrate body plan

Extended description for: Figure 40.4 Evolutionary relationships among primates

Part b shows a phylogenetic tree with a right-pointing arrow labeled time below. The tree begins with a short horizontal line labeled root on the left. This line meets a short perpendicular line that splits into two

horizontal lines. The top horizontal line extends to text at the far right that reads, Lemurs. The bottom line is short and meets a perpendicular line that splits into a long upper horizontal line that extends to text at the far right that reads, Tarsiers; and a short horizontal line below that meets a perpendicular line. This perpendicular line splits to a long horizontal line above that ends at New World monkeys at the far right and at a short perpendicular line at the lower right. The point where the horizontal line meets the perpendicular line is encircled and labeled, “Nodes indicate a common ancestor.” The perpendicular line meets a top horizontal line that

extends to Old world monkeys at the far right and to a short perpendicular line at the lower right. The place where the horizontal and perpendicular lines meet is circled and a line leads to the same text reading, “Nodes indicate a common ancestor.” The short perpendicular line meets a long horizontal line above that extends right to Gibbons at the far right and a short horizontal line below that meets a short perpendicular line that meets a long horizontal line to Orangutans at the far right and a short horizontal line below. The short horizontal line meets a perpendicular line above that meets a horizontal line above that extends to Gorillas at the far right and

that has a highlighted downward portion that meets a short highlighted horizontal line that meets a short highlighted perpendicular line that has upper and lower highlighted lines to the far right. The top line extends to Chimpanzees and the bottom line extends to Humans.

Return to Figure 40.4 Evolutionary relationships among primates

Extended description for: Figure 40.5 The tree of life

The tree begins at a root at the bottom center. Text below reads, Time runs from the root to the branches. Just over one-third of the way up, the tree branches to a blue part on the left and a red part on the right. The blue part, labeled Bacteria, runs straight, then

branches to many lines that branch further to form a complex array of lines extending to the upper right. Accompanying text reads, Most of life's diversity is microbial. The right-hand branch runs straight to about the level that the blue branch diversifies, at just over half the height of the tree, and forms five major branches that split into many smaller branches that extend outward and are labeled Archaea. The very end of the main red branch continues beyond these and becomes green, where it runs straight for a short distance and then branches to form groups of Eukaryotes. Accompanying text reads, All plants and animals lie on branches within the Eukaryotes. The

overall surface of the tree is relatively rounded and smooth across the sides and tops.

Return to Figure 40.5 The tree of life

Extended description for: An illustration compares ancestral bacteria that have been frozen and then grown versus bacteria that have been grown in a medium with limiting amounts of glucose

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Two Erlenmeyer flasks are each filled to approximately one-third with liquid. The top flask is labeled ancestral and contains clear liquid. The bottom flask is labeled descendant and contains red liquid. Arrows extend from both flasks to a new flask with liquid that is intermediate in color. The arrows from the original flasks to the new flask are mixed in a 1 to 1 ratio, as indicated by text between the arrows reading 1 to 1. The new flask is beneath text reading, “t equals 0.” Text above reads, “At the first time point (t equals 0), the pink color of the flask contents shows that there are similar numbers of ancestral and descendant bacteria. The ratio is 1 to

1.” A photo below the flask shows a quarter of a Petri dish that contains approximately equal numbers of small pink circles labeled ancestral and red circles labeled descendant. There circles represent bacterial colonies. An arrow points from the flask at t equals 0 to a flask at t equals 1 that contains red liquid similar to that in the original flask labeled descendant. Text above reads, “At the second time point (t equals 1), the redder color of the flask contents indicates that there are greater numbers of descendant bacteria and fewer ancestral bacteria. The ratio is no longer 1 to 1.” A photo below shows a quarter of a Petri dish that contains many more red dots than

pink dots representing bacterial colonies.

Return to An illustration compares ancestral bacteria that have been frozen and then grown versus bacteria that have been grown in a medium with limiting amounts of glucose

Extended description for: A graph plots growth of descendant strains relative to ancestral strains by generation to demonstrate evolution between two strains of bacteria

The horizontal axis is labeled, Generation. The vertical axis is labeled, Growth of descendant strains

relative to ancestral strands. A curve begins at the origin and rises rapidly before slowing to form a curve that bends just before one-quarter of the way across the graph at three-quarters of the height of the graph. The curve then runs increasing slightly above the horizontal axis to end at the right end of the horizontal axis near the top of the vertical axis. Text reads, Descendant strains grew more rapidly than ancestral strains at each generation.

Return to A graph plots growth of descendant strains relative to ancestral strains by generation to demonstrate evolution between two strains of bacteria

Extended description for: Figure 41.5 A desert plant adapted for a dry climate

Photo: Charles Harker/Getty Images

There is low vegetation on much of the surrounding ground with some other saguaros and a cactus in the foreground that has disk-shaped leaves and bright flowers.

Return to Figure 41.5 A desert plant adapted for a dry climate

Extended description for: Figure 41.6 Convergent evolution

Photos top: Chase Dekker Wild Life Images/Getty Images; bottom: ullstein bild/Getty Images

Both animals are very streamlined

and smooth with a triangular dorsal fin extending from their backs. Each has fins to the left and right at the front of the body, although the fins differ. Both are darker on top and lighter on the bottom. These features represent convergent evolution. The dolphin has a horizontal tail and the shark has a vertical tail. The dolphin has a narrow, protruding nose with a rounded forehead and the shark has a pointed head with a shorter mouth below.

Return to Figure 41.6 Convergent evolution

Extended description for: Figure 41.7 Stabilizing selection

The horizontal axis is labeled birth weight (kilograms) and ranges from 0 to 6 in increments of 1. The left vertical axis is labeled percent of population with given birth weight and ranges from 0 to 20 in increments of 5. The right vertical axis is labeled

percent of babies at a given birth weight who die and ranges from 0 to 100 in varying increments (2, 5, 10, 20, 50, and 100). A curve representing the percentage of the population with a given birth weight begins at (0.5, 0) and increases to (0.1, 1), then decreases to (1, 0), then increases in a stepwise fashion to peak at (2, 20) and run horizontally to (3.2, 20) before decreasing in a stepwise fashion to end at (4.5, 0). Overall, this forms an irregular curve that is lower at the extremes with a peak in the center.

Dots representing the percent of babies at a given birth weight follows an inverse pattern. They are high at the extremes and reach a minimum

in the middle beneath the peak of the blue curve, then rise again. There are points at (1.25, 74), (1.45, 49.5), (1.75, 24.5), (2, 21), (2.2, 7.6), (2.4, 6), (2.6, 2.2), (3.1. 2.1) (3.6, 2.2), (3.6, 1.8), 3.4, 2.5), (4.0, 2.9), 4.2, 2.6), (4.4, 6), (, 4.7, 7), and (4.8, 15). All data are approximate.

Return to Figure 41.7 Stabilizing selection

Extended description for: Figure 41.8 Directional selection

Photos left: Bill Coster/Alamy Stock; right: Breck P. Kent/AGE Fotostock
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows two photos. On the left, two moths are depicted against a white, brown, and gray speckled background. There is a clearly visible dark moth and a white and black

speckled moth that is difficult to see. On the right, similar moths are depicted against a rough gray background. A mostly white moth with black specks is easy to see, and a dark gray moth with pale stripes on its wings is hard to see.

Part b shows a graph. The horizontal axis is labeled, Year and ranges from below 1800 to after 2000, in increments of 50 years. The vertical axis is labeled, Frequency of the dark (Carbonaria) form and ranges from 0.0 to 1.0, in increments of 0.2. A dashed vertical line extending up across the graph from 1956 is labeled, Clean Air Act 1956. A curve begins at (0.0, 1780) and runs horizontally to

(1750, 0.0), then curves steeply upward before leveling off at (1890, 0.90) and running horizontally beginning at (1915, 0.95). At (1960, 0.90), the line begins to curve down slightly, and then it bends to descend rapidly beginning at (1975, 0.90). The curve ends at (1010, 0.05). All data are approximate.

Return to Figure 41.8 Directional selection

Extended description for: Figure 41.9 Disruptive selection

Photo: Rob Oakleaf, Michigan State University, Tree Fruit Entomology Lab
Morris, et al., *Biology for the AP® Course, 1e*, © 2022 BFW High School Publishers

Part a is a photo of a small black fly

sitting on an apple.

Part b is a graph with two curves on it. The horizontal axis is labeled 1991 and ranges from June 15 to October 15, in increments of 15 days. The vertical axis is labeled percent of total larval population infesting fruit on a given date and ranges from 0 to 100, in increments of 25. The first curve, representing larvae feeding on apples, begins at (June 28, 0) and rises to a peak at (August 2, 90) before descending to (September 2, 2) and then leveling off to run horizontally to (September 14, 0). The second curve, labeled larvae feeding on hawthorns, begins at (July 21, 0) and rises to a peak at (August 31, 89) before

descending to (October 1, 3) and then running almost horizontally to end at (October 15, 0). All data are approximate.

Return to Figure 41.9 Disruptive selection

Extended description for: Figure 41.10 Artificial selection

Photos (a)–(c): Richard Bailey/Getty Images; (d): Jose A. Bernat Bacete/Getty Images

Parts a through c show artificially selected breeds. Part a shows a photo of a Pygmy Pouter, which is a black and white pigeon with white feet, white patches, and a white breast. It is

slender apart from a broad breast. Part b shows a photo of an Old Dutch Capuchine, which is an orange-tan and white bird that is mostly orangish white on its thick body and wings with a ruff around its neck. It has a white head, white along the front of its upper legs, white wing tips, and a white tail. Part c shows a Blue Grizzle Frillback, which is a gray bird with a pale head with a yellow eye, a greenish neck with darker gray to blue below, a frilly-looking body with many curved feathers, and black wing tips and tail.

Part d shows a Rock pigeon, which was the ancestor of the other, artificially selected breeds. It has a

gray head with yellowish-orange eye, a green neck, a gray breast, pink feet, white wings with two black bars on the wings above the body before their gray tips extend beyond the body, and a gray tail.

Return to Figure 41.10 Artificial selection

Extended description for: A graph plots percent oil content against generation for two species of corn, one of which was artificially selected for high oil content and the other of which was artificially selected for low oil content

Morris, et al., *Biology for the AP ® Course*, 1e, © 2022 BFW High School Publishers

The horizontal axis is labeled generation and ranges from 0 to 100, in increments of 10. The vertical axis is labeled percent oil content and ranges from 0 to 23, in increments of 1. The first curve, representing the population that underwent selection for high oil content, begins at (0, 4.9) and follows a zigzag path in a basic diagonal pattern to end at (100, 20.5).

The second curve, representing selection for low oil content, begins at (0, 4) and follows a zigzag path that is slightly curved and increasingly horizontal as it descends to meet the horizontal axis at (85, 0). Accompanying text beneath the curve for high oil content reads, The final high oil content level of 20.5, which is approximately four times the starting level at 4.9. All data are approximate.

Return to A graph plots percent oil content against generation for two species of corn, one of which was artificially selected for high oil content and the other of which was artificially selected for low oil content

Extended description for: Four pairs of graphs labeled a through d show pre-selection and post-selection frequencies of a trait

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

All four pairs of graphs show a horizontal axis labeled trait value that ranges from below 2 to 10, in increments of 2; and a vertical axis labeled Frequency in population that ranges from 0 to 100, in increments of

50. All of the pre-selection graphs are identical and show a bell curve that begins at (3, 0), peaks at (6, 52), and ends at (9, 0).

Part a: An arrow points right to the post-selection graph, which begins at (6.1, 0), peaks at (8.5, 60), and ends at (11, 0).

Part b: An arrow points right to the post-selection graph, which begins at (4, 0), peaks at (6, 80), and ends at (11, 0).

Part c: An arrow points right to the post-selection graph, which begins at (3, 0), rises to (4, 48), drops to (5.8, 30), rises to (7.3, 49), and drops to (8.3, 10) before dropping to run

horizontally along the horizontal axis to the right end of the graph.

Part d: An arrow points right to the post-selection graph, which begins at (1.8, 0)), peaks at (3.5, 60), and ends at (5.9, 0).

Return to Four pairs of graphs labeled a through d show pre-selection and post-selection frequencies of a trait

Extended description for: A bar graph plots mean percentage of pure red in feathers for captive versus wild cardinals

The horizontal axis is labeled with two categories, captive and wild. The

vertical axis is labeled mean percentage of pure red in feathers and ranges from 30 to 90, in increments of 10. The bar for captive extends to 51 with a standard deviation extending to 58. The bar for wild extends to 75 with a standard deviation extending to 82. All data are approximate.

Return to A bar graph plots mean percentage of pure red in feathers for captive versus wild cardinals

Extended description for: Figure 42.2 Mutation and recombination

The illustration shows an allele 1 labeled T T T T in generation 1. Arrows point to the lower left and right. The arrow pointing to the lower

left is labeled mutation and produces allele 2, which is C (highlighted) T T T. The arrow pointing to the lower right is labeled no mutation and produces allele 1, which is T T T T. These two products represent generation 2. Accompanying text reads, Mutations create new alleles. Two arrows point down from allele 2 in the second generation. The arrow that points down to the lower left is labeled no mutation and yields allele 2, with C (highlighted) T T T. The arrow that points down to the lower right is labeled mutation and yields allele 3, which is C (highlighted) T G (highlighted) T. Allele 1 in generation 2 has a single arrow pointing down to the lower right labeled no mutation

that yields allele 1, which is T T T T. Generation 3 therefore consists of a copy of allele 2, a copy of allele 3, and a copy of allele 1. Arrows point down from allele 3 and allele 1 in generation 3 to show the two alleles together with allele 3 on top and allele 1 below. Dashed crossed lines extend from between T and G of allele 3 above to between the second and third T nucleotides of allele 1 below. Accompanying text reads, Recombination. An arrow points down to allele 4, which is T T G (highlighted) T. This is generation 4. Accompanying text reads, Recombination shuffles mutations to produce new alleles.

Return to Figure 42.2 Mutation and recombination

Extended description for: Figure 42.3 Mutation rate

The horizontal axis is labeled, Genome size (base pairs) and ranges from below 10 superscript 4 to 10 superscript 10, in logarithmic increments. The vertical axis is

labeled Rate of mutation per nucleotide pair per round of replication and ranges from 10 superscript negative 11 to 10 superscript negative 3, in logarithmic increments. The data in the graph is as follows: D N A viruses are at (10 superscript 3.9, 10 superscript negative 6.1), (10 superscript 4.8, 10 superscript negative 7.2), and (10 superscript 5.2, 10 superscript negative 7.7); R N A viruses and retroviruses are at (10 superscript 4, 10 superscript negative 4.3), (10 superscript 3.7, 10 superscript negative 4.1), (10 superscript negative 3.9, 10 superscript negative 4), (10 superscript 4.2, 10 superscript negative 3.4), and (10 superscript 4.2,

10 superscript negative 4.2); H I V is at (10 superscript 4, 10 superscript negative 4.7); Bacteria are at (10 superscript 6.7, 10 superscript negative 9.2); Yeast is at (10 superscript 7.1, 10 superscript negative 9.8); Bread mold is at 10 superscript 7.6, 10 superscript negative 10.1); Nematode is at (10 superscript negative 8, 10 superscript negative 9.7); Fruit fly is at (10 superscript 8.2, 10 superscript negative 9.3); Mouse is at (19 superscript 9.5, 10 superscript negative 10.8); and Human is at (10 superscript 9.6, 10 superscript negative 9.4). The graph shows that small genome sizes are correlated with high rates of mutation, and vice

versa. All data are approximate.

Return to Figure 42.3 Mutation rate

Extended description for: A figure shows how to carry out replica plating

Agar plate 1 is a round dish with eight round colonies on it. Above, a disk covered in velvet fastened by a band has a cylindrical handle extending from the back. This velvet-covered disk is labeled velvet disk. An arrow

shows that the velvet disk is lowered to fit into agar plate 1. An arrow points right to show the same velvet disk with circles in the exact same relative locations as on agar plate 1. An arrow points down to show that the velvet disk will be lowered onto agar plate 2 to place bacterial colonies in the exact same relative positions as on agar plate 1. Accompanying text reads, The sterile velvet disk picks up and transfers cells to a new plate. An arrow points down accompanied by text reading, Incubation to allow growth of colonies. This yields a plate that looks exactly like agar plate 1 with colonies in the same locations.

Return to A figure shows how to carry

out replica plating

Extended description for: A figure shows how to use replica plating to test the effects of an antibiotic

Morris, et al., *Biology for the AP*® *Course*, 1e, © 2022 BFW High School Publishers

A master plate is an agar plate with eight colonies on it. One colony at the center upper right is highlighted in red. A velvet disk is present above with an arrow to indicate that it is being lowered onto the plate. Text

below reads, Highlighted red colony contains antibiotic-resistant bacteria. An arrow points right to show the velvet disk with bacterial colonies on it, including the highlighted colony, in the same relative positions as on the original master plate. One arrow points down from the velvet disk to an empty agar plate from which a second arrow points downward accompanied by text reading, Incubation to allow growth of colonies. This yields a plate that resembles the master plate. Text below reads, Control: No antibiotic. Additional accompanying text reads, All cells grow on the nonselective medium. A second arrow points from the same velvet disc to a similar blank agar plate at the upper right. An

arrow points downward accompanied by a text reading, Incubation to allow growth of colonies. This yields a plate with a single red highlighted colony in the position of the red highlighted colony of the master plate. Text below reads, Experimental: Antibiotic. Additional accompanying text reads, Only the antibiotic-resistant cells grow on the selective medium; the location of the colony indicates which colony on the nonselective medium contains the antibiotic-resistant cells.

Return to A figure shows how to use replica plating to test the effects of an antibiotic

Extended description for: A figure shows how the Lederbergs grew a culture of antibiotic-resistant bacteria from an antibiotic-resistant colony identified using replica plating

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A master plate is an agar plate with eight colonies, of which one is highlighted and labeled, antibiotic-resistant colony. An arrow points from this highlighted colony into an Erlenmeyer flask that is approximately one-third filled with medium. The liquid in the flask is labeled, pure culture of antibiotic-resistant bacteria. An arrow points

down from the flask to an agar plate containing eleven highlighted colonies. Text below reads, Plate containing antibiotic.

Return to A figure shows how the Lederbergs grew a culture of antibiotic-resistant bacteria from an antibiotic-resistant colony identified using replica plating

Extended description for: Figure 42.4 Common mutations in populations

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a is titled point mutation. A double-stranded piece of D N A is illustrated with small squares

extending into the center from each strand to represent the bases. The top strand has a triangular cutout on the left and a triangular protrusion on the right, and the bottom strand has the reverse. The sequence of bases in the top strand is C C T G A G G A G. The sequence of bases in the bottom strand is G G A C T C C T C. To its right, there is a similar double stranded piece of D N A in which one set of bases is changed and highlighted. The top strand is C C T G A A (highlighted) G A G and the bottom strand is G G A C T T (highlighted) C T C.

Part b is titled duplication and deletion. A chromosome is illustrated

that has a round centromere to the left with a short arm to the left and a long arm to the right. In the middle of the long arm is a highlighted region with a triangular cutout on the left and a triangular protrusion on the right. Arrows point to the lower left and right. The arrow that points to the lower left indicates a similar chromosome in which there are two adjacent copies of the highlighted region; the copies are labeled duplication. The arrow that points to the lower right indicates a similar chromosome in which the highlighted region is missing; this is labeled deletion.

Part c is titled movement of a

transposable element. A horizontal chromosome has a small circular centromere with a small arm to the left and a longer arm to the right. The longer arm has a highlighted bar labeled transposable element with darker bars to its left and right. An arrow points right through a similar vertical bar beneath the word transposition to a differently colored, larger chromosome with a short arm on the left and a long arm on the right. An arrow points downward. The left-hand chromosome is similar, but the bar is missing a line pointing to the place where it had been and is labeled, transposable element excised. To the right, the larger chromosome is depicted with a bar in

its long arm. A line pointing to this bar reads, transposable element inserted.

Return to Figure 42.4 Common mutations in populations

Extended description for: A figure illustrates how gel electrophoresis works and how it can be used to detect genetic variation

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A figure shows a fruit fly (Drosophila melanogaster) with an arrow pointing from it to a mortar and pestle. Accompanying text reads, The fly is ground up. A rectangular electrophoresis gel, labeled gel, is below with eight small rectangular

cutouts at the top labeled wells. Each cutout has a small horizontal rectangle beneath it with an arrow pointing downward. These small horizontal rectangles are labeled, sample from one individual. A circle with a negative symbol in it at the top of the gel by the wells is labeled negative electrode, and a circle with a positive symbol at the bottom of the gel is labeled negative electrode. Accompanying text above the wells reads, Each well of the gel is labeled with a sample from a different individual. An electric current is passed through the gel. The proteins in each sample migrate toward the positive electrode according to their charge and size.

Return to A figure illustrates how gel electrophoresis works and how it can be used to detect genetic variation

Extended description for: An electrophoresis gel contains small rectangular cutouts at the top numbered one through eight that mark eight lanes, each of which contains bands for comparison to determine whether each sample had an S S, F F, or F S genotype

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Text above the gel reads, The gel is stained with a biochemical agent that produces color in the presence of A d h enzyme. Lane 1, beneath well 1, has two pale bands immediately above a dark band one-third of the way down the gel. A line pointing to this dark band reads, S S homozygote. Lane 2 is similar. Lane 3 has a similar set of

three bands, but the bottom one has only a narrow purple band instead of a dark purple band. Just below halfway down the gel, it has a similar set of three bands with a narrow band in the bottom one. Lane 4 has three bands with one at the midpoint, a small space, and then two just below the midpoint aligned with the bottom two from lane 3 to the left. The bottom band has a thick dark band and is labeled, F F homozygote. Lane 5 has a set of three bands like lane 1 with a dark band in the bottom band. Lane 6 has two sets of three bands like lane 3. The bottom band of each set of three, which has a narrow band, is labeled F S heterozygote. Lane 7 has a similar set of bands to

lane 4. Lane 8 has a similar set of bands to lane 1. Text below reads, S S homozygote: lanes 1, 2, 5, 8; F F homozygote: lanes 4, 7; F S heterozygote: lanes 3, 5. All data are approximate.

Return to An electrophoresis gel contains small rectangular cutouts at the top numbered one through eight that mark eight lanes, each of which contains bands for comparison to determine whether each sample had an S S, F F, or F S genotype

Extended description for: A stacked bar graph plots the percentage of fish that are completely plated, partially plated, and unplated against year

The horizontal axis is titled year, and four bars appear at the following labeled increments: 1957, 1968/1969,

1976, and 2005. The vertical axis is titled percentage of fish that are completely plated, partially plated, and unplated and ranges from 0 to 100, in increments of 10. A key indicates colors showing unplated fish, partially plated fish, and completely plated fish. The data in the graph are as follows. Year 1957: 90 percent of fish were unplated and 10 percent were partially plated; Year 1968/1968: 69 percent of fish were unplated, 24 percent were partially plated, and 7 percent were completely plated; Year 1976: 26 percent of fish were unplated: 33 percent of fish were partially plated; and 41 percent of fish were fully plated. Year 2005: 17 percent of fish were unplated, 34

percent of fish were partially plated, and 49 percent of fish were fully plated. All data are approximate.

Return to A stacked bar graph plots the percentage of fish that are completely plated, partially plated, and unplated against year

Extended description for: Two electrophoresis gels compare protein bands for the hemoglobin protein for Atlantic cod from the east coast of Norway versus the west coast of Norway

The top electrophoresis gel is labeled

East Coast of Norway and contains fifteen rectangular wells in a horizontal line across the top. Each land contains one or two protein bands beneath it. All of the bands are in an upper position at approximately the midline of the gel or just below the midline of the gel, referred to as the upper and lower positions, respectively. From left to right, the bands are as follows: well 1: lower band only; well 2: two bands; well 3: 2 bands; well 4: lower band only; well 5: upper band only; well 6: both bands; well 7: both bands; well 8: lower band only; well 9: both bands; well 10 upper band only; well 11: lower band only; well 12: both bands; well 13: lower band only; well 14: lower band

only; and well 15: both bands.

The bottom electrophoresis gel is similar. It is labeled West Coast of Norway. From left to right, the bands are as follows. Well 1: both bands; well 2: lower band only; well 3: upper band only; well 4: upper band only; well 5: both bands; well 6: both bands; well 7: both bands; well 8: upper band only; well 9: upper band only; well 10: lower band only; well 11: lower band only; well 12: upper band only; well 13: both bands; well 14: upper band only; and well 15: upper band only. All data are approximate.

Return to Two electrophoresis gels compare protein bands for the

hemoglobin protein for Atlantic cod from the east coast of Norway versus the west coast of Norway

Extended description for: Figure 43.2 Natural selection

The figure shows three vertical columns with six birds in each, labeled from left to right as

populations 1, 2, and 3. The left-hand column contains birds that are relatively light brown with notable brown marks on their abdomens near the top. The birds get progressively darker from top to bottom. The top two, lightest birds are enclosed in a bracket, and an arrow labeled generations points right to the third bird in the second vertical column of birds labeled population 2. The third bird resembles the top bird of population 1, depicted in column 1, but the birds below are all lighter than their counterparts in column 1 even though they still become progressively darker from top to bottom. A bracket encloses the top two, lightest birds, and an arrow

labeled generations points right to the third bird in the third column.

Return to Figure 43.2 Natural selection

Extended description for: Figure 43.4 Genetic drift

On the left, a vertical column of six birds is labeled population 1. The top bird is light brown with clearly visible darker spots and streaks, and the

birds get progressively darker from top to bottom, with the bottom bird being entirely dark. An arrow labeled random loss of part of the population points from between the third and fourth birds from the top of the left-hand column to show the same two birds forming a short vertical column with no other birds that is labeled population 2. An arrow points right from these two birds to a vertical column of six birds labeled population 3. The birds in population 3, all resemble the two birds from population 2.

Return to Figure 43.4 Genetic drift

Extended description for: Figure 43.6 Founder effect

A rectangular cross-section of a landscape shows land on the left and water on the right with a small island to the upper right in the water. Eight birds are flying over the mainland. Four are very light, two are darker

with white wing stripes, and two are entirely dark. Accompanying text reads, 50 percent gray, 25 percent black, 25 percent black with white stripes. Three birds are enclosed in a circle, including two light birds and one dark bird with white wing stripes. An arrow points from this circle to text reading, The random founders of the new population, from which an arrow points to show a circle with the same birds over the small island. Accompanying text reads, Island, 67 percent gray, 0 percent black, 33 percent black with white stripes.

Return to Figure 43.6 Founder effect

Extended description for: Figure 43.7 The effect of population size on genetic drift

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

All of the graphs have a horizontal axis labeled generation that ranges from 0 to 100, in increments of 20. The vertical axis is labeled allele

frequency and ranges from 0 to 1, in increments of 0.2.

Graph a is labeled population size equals 4. A curve begins at (1, 0.5) and rises to (3, 0.85), then drops to (4, 0.78), then rises to (5, 1), and then runs horizontally to the right end of the graph at (100, 1). Accompanying text reads, A computer can model how the frequency of a given allele might randomly change over time because of genetic drift. In this simulation, the allele drifts from a frequency of 0.5 to fixation.

Part b is also labeled population size equals 4 and shows five curves. All of the curves begin at (1, 0.5). The first

curve is the same as in graph a. The second curve begins at the same point, then forms a jagged line in a generally diagonal line to the upper right to meet the horizontal line from the first curve at (8, 1) before running horizontally across the rest of the graph to end at (100, 1). The third curve initially runs jaggedly down to (10, 03), then forms a jagged line down to (4, 0.25), then rises to (10, 0.85), then down to (16, 0.78) for a slight almost horizontal piece before running almost vertically up to meet the top horizontal line at (12, 1) and then running horizontally across the rest of the graph to end at (100, 1). The fourth curve initially runs jaggedly down to (10, 0.25), then runs

jaggedly in a somewhat horizontal line before reaching (18, 0.25) and then running upward slightly to the right with a slight bend to meet the top horizontal line at (22, 1) before running horizontally across the rest of the graph to end at (100, 1). The fifth curve runs down to (3, 0.18), the goes up to (8, 0.5), then takes a jagged path down to (17, 0) before running horizontally across the bottom of the graph to end at (100, 0). The sixth curve runs down to (4, 0.17), then runs horizontally for a brief period, then runs up to (9, 0.38), then drops to (11, 0) before running horizontally across the bottom of the graph to end at (100, 0). Accompanying text reads, Each line represents a different

simulation of the effect of genetic drift on a population of 4 individuals. All simulations result in fixation or extinction of the allele in a few generations.

Part c is labeled population size equals 40. There are six simulations that all begin at (1, 0.5). One simulation takes a zigzag path up to peak at (32, 1) before running horizontally across the graph. The second takes a long zigzag path to reach the horizontal axis at (70, 1) before running horizontally across the graph. The third takes a zigzag path down to (38, 0.19) before running up to (62, 0.88) and then taking a zigzag path that goes up, then

down, then up again to end at (100, 0.90). The fourth takes a gradually descending zigzag path to end at (100, 0.24). The fifth rises slightly, then descends, rises slightly, then descends diagonally to reach the horizontal axis at (83, 0) before running horizontally to end at (100, 0). The sixth rises slightly, then drops rapidly to (18, 0.18), then rises slightly before taking a zigzag line down to (37, 0) before running horizontally across the horizontal axis to end at (100, 0). Accompanying text reads, Genetic drift is less dramatic in large populations.

Part d is labeled population size equals 100. There are six curves that

all begin at (1, 0.5) and gradually spread apart across the graph with the top one ending near (100, 0.81) and the bottom one ending at (100, 0.09). All of the others end in between these two. Accompanying text reads, After 100 generations of a large population, none of the simulations results in extinction or fixation of an allele. All data are approximate.

Return to Figure 43.7 The effect of population size on genetic drift

Extended description for: Figure 43.8 Migration

A circle at the lower left contains seven dark birds. A clockwise arrow points to text reading movement of individuals. Two dark birds are near this text. An arrow points from this text to a circle containing seven

lighter brown birds with patterns of darker lines and spots. An arrow points right to show a circle with two dark birds and five of the lighter birds.

Return to Figure 43.8 Migration

Extended description for: Figure 43.10 Mutation

The figure shows two vertical

columns with six birds in each. The left-hand column is labeled population 1, and the right-hand column is labeled population 2. The horizontally aligned birds are similar in coloration and pattern, and the birds become darker from top to bottom on each side. On the left, the fourth bird from the top is entirely a moderate dark brown with a slight pattern of brown spots on its breast. An arrow points right to the fourth bird on the right, which is identical except for two yellow bars on its wing with a narrow brown line between them. Text below the arrow reads, Mutation in one individual passed on to next generation.

Return to Figure 43.10 Mutation

Extended description for: Figure 43.11 Nonrandom mating

The illustration shows three vertical columns of six birds in each. The left

two columns are labeled population 1 and the right column is labeled population 2. The horizontally aligned birds in population 1 are similar in color and are progressively darker from top to bottom. A double-headed arrow labeled mating is between a bracket enclosing the top two birds in each column of population 1. A similar double-headed arrow labeled mating is between brackets enclosing the bottom two birds in each column of population 1. An arrow points right above the word generations to the third vertical column, labeled generation 2. The top three birds are all as light as the top two birds in population 1, and the bottom three

birds are all as dark as the bottom two birds in population 1.

Return to Figure 43.11 Nonrandom mating

Extended description for: Figure 43.12 Visual relationship between allele and genotype frequencies under the Hardy–Weinberg equilibrium

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The square has two rows of two square or rectangular boxes each, but the boxes are not even in size. The left side of the square is labeled sperm, with the top row labeled capital A and the bottom row labeled small a. The top of the square is labeled Eggs with the left-hand column labeled capital A and the right-hand column labeled small a. A bracket enclosing the bottom of the left column is labeled small p. A bracket enclosing the bottom of the right column is labeled small q. A bracket enclosing the right side of the top row is labeled small p. A bracket enclosing the right side of the bottom row is labeled small q. Each box is labeled with the values from its sides. The square box at the

upper left is the largest and is labeled capital A capital A (small p squared). The rectangular box at the lower left is medium-sized and is labeled capital A small a (small p small q). The rectangular box at the upper right is medium sized, is the same color as the box at the lower left, and is labeled capital A small a (small p small q). The square box at the lower right is the smallest and is labeled small a small a (small q squared).

Extended description for: Figure 43.13 Graphical relationship between allele and genotype frequencies under the Hardy–Weinberg equilibrium

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The horizontal axis is labeled Allele frequency. It has two rows of labels. The top label is small p (capital A) and ranges from 0 to 1.0, in increments of 0.2. The lower label is small q (small a) and ranges from 1.0 to 0, in increments of negative 0.2. The

vertical axis is labeled genotype frequency and ranges from 0 to 1.0, in increments of 0.1. Text below the horizontal axis reads, each line on the graph represents one of the three genotypes. A key indicates that the lines represent genotype small a small a, capital A small a, and capital A capital A. Using the values for the bottom label of the horizontal axis, small q (small a), the line for genotype small a small a begins at (1.0, 1.0) and descends with a slightly concave up shape to the lower right to end at (0, 0). Accompanying text reads, Genotype frequency of small a small a is small q squared. The curve for capital A small a begins at (0, 0) and (1.0, 0) for the top and bottom

horizontal axis labels, respectively. It rises symmetrically to a peak at (0.5, 0.5) with the horizontal axis label of 0.5 for both the top and bottom values. It ends at (1.0, 0) and (0, 0) for the top and bottom horizontal axis labels, respectively. Accompanying text reads, Genotype frequency of capital A small a is 2 small p small q. Using the values for the upper label of the horizontal axis, small p (capital A), the curve for capital A capital A begins at (0, 0) and rises with a slight concave up shape opening to the left to end at (1.0, 1.0) based on the upper horizontal axis label. Accompanying text reads, Genotype frequency of capital A capital A is small p squared. All data are approximate.

Return to Figure 43.13 Graphical relationship between allele and genotype frequencies under the Hardy–Weinberg equilibrium

Extended description for: Two graphs plot allele frequency against year for a large forest compared with an isolated forest patch

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Both graphs have a horizontal axis labeled year that ranges from 1980 to 2020, in increments of 10. The vertical axis is labeled allele frequency and

ranges from 0 to 1.0, in increments of 0.2. Both graphs have a dashed vertical line extending up from 1983 that is labeled housing development constructed. The left-hand graph is labeled Large forest. It has a line that passes through the following points: (1980, 0.76), (1985, 0.75), (1990, 0.73), (1995), (0.70), (2000, 0.80), (2005, 0.78), (2010, 0.79), (2015, 0.80), and (2020, 0.81). The right-hand graph is labeled Isolated forest patch. It has a line that passes through the following points: (1980, 0.76), (1985, 0.61), (1990, 0.61), (1995), (0.80), (2000, 0.90), (2005, 1.00), (2010, 1.00), (2015, 1.00), and (2020, 1.00). All data are approximate.

Return to Two graphs plot allele

frequency against year for a large forest compared with an isolated forest patch

Extended description for: Figure 44.1 Descent from a common ancestor

The phylogenetic tree shows a horizontal root on the left with an illustration of an egg containing an embryo within sacs. Text accompanying the egg reads, “The amniotic egg is a homology of reptiles, birds, and mammals because it evolved once in the common

ancestor." A horizontal line representing the root of the tree meets a vertical line that meets two horizontal lines. The bottom horizontal line extends right to end at the word Mammals. The upper horizontal line meets a vertical line that meets two horizontal lines. The top horizontal line extends to text reading Lizards and snakes, and the bottom horizontal line meets a vertical line that extends up to a horizontal line to turtles and down to a horizontal line to a final vertical line that meets two horizontal lines: a top horizontal line that extends to crocodiles and alligators and a bottom horizontal line that extends to birds. A bracket indicates that the lineages

labeled lizards and snakes, turtles, and crocodiles and alligators are reptiles. A larger bracket indicates that all of the lineages are amniotes.

Return to Figure 44.1 Descent from a common ancestor

Extended description for: Figure 44.2 An evolutionary tree showing the origin of walking legs

The root of the tree is a horizontal line on the left beneath a circle containing the bones of a vertebrate limb with a foot. There is a close-up of the limb with text reading, “Tetrapods have walking legs.” The

ancestral lineage meets a vertical line that meets horizontal lines above and below. The top horizontal line meets a vertical line that meets a top horizontal line that branches to frogs above and salamanders below and a bottom horizontal line that extends to caecilians. A bracket labels the frogs, salamanders, and caecilians as amphibians. The other end of the vertical line from the ancestral lineage meets a horizontal line that branches to a vertical line to a horizontal line to mammals below and to a horizontal line above that meets a vertical line that meets a horizontal line to lizards and snakes above and a horizontal line below that further meets a vertical line. This

vertical line meets a horizontal line to turtles above and a horizontal line below that meets another vertical line. This vertical line meets a top horizontal line that branches to crocodiles and alligators above and birds below. A bracket enclosing the lizards and snakes, turtles, and crocodiles and alligators is labeled reptiles. A bracket including all of the lineages indicates that they are all tetrapods.

Return to Figure 44.2 An evolutionary tree showing the origin of walking legs

Extended description for: Figure 44.3 Shared cellular traits in eukaryotes

The overall structure is roughly oval to rectangular with vertical, wavy sides and protrusions that extend out

to the lower right. The outer covering is labeled cell membrane. A large circular structure labeled nucleus has a dark circle at the lower left, a double-layer membrane, and pores in its surface. It is cut away to show the interior. There are strands of cytoskeleton above and throughout the cell. There are concentric layers of endoplasmic reticulum around the nucleus, depicted as double layers of membrane connected to adjacent layers by small vertical openings. There are several oval shaped structures, and one is cut away to show the interior and is labeled mitochondrion. It has a folded inner membrane. The material inside the cell is labeled cytoplasm. To the right

of the mitochondrion and below the endoplasmic reticulum is a structure consisting of a stack of double-membrane structures with a few vesicles around them. This is labeled Golgi apparatus.

Return to Figure 44.3 Shared cellular traits in eukaryotes

Extended description for: Figure 44.4 Vestigial structure

Morris, et al., *Biology for the AP* ® *Course*, 1e, © 2022
BFW High School Publishers

The skeleton is depicted within the outline of a baleen whale. It has a large, oval skull, and its forearm bones inside the flipper are depicted extending up to the rib cage beneath a vertebral column that runs to its tail. Near the end of the body before the tail is a small structure with four

bones: a bone extending in a curve to the left, a bone extending diagonally to the lower left to a small bone, and a bone extending to the lower right. This set of bones is labeled vestigial hip bones.

Return to Figure 44.4 Vestigial structure

Extended description for: Figure 44.5 A record of Earth's history at the Grand Canyon

Photo: National Park Service

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The Grand Canyon is depicted with elevated regions that have steep sides with smooth, flat edges where layers are visible. A diagonal white to sandy gray area runs from just beneath the

middle right to the lower middle, and accompanying text reads, Slopes made of mud laid down in a shallow sea about 500 million years ago contain fossils of early arthropods called trilobites. Reddish layers above these form angled slopes. Accompanying text reads, Limestone accumulated in the oceans about 335 million years ago, trapping marine animals. Almost vertical white areas appear above these red areas near the top of the canyon. Accompanying text reads, White beds contain fossilized tracks of vertebrate animals that lived about 260 million years ago.

Return to Figure 44.5 A record of Earth's history at the Grand Canyon

Extended description for: Figure 44.6 Unicellular organisms with skeletons

a.

b.

c.

Photos (a): Gert Hansen, SCCAP, University of Copenhagen; (b): Astrid & Hanns-Frieder Michler/Science Source; (c): M. I. Walker/Science Source

Part a shows a wide cylindrical structure with narrow tubular structures in the background. The

main cylindrical structure has many small openings in the top and bottom and two concentric rings of openings above and below its middle. It is approximately 20 micrometers in diameter and approximately 35 micrometers in length.

Part b shows a variety of cross-sections small shells in shapes including various spirals, segmented spirals, cones made of cells in a herringbone pattern, and clusters of multiple circles of varying sizes. Each shell is about 100 to 200 micrometers in length.

Part c shows clear, glass-like skeletons in circular, cylindrical, and

bell shapes. The largest ones are about 150 micrometers, but many are smaller, and most are made of a fine lace-like mesh.

Extended description for: A photo and a timeline show how Tiktaalik fits in between the fish and tetrapods

Photo: Neil Shubin Lab
Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A timeline extends from left to right and is labeled beginning at

approximately one-quarter of its length, from 390 to 360 millions of years ago in decrements of 10, and ending three-quarters of the way across. Narrow lines extend upward from the timeline and broaden beneath illustrations of organisms. From left to right, the organisms are as follows. Eusthenopteron, a thin fish with a bony skull: 385 to 384 million years ago; Panderichthys, a thin fish with paddle-like fins: 384 to 383 million years ago; Tiktaalik, a thick organism with a broad head, eyes on the top of its head, and fins that look somewhat like limbs: 375 to 374 million years ago; Acanthostega, a thin animal with wide, paddle-like fins around its tail and limbs: 364 to

362 million years ago; Ichthyostega, a thick animal with a narrow head, a thin fin around its tail, and clear limbs positioned to the sides of its body: 363 to 361 million years ago. All data are approximate. Eusthenopteron and Panderichthys are identified as fish. Acanthostega and Ichthyostega are identified as tetrapods.

A photo below the timeline shows the fossil of Tiktaalik along with its reconstructed model. Tiktaalik is depicted as having a broad, wedge-shaped head with eyes on top, broad limbs that end with parts that look like fins, and scales.

Return to A photo and a timeline show how Tiktaalik fits in between the fish and tetrapods

Extended description for: Figure 44.10 Carbon dating

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The illustration begins at the top, showing cosmic radiation from the sun hitting neutrons, depicted as spheres that are moving in curved

paths. A neutron then reacts with nitrogen-14, depicted as a ball of spheres representing protons and neutrons, to yield carbon-14, also depicted as a sphere of protons and neutrons, and one proton. Accompanying text reads, “In the atmosphere, neutrons generated by cosmic radiation can collide with N left superscript 14 to create C left superscript 14.” An arrow from the carbon-14 points to a space-filling model of carbon dioxide, depicted as a large sphere with smaller spheres on the left and right sides. Another arrow points down to an illustration of a tree being grazed by giraffe. Accompanying text reads, “C left superscript 14 that ends up in carbon

dioxide can be incorporated into plants through photosynthesis. C left superscript 14 is next incorporated into animals when they eat the plants. After the plant or animal dies and is buried, its C left superscript 14 decays to the more stable N left superscript 14." An arrow points downward to wood and an animal skull under the soil from which carbon-14 turns to nitrogen-14 and an electron. Accompanying text reads, "Half of the C left superscript 14 in a fossil turns to N left superscript 14 in 5730 years. In another 5730 years, half of the remaining C left superscript 14 decays to N left superscript 14, and so on."

Return to Figure 44.10 Carbon dating

Extended description for: Figure 44.11 Half-life

The horizontal axis is labeled years elapsed and ranges from 0 to 28,650, in increments of 5730. The vertical axis is labeled percent carbon-14 remaining and ranges from 0 to 100, in increments of 25. A curve begins at (0, 100) and forms a concave up shape as it drops to end just above the

horizontal axis at (28,650, 3.125). Each increment on the horizontal axis represents a half life, and the ranges between them under the curve are colored differently, becoming paler from left to right. The amount of carbon at each half life is as follows: (5730, 50); (11,460, 25); (17,190, 12.5); (22,920, 6.25); and (28,650, 3.125). All data are approximate.

Return to Figure 44.11 Half-life

Extended description for: Figure 45.1. Two groups of whales

a.

b.

Photos: (a) M Swiet Productions/Getty Images; (b) Nature Picture Library/Alamy Stock Photo

Part a shows a humpback whale

breeching out of the water. It has many lines along the underside of its body and long, thin flippers. Part b shows an orca (killer whale) as a mostly black whale with a white oval near its eye, white on the bottom of its head, and a curved white patch on its ventral side in the region between its dorsal fin and its tail. Its head is short and thick, and its fins shorter and wider, compared to the humpback whale.

Return to Figure 45.1. Two groups of whales

Extended description for: Figure 45.2 Whale evolution

Morris, et al., *Biology for the AP* Course*, 1e, © 2022 BFW High School Publishers

The timeline is depicted horizontally at the bottom and indicates millions of years ago ranging from 55 to 0, in increments of 5. A short horizontal line representing the root of the tree is at the upper left. It extends to a vertical line at 54 million years ago that branches to horizontal lines above and below. The upper line extends right to 47 millions of years ago and the word Pakicetus next to a dog-like animal. The lower line extends to a horizontal line that extends to a vertical line at 50 million years ago that meets horizontal lines above and below. The top horizontal line extends to 45 million years ago and the word Ambulocetus, which is similar to Pakicetus except that its

lower body is resting on the ground, its rear feet bend forward, and its tail is lying on the ground. The bottom horizontal line extends to a vertical line at 50 million years ago that extends up to a horizontal line that extends to 44 million years ago and the word Dalanistes next to an animal with a streamlined body, thick tail, and limbs that extend to the sides. The bottom horizontal line extends to a vertical line at 47 million years ago that extends up to a horizontal line to 44 million years ago to the word Rodhocetus, which has an almost whale-like shape with a wavy body and elongated limbs. The vertical line extends down to a horizontal line to a vertical line at 47 million years ago

that extends up to a horizontal line to 44 million years ago and Takracetus, which looks like an irregularly shaped whale with four limbs, a slightly bifurcated tail fin, and a long snout. The line extends down to a horizontal line that meets a vertical line at 45 millions of years ago that meets a horizontal line above that extends to 43 million years ago and the word Gaviocetus next to a whale-like animal with four flippers and a long, slightly finned tail. The vertical line extends down to a horizontal line that extends to a vertical line at 43 million years ago that extends up to a line to 35 million years ago that is labeled Durodon next to a whale-like creature with a large, rounded head, very

small rear limbs or fins, and a wider tail fin. The vertical line also extends down to a short horizontal line to a vertical line at 41 million years ago that extends up to a line to 35 million years ago and the word Basilosaurus next to a long, thin whale-like animal with no rear appendages. The line also extends down to a horizontal line that extends right to a vertical line at 33 million years ago that extends to a horizontal line above labeled Mysticetes and a horizontal line below labeled Odontocetes, both of which extend to 0 millions of years ago. The Mysticetes is a baleen whale that appears to be a right whale, and the Odontocetes is a type of dolphin. All data are approximate.

Return to Figure 45.2 Whale evolution

Extended description for: Figure 45.3 Evolution of larger beaks in response to a drough

Two illustrations show the smaller

beak size of the finches hatched in 1976, the year before the drought, and larger beak size of the finches hatched in 1978, the year after the drought. Each illustration is accompanied by a graph. In both graphs, the horizontal axis represents beak size (depth in millimeters) and ranges from 7.3 to 11.3 millimeters, in increments of 0.5. The vertical axis represents number of finches and ranges from 0 to 40, in increments of 5.

Graph (a) shows distribution of beak sizes in 1976. The data from the graph are as follows: 7.3 millimeters, 2 finches; 7.8 millimeters, 8 finches; 8.3 millimeters, 15 finches; 8.8

millimeters, 26 finches; 9.3 millimeters, 16 finches; 9.8 millimeters, 11 finches; 10.3 millimeters, 2 finches; 10.8 millimeters, 2 finches; 11.3 millimeters, 0 finches. A clear maximum exists at 8.8 millimeters.

Graph (b) shows the distribution of beak sizes in 1978. The data from the graph are as follows: 7.3 millimeters, 2 finches; 7.8 millimeters, 2 finches; 8.3 millimeters, 6 finches; 8.8 millimeters, 21 finches; 9.3 millimeters, 34 finches; 9.8 millimeters, 37 finches; 10.3 millimeters, 19 finches; 10.8 millimeters, 15 finches; 11.3 millimeters, 3 finches. The maximum

is around 9.9 millimeters. Text above the graph reads: Directional selection shifts the population mean.

All data are approximate.

Return to Figure 45.3 Evolution of larger beaks in response to a drough

Extended description for: Figure 45.5 Distribution of extremely drug-resistant tuberculosis around the world

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The areas of highest concentration are Russia and other parts of northern and central Asia, with more than 18 percent of new T B cases with multidrug-resistant tuberculosis.

China, Australia, southern Africa, Peru, Spain, and a few countries in western Africa have moderate numbers of cases, between 3 and 11 percent. North America, western South America, southern and southwest Asia, and some western European and eastern African countries have low incidence (less than 2.9 percent). Data are not available for some countries, including most of western Africa, Greenland, Ecuador, Bolivia, and Iran.

Return to Figure 45.5 Distribution of extremely drug-resistant tuberculosis around the world

Extended description for: Figure 45.9 Plant response to warming temperatures

Part a shows a graph with a horizontal axis labeled Year that ranges from 1850 to 2010, in increments of 40. The vertical axis is labeled mean annual temperature (degrees C) and ranges

from 0.0 to 12.0, in increments of 1. A line with many zigzags begins at (1851, 7.7) and takes an up-and-down-path that follows a general diagonal path toward the upper right to end at (1009, 10.3). Accompanying text reads, “Mean annual temperature has fluctuated but generally increased over the last 150 years.”

Part b shows a graph with a horizontal axis labeled Year that ranges from 1850 to 2010, in increments of 4. The vertical axis is labeled Mean first flowering date and ranges from May 4 to May 22, in increments of 9 days. A horizontal red line at 1851 and May 14 has error bars extending approximately 1 day above

and below. A horizontal red line at 1900 at May 11 has error bars extending approximately 0.5 days above and below. A horizontal red line at 2008 and May 6 has error bars extending approximately 0.75 days above and below. All data are approximate. Accompanying text reads, “Red lines indicate the mean date of first flower formation for 33 native and 10 invasive species, as measured in three surveys over 152 years.”

Return to Figure 45.9 Plant response to warming temperatures

Extended description for: Figure 45.10 Estimated sensitivity of global vegetation to twenty-first-century climate change

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The map shows areas of low vegetation sensitivity, middle vegetation sensitivity, and high vegetation sensitivity. Middle to low sensitivity is dominant in most of the

regions of the world, with scattered patches of high and low sensitivity. Low sensitivity is dominant in Australia, while a wide band of high sensitivity runs across most of Russia and the west part of North America at approximately the same latitude. Another band of high sensitivity appears across northern South America, the southern coast of western Africa, and parts of Southeast Asia, also at approximately the same latitudes. Text above North America reads, “In many parts of the world, plants are most vulnerable to changing rainfall.” Text above Russia reads, “Arctic vegetation is especially vulnerable to increasing temperatures.” Text below Africa

reads, “Tropical rainforests are vulnerable to the combined effects of increasing temperature and decreasing cloud cover.” No data is illustrated for desert regions, including Greenland, northern Africa and parts of the Middle East, and the Gobi area of China.

Return to Figure 45.10 Estimated sensitivity of global vegetation to twenty-first-century climate change

Extended description for: Three different types of graphs and a pie chart show ways to present data on birds observed in different years

Morris, et al., *Biology for the AP* Course*, 1e, © 2022 BFW High School Publishers

Part a is a line graph with a horizontal axis labeled Number of italic L. coeruleocapilla end italic observed, ranging from 0 to 30 in increments of 5. A vertical axis is labeled elevation, ranging from 0 to 1600 in increments of 200. The curve for 1985 follows the horizontal axis except for peaks at the following points: (1, 910), (22, 1390), and (24, 1100). The curve for 2017 also follows the horizontal axis except for the following peaks: (10, 1100) and (29, 1390).

Part b is a bar graph with a horizontal axis labeled elevation (m) ranging from below 470 to above 1070 in varying increments. A vertical axis is labeled number of birds observed,

ranging from 0 to 30 in increments of 5. At 810, there is a bar for 1985 with a height of 1. At 1050, there is a bar for 1985 with a height of 24 and a bar for 2017 with a height of 10. For 1350, there is a bar for 1985 with a height of 22 and a bar for 2017 with a height of 29.

Part c is a scatterplot with a horizontal axis labeled 1985 that ranges from 0 to 30 in increments of 5. A vertical axis is labeled 2017, ranging from 0 to 35 in increments of 5. The points on the graph are as follows: (0, 0), (1, 0), (22, 29), and (24, 10).

Part d is a pie graph labeled Number

of italic L. coeruleocapilla end italic observed. Just over half the graph is shaded to represent 2017, and the rest represents 1985.

All data are approximate.

Extended description for: Figure 46.1 A phylogenetic tree of chimpanzees, humans, cows, and their ancestors

Morris, et al., *Biology for the AP® Course, 1e,*
© 2022 BFW High School Publishers

An arrow beneath the phylogenetic tree points to the right and is labeled time. On the left, a short horizontal line is labeled on its left end as root

and meets a vertical line on its right end. This vertical line meets a short horizontal line above and a longer horizontal line below that runs all the way to the right end of the phylogeny to the word cows. The upper short horizontal line meets a vertical line at a point labeled node. This vertical line meets horizontal lines above and below that each run all the way to the right end of the phylogeny. The upper horizontal line is labeled branch and ends at the word chimpanzees, which is labeled taxon. The lower horizontal line is labeled humans.

Return to Figure 46.1 A phylogenetic tree of chimpanzees, humans, cows, and their ancestors

Extended description for: Figure 46.2 Close and distant relationships on a phylogenetic tree

On the left, a short horizontal line meets a vertical line on its right end at a point labeled, Most recent common ancestor of cows, chimpanzees, and humans. This vertical line meets a short horizontal line above and a longer horizontal

line below that runs all the way to the right end of the phylogeny to the word cows. The upper short horizontal line meets a vertical line at a point labeled, Most recent common ancestor of chimpanzees and humans. This vertical line meets horizontal lines above and below that each run all the way to the right end of the phylogeny. The upper horizontal line ends at the word chimpanzees. The lower horizontal line is labeled humans.

Return to Figure 46.2 Close and distant relationships on a phylogenetic tree

Extended description for: Figure 46.3 Rotating nodes

On the left, a short horizontal line meets a vertical line on its right end. This vertical line meets a short horizontal line above and a longer horizontal line below that runs all the way to the right end of the phylogeny to the word cows. The upper short horizontal line meets a vertical line at

a point with a circle over the intersection between the lines. This vertical line meets horizontal lines above and below that each run all the way to the right end of the phylogeny. The upper horizontal line ends at the word humans. The lower horizontal line is labeled chimpanzees.

Return to Figure 46.3 Rotating nodes

Extended description for: Figure 46.4 Tree styles

Part a: On its left end, a short horizontal line meets a vertical line to the right. This vertical line meets a short horizontal line above and a longer horizontal line below that runs all the way to the right end of the phylogeny to the word cows. The

upper short horizontal line meets a vertical line. This vertical line meets horizontal lines above and below that each run all the way to the right end of the phylogeny. The upper horizontal line ends at the word chimpanzees. The lower horizontal line is labeled humans.

Part b: On its right end, a short horizontal line meets a vertical line to the left. This vertical line meets a short horizontal line above that runs all the way to the left end of the phylogeny and the word cows and a shorter horizontal line below. The lower short horizontal line meets a vertical line. This vertical line meets horizontal lines above and below that

each run all the way to the left end of the phylogeny. The upper horizontal line ends at the word humans. The lower horizontal line is labeled chimpanzees.

Part c: The tree begins with a short vertical line at the bottom that meets a horizontal line. The horizontal line meets a short vertical line on the left and a long vertical line on the right that runs to the top of the phylogeny to end at the word cows. The short vertical line meets a horizontal line that meets vertical lines on its left and right ends that both run to the top of the phylogeny. The left-hand line ends at the word chimpanzees, and the right-hand line ends at the word

humans.

Part d: The tree begins at the lower right with a diagonal line it runs up and left to the word chimpanzees. Two diagonal lines running up and to the right branch off of the original line and extend to the top of the phylogeny. Of these two diagonal lines that branch from the main line, the lower line runs to the word cows and the upper, shorter one runs to the word humans.

Return to Figure 46.4 Tree styles

Extended description for: Figure 46.5 A phylogenetic tree of vertebrate animals

The phylogenetic tree begins with a short horizontal line at the upper left

that meets a vertical line to the right that meets horizontal lines above and below. The upper horizontal line runs right to meet a short vertical line that meets short horizontal lines above and below that run to the right end of the tree to hagfish and lampreys, respectively. The lower horizontal line from the first branch point meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to sharks and rays. The lower horizontal line meets a vertical line that meets horizontal lines above and below. The upper line runs right to ray-finned fish, and the bottom line meets a vertical line that meets horizontal lines above and below. The upper

horizontal line runs right to coelacanths, and the lower horizontal line meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to lungfish, and the lower horizontal line runs to a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to meet a vertical line that branches to frogs above and to salamanders below. The lower horizontal line runs right to caecilians. Going back to the vertical line with an upper branch point that led to the frogs, salamanders, and caecilians, the lower horizontal line runs to a vertical line that meets a short horizontal line above and a horizontal

line below that runs to mammals. The upper horizontal line runs to a vertical line that meets a horizontal line above to lizards and snakes and a short horizontal line below that meets a vertical line. This vertical line meets a horizontal line above that runs to turtles and a short horizontal line below that meets a vertical line that meets short horizontal lines to crocodiles and alligators above and birds below. Brackets label adjacent groups of taxa on the phylogeny. Hagfish and lampreys are labeled jawless fish. Sharks and rays are cartilaginous fish. Coelacanths and lungfish are lobe-finned fish. A larger bracket indicates that ray-finned fish and lobe-finned fish are bony fish.

Frogs, salamanders, and caecilians are amphibians. Lizards and snakes, turtles, crocodiles and alligators, and birds are sauropsids. A larger bracket indicates that amphibians, sauropsids, and mammals are tetrapods.

Return to Figure 46.5 A phylogenetic tree of vertebrate animals

Extended description for: Figure 46.6 Equivalent trees

Morris, et al., *Biology for the AP® Course, 1e,*
© 2022 BFW High School Publishers

Four phylogenetic trees are depicted with equals sign between them. The left-hand tree begins with a short horizontal line on the left that meets a vertical line that meets a horizontal line above to turtles and a short horizontal line below. The lower horizontal line meets a vertical line that meets a horizontal line to

crocodiles and alligators above and a line to birds below.

The second tree is similar except that there is a curved arrow pointing up and over the bottom horizontal line of the first branch, and the node has been rotated so that its upper horizontal line runs to birds and its lower horizontal line runs to crocodiles and alligators. Text above the first two trees reads, “The four trees are equivalent because nodes can be rotated without changing evolutionary relationships.”

The third tree begins with a short horizontal line on the left that has a curved arrow pointing up and over it

to indicate that the node has been rotated. This line meets a vertical line that meets horizontal lines above and below. The lower line runs to turtles, and the upper line meets a vertical line that meets horizontal lines above and below with the upper line running to crocodiles and alligators and the lower line running to birds.

The fourth horizontal tree is similar to the third tree except that the curved arrow points up and over the upper horizontal line from the first branch point so that it meets a vertical line that meets an upper horizontal line to birds and a lower horizontal line to crocodiles and alligators.

Return to Figure 46.6 Equivalent trees

Extended description for: Figure 46.7 The Linnaean classification system

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The figure shows seven horizontal

lines representing different levels of classification. From top to bottom, the lines are labeled Kingdom Animalia, Phylum Chordata, Class Mammalia, Order Carnivora, Family Canidae, Genus italicized Canis end italics, and Species italicized Canis lupis end italics. Illustrations of animals appear along each line to show what is included. Kingdom Animalia has a wolf on the left followed by a domestic dog, then an animal that appears to be a coyote. Next, there is a similar animal with a bushy tail followed by a fox with a bushy tail that both have a similar overall shape to the coyote. Next, there is a polar bear, a lion, and a raccoon. A line of animals above this

line shows a bat, a Monarch butterfly, a jellyfish, a crab, an octopus, an alligator, a bald eagle, and a kangaroo. A line of animals above this line shows a blue whale and a large shark. Phylum Chordata shows the same bottom line of animals beginning with the wolf. Above, a second line shows the blue whale, an alligator, a shark, a bald eagle, and a kangaroo. Class Mammalia is similar to Phylum Chordata except that the alligator, shark, and bald eagle have been removed. Order Carnivora is similar to Class Mammalia except that the blue whale and kangaroo have been removed. Family Canidae is similar to Order Carnivora except that the polar bear, lion, and raccoon have

been removed. Genus italicized Canis end italics is similar to Family Canidae except that the red fox has been removed. Species italicized Canis lupis end italics includes only the wolf and the domestic dog.

Return to Figure 46.7 The Linnaean classification system

Extended description for: Figure 46.8 Relationship between the Linnaean classification system and the evolutionary process

The phylogenetic tree begins with a short horizontal line on the left labeled Phylum 1 that meets a vertical

line that meets a horizontal line below that is labeled Class 2 and fades to the right and a horizontal line above labeled Class 1. The line labeled Class 1 meets a vertical line that meets horizontal lines above and below labeled Order 1 and Order 2, respectively. The line labeled Order 1 is dark blue and meets a dark blue vertical line above that meets a lighter blue horizontal line labeled Family 1 above and a dark blue horizontal line below labeled Family 2 on the left and Genus 3 in the middle before ending at Species 6 on the right. The line labeled Family 1 meets a similarly colored vertical line that meets horizontal lines above and below. The upper horizontal line is

pale blue and labeled Genus 1, and the lower horizontal line is blue and labeled Genus 2. The line labeled Genus 1 meets a short vertical line that meets horizontal lines above and below that end at Species 1 and Species 2, respectively. The line labeled Genus 2 meets a vertical line that meets horizontal lines above and below. The upper horizontal line meets a vertical line that meets horizontal lines above and below that end at Species 3 and Species 4, respectively. The lower horizontal line ends at Species 5. The vertical line that shows branches of Class 1 meets a brown horizontal line below labeled Order 2 that meets a brown vertical line that meets horizontal

lines above and below. The upper horizontal line is red and labeled Family 3, and the lower horizontal line is dark pink and labeled Family 4. The line labeled Family 3 meets a red vertical line that meets a red horizontal line above labeled Genus 4 and a lighter red horizontal line below labeled Genus 5. The line labeled Genus 4 meets a red vertical line that meets a red horizontal line above that ends at Species 7 and a red horizontal line below that meets a red vertical line that meets red horizontal lines above and below labeled Species 8 and Species 9, respectively. The vertical line branching from Family 3 meets a lighter red horizontal line below that ends at Species 10. The

vertical line that meets the horizontal line labeled Order 2 also meets a purple horizontal line below labeled Family 4 that meets a purple vertical line that meets horizontal lines above and below. The upper horizontal line is pink and labeled Genus 6 and the lower horizontal line is bright red and labeled Genus 7. The line labeled Genus 6 meets a pink vertical line that meets pink horizontal lines above and below. The upper horizontal line meets a pink vertical line that meets pink horizontal lines above and below labeled Species 11 and Species 12, respectively. The lower horizontal line meets a pink vertical line that meets pink horizontal lines above and below

labeled Species 13 and Species 14, respectively. The line labeled Genus 7 meets a bright red vertical line that meets a bright red horizontal line above that ends at Species 15 and a bright red horizontal line below that meets a bright red vertical line that meets bright red horizontal lines above and below to Species 16 and Species 17, respectively.

Return to Figure 46.8 Relationship between the Linnaean classification system and the evolutionary process

Extended description for: Figure 46.9 Clades

The phylogenetic tree begins with a short horizontal line at the upper left that meets a vertical line to the right that meets horizontal lines above and

below. The upper horizontal line runs right to meet a short vertical line that meets short horizontal lines above and below that run to the right end of the tree to hagfish and lampreys, respectively. The lower horizontal line from the first branch point meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to sharks and rays. The lower horizontal line meets a vertical line that meets horizontal lines above and below. The upper line runs right to ray-finned fish, and the bottom line meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to coelacanths, and the lower horizontal

line meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to lungfish, and the lower horizontal line runs to a vertical line that meets horizontal lines above and below. The upper horizontal line runs through a blue pair of scissors right to meet a vertical line that meets an upper horizontal line to blue highlighted frogs and a lower horizontal line to blue highlighted salamanders. The lower horizontal line runs right to blue highlighted caecilians. Frogs, salamanders, and caecilians are included in a blue highlighted bracket labeled amphibians. Going back to the vertical line with an upper branch point that led to the amphibians,

there is a lower horizontal line that meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs through green scissors to a vertical line that meets a horizontal line above to green highlighted lizards and snakes and a short horizontal line below that meets a vertical line. This vertical line meets a horizontal line above that runs to green highlighted turtles and a short horizontal line below that meets a vertical line that meets short horizontal lines to green highlighted crocodiles and alligators above and unhighlighted birds below. Lizards and snakes, turtles, and crocodiles and alligators are included in a green-highlighted bracket labeled reptiles.

Green scissors appear over the horizontal line to birds. Going back to the vertical line that met the line to the reptiles and birds above, a lower horizontal line extends right to meet a vertical line that meets a horizontal line to marsupials below and a short horizontal line above that meets a vertical line. This vertical line meets a line to primates below and a short horizontal line above that meets a vertical line that meets horizontal lines above and below to bats and pigs, respectively. Text to the left of the bracketed amphibians reads, “A monophyletic group or clade (blue) includes a common ancestor and all of its descendants.” Text to the left of the bracketed reptiles reads, “A

paraphyletic group (green) includes a common ancestor and some, but not all, of its descendants.”

Return to Figure 46.9 Clades

Extended description for: Figure 46.10 Homology and analogy

The phylogenetic tree begins with a short horizontal line on the left that is overlain by a circle containing an egg. The egg contains an embryo surrounded by a membrane. Accompanying text reads, “The

amniotic egg is a homology of sauropsids and mammals because it evolved once in a common ancestor." The horizontal line overlaid by an egg meets a vertical line that meets horizontal lines above and below. The lower horizontal line is overlaid by a circle enclosing the end of a wing and ends at mammals (bats). The upper horizontal line meets a vertical line that meets horizontal lines above and below with the upper horizontal line ending at lizards and snakes and the lower horizontal line meeting a vertical line. This vertical line meets a horizontal line above to turtles and a horizontal line below to a vertical line. This vertical line meets at a horizontal line above that ends at

crocodiles and alligators and a horizontal line below that is overlain by a circle enclosing the end of a wing and that ends at birds. A bracket enclosing the lizards and snakes, turtles, crocodiles and alligators, and birds indicates that they are all sauropsids. Text below reads, “The presence of wings in birds and bats is an analogy because wings evolved independently in birds and bats, and were not present in their common ancestor.”

Return to Figure 46.10 Homology and analogy

Extended description for: Figure 46.11 Shared derived characters of vertebrate animals

The phylogenetic tree begins with a

short horizontal line at the upper left that meets a vertical line to the right that meets horizontal lines above and below. The upper horizontal line runs right to meet a short vertical line that meets short horizontal lines above and below that run to the right end of the tree to hagfish and lampreys, respectively. The lower horizontal line from the first branch point is labeled with a circle showing a jaw and meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to sharks and rays. The lower horizontal line meets a vertical line that meets horizontal lines above and below. The upper line runs right to ray-finned fish, and the bottom line, which is

labeled with a circle showing a lobed fin, meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to coelacanths, and the lower horizontal line, which is labeled with a circle showing a pair of lungs, meets a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to lungfish, and the lower horizontal line, which is labeled with a circle showing the skeleton of a limb, runs to a vertical line that meets horizontal lines above and below. The upper horizontal line runs right to meet a vertical line that meets an upper horizontal line to frogs and a lower horizontal line to salamanders. The lower horizontal

line runs right to caecilians. Going back to the vertical line with an upper branch point that led to the frogs, salamanders, and caecilians, the lower horizontal line, which is labeled with an amniotic egg showing an embryo inside a protective sac, runs to a vertical line that meets a short horizontal line above and a horizontal line below that runs to mammals and that is labeled with a circle showing a lobed milk gland and a circle showing hair. The upper horizontal line runs to a vertical line that meets a horizontal line above to lizards and snakes and a short horizontal line below that meets a vertical line. This vertical line meets a horizontal line above that runs to

turtles and a short horizontal line below that meets a vertical line that meets short horizontal lines to crocodiles and alligators above and birds below. Brackets label adjacent groups of taxa on the phylogeny. Hagfish and lampreys are jawless fish. Sharks and rays are cartilaginous fish. Coelacanths and lungfish are lobe-finned fish. A larger bracket indicates that ray-finned fish and lobe-finned fish are bony fish. Frogs, salamanders, and caecilians are amphibians. Lizards and snakes, turtles, crocodiles and alligators, and birds are sauropsids. A larger bracket indicates that amphibians, sauropsids, and mammals are tetrapods. On the left, each of the

circles with enclosed traits is connected with a line to the respective circle on the phylogeny and accompanying text. The text accompanying each circle is as follows. “Jaw: Sharks, ray-finned fish, coelacanths, lungfish, and tetrapods have a hinged jaw. Lobed fin: Coelacanths and lungfish have lobed fins. Lungs: Lungfish and tetrapods have lungs. Skeleton of limb: Tetrapods have walking legs. Amniotic egg: Saurosids and mammals have an amniotic egg. (Among mammals, only the platypus and echidna lay eggs. This trait has been lost in other mammals). Hair and milk gland: Mammals have hair and milk glands.”

Return to Figure 46.11 Shared derived characters of vertebrate animals

Extended description for: Figure 46.12 Phylogenetic trees of horses, humans, and lizards

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a shows a tree that begins with a

short horizontal line on the left. This line meets a vertical line that meets a horizontal line below to lizards next to an illustration of a lizard and a horizontal line above that meets a vertical line and that is accompanied by text reading, “Mammary glands, hair, three middle ear bones.” This vertical line meets horizontal lines above and below to horses next to an illustration of a horse and Humans next to an illustration of two humans, respectively.

Part b shows an identical tree except that the horizontal line leading to horses and humans is now labeled “Warm-bloodedness.”

Return to Figure 46.12 Phylogenetic trees of horses, humans, and lizards

Extended description for: Figure 46.13 The evolution of hooves and hands from a five-fingered tetrapod

On the left, text reads, “Proterogyrinus, 5 fingers” next to a horizontal line representing the root of the tree. This horizontal line runs right to meet a vertical line that meets horizontal lines above and below. The upper horizontal line ends at “horses, 1 finger (hoof)” next to an illustration

of a horse's hoof. The lower horizontal line ends at “humans, 5 fingers” next to the illustration of a human hand with the fingers spread.

Return to Figure 46.13 The evolution of hooves and hands from a five-fingered tetrapod

Extended description for: Figure 46.14 Outgroup comparison

A short horizontal line on the left is labeled C A 1 and meets a vertical line that meets horizontal lines above and below. The lower horizontal line ends at “lizards, 5 fingers” next to an illustration of a lizard foot with five fingers that each ends in claws. The

upper horizontal line meets a vertical line at a point labeled C A 2. This vertical line meets horizontal lines above and below. The upper horizontal line ends at “horses, 1 finger (hoof)” next to an illustration of a horse's hoof. The lower horizontal line ends at “humans, 5 fingers” next to an illustration of a human hand with the fingers spread.

Return to Figure 46.14 Outgroup comparison

Extended description for: Figure 46.15 Building a phylogenetic tree using distance methods

The illustration shows the gene sequences of human, chimp, gorilla, and gibbon with some individual bases highlighted. Human: T highlighted T G G highlighted A A T T A T A highlighted G G highlighted G T

T A A A highlighted G highlighted T G G G highlighted C A highlighted A G highlighted T G; Chimp: T highlighted T G G highlighted A A T T A T A highlighted G G highlighted G T T A A A highlighted G highlighted T G G G highlighted T A highlighted G G highlighted T G; Gorilla: T highlighted T G G highlighted A A T T A T A highlighted A G highlighted G T T A A A highlighted G highlighted C G G G highlighted C A highlighted G G highlighted C G; Gibbon: T highlighted A G G highlighted C A T T A T A highlighted G G highlighted C T T A A A highlighted T highlighted C G G G highlighted C A highlighted G G highlighted T G. The second, fifth, twelfth, fourteenth, twentieth, twenty

first, twenty fifth, twenty seventh, and twenty ninth base from the left to right are highlighted in all of the subjects. The nonhighlighted bases are the same for all subjects.

A dashed arrow points through text to a table with two columns and four rows. The text reads, “We count the differences between each pair of species and add the number to the table.” The left-hand column is labeled “Number of differences between pairs of taxa,” and the right-hand column is labeled “Taxon.” The right-hand column is subdivided into four columns labeled from left to right as H u, C h, G o, G i. Data from the table is as follows.

Row 1: Taxon Human, H u dash, C h 2, G o 4, G i 6.

Row 2: Taxon Chimp, H u 2, C h dash, G o 4, G i 6.

Row 3: Taxon Gorilla, H u 4, C h 4, G o dash, G i.

Row 4: Taxon Gibbon, H u 6, C h 6, G o 6, Gi dash.

Highlighted bars extend down from the top of the subcolumns labeled C h, G o, and G i as follows. C h: Orange bar including 2 in row 1 for humans. G o: Green bar including 4 in row 1 for humans and 4 in row 2 for chimps. G i: Blue bar including 6 in row 1 for humans, 6 in row 2 for chimps, and 6

in row 3 for gorillas.

Three arrows point right from the table to three phylogenies to illustrate three steps in building a phylogeny. An upper orange arrow points right to a phylogeny representing Step 1: We pair the closest taxa. The phylogeny begins with a short vertical line that meets a horizontal line that meets vertical lines to the left and right to H u and C h, respectively. Accompanying text reads, “Humans and chimps are most closely related because they have the fewest sequence differences.” A middle green arrow points right to a phylogeny representing Step 2: We add the next closest. The phylogeny

begins with a short vertical line that meets a horizontal line that meets a vertical line on the left to G o and a vertical line on the right that branches to the left and right to H u and C h, respectively. A bottom blue arrow points right to a phylogeny representing Step 3: We add the last. The phylogeny begins with a short vertical line that meets a horizontal line that branches on the left to G i and a vertical line on the right that meets a horizontal line branches to the left and right. The left-hand vertical line ends at G o. The right-hand vertical line meets a horizontal line that branches to the left and right to H u and C h, respectively. An arrow points right to show a phylogenetic

tree above text reading, “This is the final tree based on sequence differences.” The phylogeny begins with a short vertical line that meets a horizontal line that branches on the left to gibbon and a vertical line on the right that branches to the left and right. The left-hand vertical line ends at gorilla. The right-hand vertical line branches to the left and right to chimp and human, respectively.

Return to Figure 46.15 Building a phylogenetic tree using distance methods

Extended description for: Figure 46.16 Correct and incorrect phylogenetic trees of sharks, rays, and bony fish

Part a is labeled, Correct phylogenetic

tree. The tree begins with a short horizontal line on the left that meets a vertical line. This vertical line meets a horizontal line below that ends at bony fish next to an illustration of a bony fish and meets a horizontal line above that meets a vertical line. This vertical line meets a horizontal line above to sharks next to an illustration of a shark and a horizontal line below to rays next to an illustration of a ray.

Part b is labeled, Incorrect phylogenetic tree. The tree begins with a short horizontal line on the left that meets a vertical line. This vertical line meets a horizontal line below that ends at rays next to an illustration of a ray and meets a

horizontal line above that meets a vertical line. This vertical line meets a horizontal line above to sharks next to an illustration of a shark and a horizontal line below to bony fish next to an illustration of a bony fish.

Return to Figure 46.16 Correct and incorrect phylogenetic trees of sharks, rays, and bony fish

Extended description for: Figure 46.17 Varying rates of evolution in different groups

The tree begins with a short horizontal line on the left that meets a vertical line. This vertical line meets a horizontal line below that has two red vertical lines near its left and right ends and ends at bony fish next to an illustration of a bony fish. The vertical

line also meets a horizontal line above that meets a vertical line. This upper horizontal line has two evenly spaced red vertical lines, and one of these lines is labeled as New morphological trait. The vertical line meets a horizontal line above that has a single red vertical line almost halfway across and that ends at sharks next to an illustration of a shark, and it meets a horizontal line below with seven evenly spaced red vertical lines to end at rays next to an illustration of a ray.

Return to Figure 46.17 Varying rates of evolution in different groups

Extended description for: A phylogenetic tree shows the relationship between H I V samples from a dentist, patients, and random individuals with an African strain as an outgroup

A vertical line at the left meets a bottom horizontal line to H I V E L I, the outgroup, and an upper horizontal line branches to upper and lower horizontal lines that each branch in complex ways. Of these first two major branches, the lower horizontal line branches to upper and

lower horizontal lines. The upper horizontal line branches above and below to Patient D 1 and Patient D 2, respectively, and the lower horizontal line branches to L P 0 3 space 2 above and a horizontal line below that branches above and below to Patient F 1 and Patient F 2, respectively. Of the first two major branches, the upper line branches to horizontal lines above and below. The upper line leads to a complex series of branches that all end with highlighted labels, and the lower horizontal line branches to a horizontal line below to L P 0 2 space 2 and a horizontal line above that branches above and below to L P 0 2 space 1 and L P 0 3 space 1, respectively. The horizontal line that

leads to the highlighted groups branches to three horizontal lines. Of these three lines, the top horizontal line ends at Dentist 1. The middle horizontal line branches to three horizontal lines: an upper line that branches above and below to Patient B 1 and Patient B 2, respectively; a middle line that meets Patient A 1; and a bottom line that branches above and below to Patient E 1 and Patient E 2, respectively. Of the three lines to the highlighted groups, the bottom one branches to a lower horizontal line to Patient G 2 and an upper horizontal line that branches to Patient G 1 below and an upper horizontal line branches to Patient A 2 below and an upper horizontal line

that branches to Dentist 2 above and a lower horizontal line that branches to upper and lower horizontal lines to Patient C 1 and Patient C 2, respectively.

Return to A phylogenetic tree shows the relationship between H I V samples from a dentist, patients, and random individuals with an African strain as an outgroup

Extended description for: A four-part figure shows four different phylogenetic trees labeled a through d

Part a has a horizontal line at the bottom that meets a vertical line on

the right that ends at M and a vertical line on the left that meets a horizontal line. This horizontal line meets a vertical line on the right to L and a vertical line on the left to a horizontal line that meets a vertical line on the right to K and a vertical line on the left to J.

Part b begins at a bottom point from which lines extend diagonally up to the left and right. The right-hand line ends at M, and the left-hand line ends at L. Just before halfway up the line that ends at L, a diagonal line to the right branches to a diagonal line to J to the left before ending at K.

Part c begins with a vertical line at

the left that meets a horizontal line below that ends at M and a horizontal line above that ends at a vertical line that meets a horizontal line to L below and a horizontal line above that meets a vertical line that meets a horizontal line to K above and a horizontal line to J below.

Part d begins on the left with a point from which diagonal lines extend to L at the upper right and M at the lower right. The line to L has two branches that extend to the lower right. The first branch ends at K, and the second branch ends at J.

Return to A four-part figure shows four different phylogenetic trees

labeled a through d

Extended description for: A phylogenetic tree shows evolutionary relationships of italic Ceratitis capitata end italics by location

The phylogenetic tree begins at the left with a point from which diagonal lines extend to the upper and lower right. The line to the lower right ends

at Mediterranean (2000) and branches just before its end to Australia (2002). The line to the upper right branches halfway along. The upper branch ends at Mediterranean (1994) just after it branches to Mediterranean (1994). The lower branch itself branches about halfway along to a line to Australia (1994) to the lower right and a line that ends at Hawaii (1992) to the upper right just after branching to South Africa (2001) below.

Extended description for: A phylogenetic tree shows the relationships between seven species labeled J through P

Morris, et al., *Biology for the AP® Course, 1e,*
© 2022 BFW High School Publishers

The phylogenetic tree begins at a point on the left from which a

diagonal line extends up to Species J at the upper right and a diagonal line extends down to Species P at the lower right. Four diagonal lines branch upwards from the bottom line to species P. The first of these lines branches near the start of the tree and extends upward to Species K with a branch at about one-third of its length to Species L. The second of the branches ends at Species M. The third branch ends at Species N. The fourth branch ends at Species O.

Return to A phylogenetic tree shows the relationships between seven species labeled J through P

Extended description for: A phylogenetic tree shows evolutionary relationships among major plant groups along a timeline

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A timeline beneath the phylogeny is labeled “Millions of years ago” and

runs from before 600 to 0, in major increments of 100 and minor increments of 50. A box indicates that letters represent key traits as follows: A: vascularization, B: seeds for reproduction, C: lateral sporangia, D: flowers for reproduction, E: reticulate leaf venation. The tree begins with a vertical line at 625 that meets a horizontal line below that ends at Mosses at 0 and that meets a horizontal line above that runs through a point labeled A at 450 before meeting a vertical line at 440. This vertical line meets a lower horizontal line that runs through a point labeled C at 280 to end at Lycophytes at 0 and an upper horizontal line that meets a vertical

line at 390. This vertical line meets a horizontal line below that ends at Ferns at 0 and a horizontal line above that runs through a point labeled B at 360 to meet a vertical line at 325. This vertical line meets a lower horizontal line that ends at Gymnospherms at 0 and an upper horizontal line that runs through a point at 200 to meet a vertical line at 140. This vertical line meets a horizontal line below that ends at Monocots at 0 and a horizontal line above that runs through a point labeled E at 70 to end at Dicots at 0.

Extended description for: Figure 47.4 Three species of Agrodiaetus butterflies

Photos: Vladimir Lukhtanov, Zoological Institute of Russian Academy of Sciences, St. Petersburg, Russia
Morris, et al., *Biology for the AP * Course*, 1e, © 2022 BFW High School Publishers

Three photos of butterflies are lined

up in a vertical pattern. To the right of each photo is a horizontal arrow pointing to a circular pattern of stained chromosomes. Each chromosome pattern is slightly different, with the middle having the largest and fewest chromosomes, followed by the bottom pattern with the next largest and greater chromosome count. The top pattern has the smallest chromosomes with the highest count. Text above the illustrations reads, “This microscopic view of stained chromosomes reveals that the three butterflies have different numbers of chromosomes.”

Return to Figure 47.4 Three species of Agrodiaetus butterflies

Extended description for: Figure 47.6 Speciation, the process by which one species becomes two species

Morris, et al., *Biology for the AP® Course, 1e*, © 2022 BFW High School Publishers

An arrow labeled time points downward at the left side of the

illustration. At the top, an oval of diagonal lines running from upper left to lower right has a dashed line running in a jagged vertical pattern through its center. Accompanying text reads, “A single interbreeding population is split into two populations.” Arrows point down to the lower right and left, with the left-hand arrow pointing to an illustration showing the left half of the oblong above and the right-hand arrow pointing to an illustration of the right half of the oblong above. The left-hand patch has an arrow pointing downwards to the left with five unevenly spaced horizontal lines labeled mutations. The arrow becomes purple near the arrowhead.

It indicates a patch resembling the left-hand starting patch but purple. The right-hand patch has an arrow pointing downward to the right with four unevenly spaced mutations in its first half before it turns green, where it has an additional two mutations before it ends with a green arrowhead. This arrow indicates a patch resembling the right-hand starting patch but green. Three arrows point right from the left-hand arrow to meet arrows pointing left from the right-hand arrow. The first two pairs of arrows have checkmarks between them, and the bottom pair of arrow has an X between them. A key indicates that a checkmark means that the populations are able to

interbreed and an X means that the populations are unable to interbreed. Accompanying text aligned with the first two pairs of arrows with checkmarks reads, “At first, individuals from each population will still be able to interbreed.” Accompanying text aligned with the bottom pair of arrows with the X reads, “Speciation occurs when the two populations are no longer able to produce viable, fertile offspring.” Text to the left of the set of arrows reads, “The two populations diverge genetically because different mutations occur and become fixed in each population over time.” A double-headed arrow pointing to the left and right beneath the pair of new

populations is labeled genetic difference.

Return to Figure 47.6 Speciation, the process by which one species becomes two species

Extended description for: Figure 47.7 Allopatric speciation by dispersal

A small inset map shows Australia and New Guinea with an arrow pointing from New Guinea to an enlarged view of New Guinea marked with eight different colors to represent the subspecies. The region at the northwest is marked in yellow,

with a small patch of purple over an island to the west of its northern end and a small patch of purple over an island to the east of its central region just west of a larger blue patch over a larger island. A horizontal region along the northern coast of New Guinea is orange, and a horizontal region along its southern coast but extending up into the center is red. This red region extends around a peninsula to the southeast and runs back along its northern coast, but the center of the peninsula is not colored. There is a small green spot over an island north of the eastern part of the orange region and a small pink spot over an island to the southeast of the map. An illustration shows a blue bird

perched on a branch. The bird has a sharp, pointed beak and a long tail. Accompanying text reads, “Mainland subspecies of italic Tanysiptera galatea end italics are similar to one another, but island subspecies are more distinct, suggesting faster genetic divergence on island populations” and “The eight subspecies on New Guinea and nearby islands are marked in different colors.”

Return to Figure 47.7 Allopatric speciation by dispersal

Extended description for: Figure 47.8 Darwin's finches

The tree begins with a short horizontal line labeled ancestor from

South America mainland. A photo shows a bird with a tan head and short beak. The horizontal line meets a vertical line that branches above and below. The lower branch also branches above and below to purple highlighted green warbler finch (italic Certhidea olivacea end italics) and purple highlighted Gray warbler finch (italic C. fusca end italics), respectively. A photo shows a darker finch head with a small, thin beak. The upper branch from the ancestor has branches above and below that lead to two main groups of birds, an upper blue group and a lower green and purple group. The lower line branches above to green highlighted vegetarian finch (italic Platyspiza

crassiostris end italics) next to an image of a bird with a gray head and a triangular beak, and it branches below to a horizontal line below that further branches above and below to lines that each further branch to the remaining two purple highlighted groups. The lower horizontal line branches above and below to mangrove finch (italic C. heliobates end italics) and woodpecker finch (italic C. pallidus end italics), respectively. The upper head is gray with a gray beak, and the lower head is tan with a curved tan beak. The upper horizontal branch of the purple group branches above to small tree finch (italic Camarhynchus parvulus end italics) next to a small tan head

with a small triangular beak and to a horizontal line below that branches above and below to large tree finch (italic C. psittacula end italics) and medium tree finch (italic C. pauper end italics), respectively. The large tree finch is tan, and the medium tree finch is gray, both with orange beaks. Going back to the upper branch from the ancestor, the upper horizontal line to the blue-highlighted species branches to three horizontal lines: top, middle, and bottom. The bottom horizontal line branches above and below to Española cactus finch (italic G. scandens end italics) and common cactus finch (italic G. scandens end italics), respectively. These are both brown birds with orange beaks with

the Española cactus finch having a small eye and thicker beak. The middle line ends at sharp-beaked ground finch (italic G. difficilis end italics), which has a brown head and pointed orange beak. The top line branches to a horizontal line below to large ground finch (italic G. magnirostrise end italics) and a horizontal line above that further branches above and below to small ground finch (italic Geospiza fuliginosa end italics) and medium ground finch (italic G. fortis), respectively. The large ground finch is light brown with an orange beak. The medium ground finch has a small eye, dark grayish brown feathers, and a dark orange beak. The small ground

finch has a brown head and orange triangular beak. Text accompanying the blue highlighted groups reads, blue highlighted Seed-eaters end highlight, “The finches on this branch of the tree have bills adapted for picking and crushing different-sized seeds.” Text accompanying the green highlighted vegetarian finch reads, green highlighted Bud-eater end highlight, “Only one finch species evolved with adaptations for pulling buds off trees.” Text accompanying the purple highlighted groups reads, purple highlighted Insect-eaters end highlight, “Several species of finch evolved with differently shaped bills adapted to eating different kinds of insects.” All of the finches have

slightly different beaks reflecting their specializations.

Return to Figure 47.8 Darwin's finches

Extended description for: Figure 47.9 Graph of number of islands and number of species over time

Morris, et al., *Biology for the AP® Course, 1e,*
© 2022 BFW High School Publishers

The horizontal axis is labeled millions of years ago and ranges from 5 to 0, in decrements of 1. The vertical axis is labeled numbers and ranges from 0 to 20, in increments of 5. There are two

curves on the graph. The curve for number of islands begins with a slight increase, runs horizontally to 1.9 million years ago, then rises rapidly before leveling off at (0.6, 18). The curve for the number of finch species begins at (3, 1) and rises with a slight concave-up shape before leveling off at (0.4, 13.5). The data from the graph are as follows. Number of islands: (4.5, 1), (4.3, 2), (4.1, 3), (3.4, 4), (1.4, 5), (1.1, 6), (1.1, 7), (0.6, 8), (0.65, 9), (0.6, 19), (0.6, 11), (0.6, 12), (0.6, 13), (0.6, 14), (0.6, 15), (0.6, 17), (0.6, 18), (0.6, 19), and (0, 19). Number of finches: (3, 1), (2.86, 2), (1.8, 3), (2.2, 5), (0.7, 7), (0.55, 8), (0.45, 9), (0.4, 10), (0.4, 11), (0.4, 12), (0.4, 13), and (0, 14). The curve for number of species runs

below the curve for number of islands and roughly approximates its shape. All data are approximate. Accompanying text reads, “The number of species increased as more islands appeared, suggesting that allopatric isolation of populations on different islands was important for speciation in these birds.”

Return to Figure 47.9 Graph of number of islands and number of species over time

Extended description for: Two maps show how the Eastern Pacific and Caribbean populations of italic Alpheus end italics were separated when land came together

Morris, et al., *Biology for the AP® Course, 1e*, © 2022 BFW High School Publishers

The first map shows the Eastern Pacific and Caribbean populations of

italic Alpheus end italics at 3.5 million years ago. Land and shallow water are marked on the map. A double-headed arrow points between the shallows water between present-day Nicaragua and Costa Rica. A double-headed arrow points between the oceans across shallow water in present-day Panama. An arrow points from shallow water of the region where present-day Columbia and Panama meet to ocean to the northeast, northwest, and southwest. Accompanying text reads, “Interbreeding between eastern Pacific and Caribbean populations was possible via the corridors that existed before the final formation of the Isthmus of Panama.” Eastern

Pacific population is marked on the left of the landmass and Caribbean population on the right.

The second map shows the Eastern Pacific and Caribbean populations of italic Alpheus end italics today. The map is labeled to show Nicaragua at the northern edge with Costa Rica to the south curving to meet Panama. Panama curves from the northwest then runs almost horizontally before curving southeast to meet the northwest edge of Columbia. The Eastern Pacific population is shown in the Pacific Ocean to the west completely separated by land from the Caribbean population in the Caribbean Sea to the east.

Accompanying text reads, “Interbreeding between eastern Pacific and Caribbean populations is no longer possible because of the geographic barrier.”

Return to Two maps show how the Eastern Pacific and Caribbean populations of italic Alpheus end italics were separated when land came together

Extended description for: A figure shows a phylogenetic tree of species of italic Alpheus end italics

A photo shows a species of italic Alpheus end italics, which is a shrimp that resembles a lobster and has large claws. Accompanying text reads, “The

closing of marine corridors resulted over time in the speciation of italic Alpheus end italics into Eastern Pacific and Caribbean species." The phylogenetic tree shows 17 species of Alpheus. A vertical line on the left side of the tree meets three horizontal lines: top, middle, and bottom. The bottom horizontal line ends at blue highlighted Caribbean 7. The middle line meets a vertical line at a circular node, and this vertical line meets upper and lower horizontal lines labeled red highlighted Pacific 7 prime and Pacific 7, respectively. The top line branches to horizontal lines above and below with the top horizontal line leading by various branches to species 3 through 6 and

the bottom line branching to species 1 and 2. The bottom horizontal line branches to horizontal lines above and below. The upper horizontal line branches at a node to red highlighted Pacific 1 above and blue highlighted Caribbean 1 below. The lower horizontal line branches at a node to red highlighted Pacific 2 above and blue highlighted Caribbean 2 below. Going back to the vertical line that separates species 1 and 2 from species 3 to 6, the upper line branches to horizontal lines above and below. The upper horizontal line branches to red highlighted Pacific 6 prime above and to a horizontal line below that branches at a node to horizontal lines above and below to red highlighted

Pacific 6 and blue highlighted Caribbean 6, respectively. Going back to the vertical line with the upper horizontal line to these three groups labeled 6 and 6 prime, the bottom horizontal line branches to species labeled 3 above and species labeled 4 and 5 below. The lower branch also branches at a node to blue highlighted Caribbean 4 above and red highlighted Pacific 4 below. The horizontal line above also branches to horizontal lines above and below. The bottom of these horizontal lines branches at a yellow node to red highlighted Pacific 5 above and blue highlighted Caribbean 5 below. The upper horizontal line branches to blue highlighted Caribbean 3 prime

below and to a horizontal line above that branches at a node to red highlighted Pacific 5 above and blue highlighted Caribbean 5 below.

Return to A figure shows a phylogenetic tree of species of italic Alpheus end italics

Extended description for: Figure 47.10 Sympatric speciation by disruptive selection

Both graphs have a horizontal axis labeled bill size that ranges from small on the left to large on the right and a vertical axis labeled number of

individuals. The upper graph has a curve with two smooth peaks. The left-hand part of the curve is enclosed by a bracket that is symmetrical around its peak and labeled small-seed specialist. The right-hand part of the curve is enclosed by a similar bracket that is symmetrical around its peak and labeled large-seed specialist. A double-headed arrow between the peaks reads natural selection. Accompanying text reads, “Natural selection eliminates medium-billed birds in an environment with no medium-sized seeds, and favors small billed birds and large billed birds in response to the availability of small and large seeds.”

An arrow from the first graph points down to the second graph. The second graph shows a peak far to the left and a peak far to the right. Accompanying text read, “Disruptive selection, if strong enough and sustained enough, may eventually lead to sympatric speciation.”

Return to Figure 47.10 Sympatric speciation by disruptive selection

Extended description for: Figure 47.11 Speciation by hybridization in sunflowers

Photos: (top left) Gary A. Monroe, hosted by the USDA-NRCS PLANTS Database; (top right) Jason Rick; (bottom) Gerald J. Seiler, USDA-ARS

Italic Helianthus annus end italics is a plant with flowers that have a dark circular center surrounded by yellow petals, giving each flower an overall

circular shape. The flowers extend above the leaves on long stems. Italicized Helianthus petiolaris end italics is similar but appears bushier with slightly lighter colored flowers. These are crossed, and an arrow points down to show italic Helianthus anomalus end italics, which has similar flowers and dense leaves with some longer stems like italic Helianthus annus end italics.

Return to Figure 47.11 Speciation by hybridization in sunflowers

Extended description for: Figure 47.12 Speciation by hybridization in Darwin's finches

A bar that is pointed on its right side is divided into three parts labeled from left to right as Generation 1, Generation 2, and Generation 3. In generation 1, italic G. fortis end

italics, Resident on Daphne Major, is depicted as a gray bird with a triangular orange beak. A line extends down to a black finch head with a more rounded triangular beak that is black on top and yellow beneath. A vertical line connects the two and meets a horizontal line that branches to horizontal lines to a hybrid female above and a hybrid male below in generation 2. The female has a brown head and light orange beak with light brown at the top, and the male is darker brown with a gray beak. A vertical line connects the hybrids and meets a horizontal line labeled inbreeding that extends to a new hybrid species in generation 3. This new species is

very dark brown to black with a gray beak that is rounded and triangular.

Return to Figure 47.12 Speciation by hybridization in Darwin's finches

Extended description for: A graph shows the number of generations produced by two types of European corn borer moths per year

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The graph has a horizontal axis labeled from left to right as June, July, and August and a vertical axis labeled number of adult E C B moths. A solid curve representing univoltine begins

midway between June and July and forms a peak at three-quarters of the vertical axis that descends to meet the horizontal axis closer to the July label than the August label. A dashed curve representing bivoltine begins near the left end of the horizontal axis and forms a peak at half the height of the vertical axis in June that ends as the solid curve begins midway between June and July. The dashed curve begins again at the end of the solid curve between July and August and forms a similar but slightly wider peak in early August at half the height of the vertical axis. This curve descends to reach the horizontal axis near its right end.

Return to A graph shows the number of generations produced by two types of European corn borer moths per year

Extended description for: A visual synthesis titled speciation shows genetic drift. A visual synthesis titled speciation shows natural selection

An illustration shows a parental population of a square of fish icons at the top right with an arrow pointing to daughter population A to the lower

left and another arrow pointing to the right to a line that extends out of the frame. The parent population consists of ten columns and four rows of mostly gray fish with three red fish scattered among them, and a line shows an enlarged gray fish in a circle. Text next to this fish reads, “1. Different mutations arise in each population. Some (red) are deleterious and are eliminated by selection. Some (green) are advantageous and swept to fixation (100 percent frequency) by selection. Some (blue) are neutral, so their fate is governed by genetic drift, and they ultimately drift to either extinction or fixation.” An arrow labeled time begins at the past next to the parent

population and points to text at the lower left reading, present. Horizontal rows of fish in daughter population A beside the time arrow represent generations. The first row is entirely gray. The second row has one red fish. As the generations continue, there are occasional red fish, and then a blue fish appears in generation ten. A line points from this blue fish to a blue circle labeled change in pigment. Text reads, “A neutral mutation that briefly drifts up in frequency before drifting to extinction.” A fish with a green back is depicted next to a graph. The horizontal axis is labeled generations with an arrow pointing to the right. The vertical axis ranges from 0.0 to

1.0 in increments of 0.2. A curve begins just above (0, 0.0) and rises in a jagged way to form a couple of small peaks below 0.2 before meeting the horizontal axis just before its midpoint. It then runs horizontally along the horizontal axis. Generations 10 through 21 each contain some blue fish, which increase in number through time, and a few red fish are present across all of these generation. A line points from a blue fish in generation 15 to a blue circle labeled change in pigment that shows a fish with a blue back and a graph. Text reads, “A neutral mutation that drifts to fixation.” The horizontal axis of the graph is labeled generations with an arrow pointing to the right. The

vertical axis ranges from 0.0 to 1.0 in increments of 0.2. A jagged curve begins at (0, 0.0) and stays low at first, the rises rapidly to the left of the midline to peak at 0.65, runs in a jagged horizontal pattern briefly, and then rises to meet and run along the top of the graph starting at two-thirds of the length of the horizontal axis. Accompanying text reads, “Because neutral mutations, like these that change fish coloration, do not affect fitness, their frequencies vary from generation to generation by chance alone. In small populations, these shifts in frequency can be extreme. If this process runs for long enough, neutral mutations eventually drift to extinction (0 percent) or fixation (100

percent).” Generation 21 is highlighted and contains six gray fish, one red fish, and three blue fish. An arrow pointing to this row reads, “1 fixed difference between populations.” Text above reads, “A fixed difference occurs when the frequency of an allele reaches 100 percent. Here, a fixed difference is shown when an entire row is green or blue.” The pattern continues with increasing numbers of blue fish per generation but a relatively constant frequency of occasional red fish. Row 30 is highlighted and contains entirely blue fish. An arrow pointing to this row reads, “2 fixed differences between the populations.” Text above reads, “There are two fixed

differences between the populations. The fish in population B are all larger than the fish in population A, and they lack the distinct pigmentation of the fish in population A." Two more generations are depicted. All data are approximate.

An arrow points from the upper left to Daughter population B. This consists of rows of ten fish each with each row representing a generation. Most of the fish are gray at first, with the occasional red fish. A key defines the colors as follows. Red fish: A deleterious mutation decreases the fitness of the organism. Blue fish: A neutral mutation does not affect the fitness of the organism. Green fish: A

beneficial mutation increases the fitness of an organism. Text to the left reads, “Allopatric speciation: When two populations are separated by a geographic boundary, they diverge genetically over time and eventually become reproductively isolated.” A line pointing to a red fish leads to a red arrow showing a fish with fins that stick out a great deal. Text reads, “Less streamlined fin shape, a deleterious mutation that is eliminated by natural selection.” Blue fish begin to appear in generation 4, and one is present in each of generations 4, 5, 6, and 8. Two blue fish are present in generation 7. A line from the first blue fish leads to a blue circle with text reading, “Change

in pigment: A neutral mutation that briefly drifts up in frequency before drifting to extinction." A picture of a fish with colorful patches is accompanied by a graph. The horizontal axis is labeled generations with an arrow pointing to the right. The vertical axis ranges from 0.0 to 1.0 in increments of 0.2. A curve begins just above (0, 0.0) and rises in a jagged way to form a couple of small peaks below 0.2 before meeting the horizontal axis just before its midpoint. It then runs horizontally along the horizontal axis. Green fish first appear in generation 14 and increase in subsequent generations with only one exception, a decrease in generation 20. A line points from

the first green fish to a green circle with an illustration of a large fish. Accompanying text reads, “Larger mass: A beneficial mutation driven to fixation by natural selection.” A graph is also present below it. The horizontal axis is labeled generations and points to the right. The vertical axis ranges from 0.0 to 1.0, labeled in increments of 0.4. A curve begins at 0.0 and rises rapidly on the left side of the graph to approach the top of the graph by one-third of the length of the horizontal axis and then runs horizontally just under the top of the vertical axis from just before the midpoint of the horizontal axis. Accompanying text reads, “Fish with the mutation are larger than fish

without it. Because large size is advantageous in this environment, larger fish are more likely to survive and reproduce than smaller fish. The frequency of the mutation in the population therefore increases over time by natural selection. This process continues until the mutation is fixed and all the fish in the population are large." In generation 21, all of the fish are green. This row is highlighted. An arrow points to this row from the left. Text below reads, "2. Mutations may be fixed by selection or drift in both populations. Different mutations are fixed in each population. Through time the populations diverge genetically." Additional generations after

generation 21 are depicted with occasional red fish present. An arrow points right to generation 30. Text at the bottom of the column of fish representing the generations reads, “3. Eventually, the two populations become so genetically divergent through the accumulation of fixed differences that mating between individuals of different populations fails to produce viable, fertile offspring. Speciation has occurred.” All data are approximate.

Return to A visual synthesis titled speciation shows genetic drift. A visual synthesis titled speciation shows natural selection

Extended description for: Figure 48.1 Birds, crocodiles, and their extinct relatives

A bar beneath the tree is labeled with a scale representing millions of years ago (m y a) ranging from before 240 m y a to 0, the present time. The tree

begins with a horizontal line at the upper left representing the root. This line meets a vertical line at 240 m y a that meets a long horizontal line above that extends to crocodiles at 0 (the present time) and a short horizontal line below that meets a vertical line at 239 m y a. This vertical line meets a horizontal line above that extends to Ornithischian dinosaurs at 73 m y a and a short horizontal line below labeled with a circle midway along indicating the appearance of four digits in hands at 235 m y a. This short horizontal line meets a vertical line at 230 m y a that meets a horizontal line above to Eoraptor at 210 m y a and a short horizontal line below to a vertical line

at 220 m y a. This vertical line meets a horizontal line above to Coelophysoids at 175 m y a and a horizontal line below to a vertical line at 205 m y a. This vertical line meets a horizontal line above to Allosaurids at 90 m y a and a very short horizontal line below labeled with a circle indicating the appearance of hollow cylindrical feathers at 195 m y a that meets a vertical line at 195 m y a. This vertical line meets a horizontal line above to Comsognathids at 110 m y a and a short horizontal line below labeled with a circle indicating the appearance of tufted feathers at 200 m y a before it meets a vertical line at 195 m y a. This vertical line meets a horizontal line above to the

Tyrannosauroids at 70 m y a and a short horizontal line below that meets a vertical line at 189 m y a. This vertical line meets a horizontal line above to Dromaeosaurids at 70 m y a and a horizontal line below with a circle at its midpoint indicating the appearance of feathers closed and asymmetrical at 179 m y a. This horizontal line meets a vertical line at 173 m y a that meets a horizontal line above to Oviraptorosaurs at 70 m y a and a short horizontal line below labeled with a circle to indicate the appearance of long arms at 168 m y a. This horizontal line meets a vertical line at 168 m y a that meets a horizontal line above to Archaeopteryx at 149 m y a and a

horizontal line below that extends to living birds at 0, the present. On the horizontal line to birds, there is a circle near its left end indicating the appearance of a toothless beak, fused wing digits, and short feathered tail at 178 m y a. Each group name is accompanied by an illustration. Crocodiles are accompanied by an illustration of a crocodile. Ornithischian dinosaurs is accompanied by an illustration of a thick-bodied dinosaur with two horns and a shield extending up above its neck that walks on four legs and has a tail that is very thick and roughly triangular at its base before narrowing. Eoraptor is depicted as a thin dinosaur standing on two thin

legs with short forelimbs and both its head and tail raised. Coelophysoids are depicted as a thin dinosaur with short arms standing on two legs. It has a long thin neck to a narrow head. Allosaurids are depicted as a thickset dinosaur standing on two legs and with short arms. Compsognathids are depicted as a thin dinosaur standing on two legs but bent forward. It has short arms, a very long tail, and a thin head. Tyrannosauroids are depicted as a very heavyset dinosaur with short arms standing on two legs with muscular upper portions and with a large head. Dromaeosaurids are depicted as a dinosaur standing on two legs with a flat back extending to

a long tail and with a long head. Oviraptorosaurs are depicted as a dinosaur standing on two legs with a rounded back, relatively long arms, and small head with a crest. Arcaheopteryx is depicted as a dinosaur with feathers on long arms extending forward, along all of its tail except the part near its base, and on legs that lead to feet without large feathers. Living birds are depicted using an illustration of a hawk. All data are approximate.

Return to Figure 48.1 Birds, crocodiles, and their extinct relatives

Extended description for: Figure 48.3 Mass extinctions

Morris, et al., *Biology for the AP* Course*, 1e, © 2022 BFW High School Publishers

The horizontal axis is labeled millions of years ago and ranges from before 500 millions of years ago (m y a) to the present, in major increments of 200

and minor increments of 100. The vertical axis is labeled number of animal genera and ranges from 0 to 2500, in increments of 500. Time periods are depicted at the top of the graph as follows: Cambrian 540 to 490 m y a, Ordovician 490 to 440 m y a, Silurian 440 to 410 m y a, Devonian 410 to 370 m y a, Carboniferous 370 to 295 m y a, Permian 295 to 250 m y a, Triassic 250 to 205 m y a, Jurassic 205 to 150 m y a, Cretaceous 105 to 75 m y a, Paleogene 75 to 30 m y a, and Neogene 30 m y a to present. A curve on the graph begins at (540, 0) and rises to (520, 500), then drops slightly and moves up and down horizontally at 470 on the vertical axis until it begins to rise at (480, 470) to reach a

jagged peak at (440, 1400). It then drops rapidly beneath a downward pointing arrow at 440 m y a during the Silurian Period. It rises in a jagged way to peak at (290, 1550), then descends rapidly to two minimums close together beneath a downward pointing arrow at 380 m y a at the start of the Carboniferous Period. The curve rises to peak at (325, 1350), drops to (310, 1000) to run in a jagged horizontal pattern for a short distance, rises to (250, 1250), then decreases to (252, 350) beneath a downward-pointing arrow at the end of the Permian Period and start of the Triassic Period. A line leads from this point to text reading, “The largest mass extinction occurred 252 million

years ago at the end of the Permian period." The curve rises to (210, 750), then drops to (201, 499) beneath a downward-pointing arrow near the start of the Jurassic Period. The curve increases in a jagged manner until (70, 2250), then descends rapidly to (65, 1350). A line pointing to this point is accompanied by text reading, "The mass extinction at the end of the Cretaceous Period eliminated dinosaurs (except birds) and made way for the Age of Mammals." The curve rises rapidly in a jagged manner to end at (0, 2500) just after its highest peak in the Neogene. All data are approximate.

Return to Figure 48.3 Mass

extinctions

Extended description for: A photo of a striated rock is depicted next to a graph that shows how much iridium in parts per billion can be found in certain different layers of rock from the Paleogene and Cretaceous Periods

An arrow points toward a layer in a rock that is noticeably lighter in color than the other layers because it

contains a substantially higher concentration of iridium than the other layers. Text accompanying this arrow reads: “Iridium, common in meteorites, was discovered in rock layers corresponding to the time of extinction.” This layer, as noted by the graph, marks the period between the end of the Cretaceous period and the beginning of the Paleogene. There are layers of brown to gray rocks above and below and a Swiss Army knife placed vertically from the iridium layer to the bottom of the photo to illustrate scale.

The horizontal axis of the graph is labeled amount of Iridium in rock layers (parts per billion) and ranges

from 0 to 4, in increments of 0.5. The left-hand vertical axis is labeled Depth (meter) and ranges from 286 to 274, in increments of 2. The right-hand vertical axis of the graph shows the depths from 286 to 280 are Cretaceous and depths from 280 to 274 are Paleogene. A line connects numerous points representing the amount of iridium in samples taken at certain depths. The amount in the samples fluctuates fairly steadily between 0 and 0.65 parts per billion as the samples get deeper until a depth of just above 280 meters, at which point the amount of iridium increases rapidly to a point at (3.65, 280) before decreasing rapidly to (0.25, 280.8) and then resuming a

similar pattern to its pattern above this region of anomalously high iridium sample until it ends at (0, 284.3). All data are approximate.

Return to A photo of a striated rock is depicted next to a graph that shows how much iridium in parts per billion can be found in certain different layers of rock from the Paleogene and Cretaceous Periods

Extended description for: A photo shows a striated structure quartz crystal, an example of shocked quartz, above a map of Central America along with a satellite image of a crater where this type of quartz is found

The quartz has many horizontal lines

and a range of bright colors. Accompanying text reads, “Quartz crystals that form only at high temperature and pressure dash conditions met by giant meteors as they crash into Earth dash occur abundantly in rock layers dated to the time of the extinction.” Below, a map shows Mexico with the Yucatán peninsula extending to the northeast. A box indicates a square region at northwest of the northern tip of the peninsula with an arrow showing a crater in this area. Text accompanying the map reads, “By 1990, geologists had located a crater of just the right age and size in the Yucatán Peninsula of Mexico.” The satellite image of the crater contains

many bright colors with a rounded crater in purple in the center that has a curved part to its left that meets a part that extends downward. A blue circle inside the crater extends up to a green region above bounded by light blue that meets a band of yellow to the left with a large, red, roughly triangular region to its left. Much of the surrounding area is dark blue to slightly purple except for a light green to blue region along the western side and a region of green with some yellow and a tiny bit of red to the east. Additionally, there is a red area in the lower right corner with bands of yellow, then green, then light blue before it reaches a blue and purple region.

Return to A photo shows a striated structure quartz crystal, an example of shocked quartz, above a map of Central America along with a satellite image of a crater where this type of quartz is found

Extended description for: Figure 48.4 The supercontinent Pangaea

Photo: Pangea from © Global Paleogeography and Tectonics © 2016 Colorado Plateau Geosystems Inc

The illustration shows a large, irregular, somewhat vertical land mass across the center of a globe with large amounts of water on each side and a few islands. The land is bordered by lighter blue, and there are patches of white above the land to the south, with an entirely white area

at the very bottom. There is a relatively large landmass just above the main landmass, separated by a narrow light blue region, with a somewhat diagonal smaller island to the southeast. A few islands are to the north, east, and southeast of this island.

Return to Figure 48.4 The supercontinent Pangaea

Extended description for: Figure 48.5 Growth of the human population over time

The horizontal axis of the graph ranges from 10,000 B C E to 0 and is

labeled 10,000 B C E, 5000 B C E, year 1, 1000, and 2000. It is not to scale. The vertical axis ranges from 0 to 8 billion, in increments of 1 billion. The population begins near the horizontal axis at 10,000 B C E, and a line pointing to the location indicates that the population was 5 million. The population stays near or just above this level until just after 5000 B C E, when it begins to rise slightly. In year 1, the population is labeled as 250 million. The population slowly rises, then rises more rapidly before decreasing to form a slight bump that peaks at 1200, then rises dramatically from 300 million around 1700 and continues to increase almost vertically. Points are labeled along the

rapidly rising part of the graph. In 1800, the population reached 1 billion. Accompanying text reads, “It took more than 100,000 years for the human population to reach 1 billion.” Additional points are labeled as follows: 1930, 2 billion; 1960, 3 billion; 1975, 4 billion; 1987, 5 billion; 2000, 6 billion; 2018, approximately 7.7 billion; and 2020, 7.8 billion. Accompanying text reads, “Today, Earth supports more than 7.8 billion people.” All data are approximate.

Return to Figure 48.5 Growth of the human population over time

Extended description for: Figure 48.8 Biodiversity at risk

The graph has a vertical axis labeled from top to bottom with the categories mammals, birds, amphibians, sharks and rays, and reef corals. Each of these categories has a

bar extending to the right, and all of the bars end at the same location to the right next to an illustration. The left side of each bar indicates vulnerable populations, and the right side, colored differently, indicates endangered. For mammals, 25 percent are endangered, depicted next to a picture of a raccoon. For birds, 14 percent are endangered, depicted next to a bald eagle. For amphibians 40 percent are endangered, depicted next to a frog. For sharks and rays, 31 percent are endangered, depicted next to a shark. For reef corals, 33 percent are endangered, depicted next to a blue coral. All data are approximate.

Return to Figure 48.8 Biodiversity at risk

Extended description for: A graph plots deer population against year to show how the white-tailed deer population in the United State varies over time

The horizontal axis is labeled Year and ranges from 1600 to 2000, in increments of 50. The vertical axis is

labeled deer population (thousands) and ranges from 0 to 800, in increments of 100. A curve begins at (1600, 720) and runs almost horizontally, then begins to decline slightly and forms a diagonal toward the lower right at (1690, 690). Just after the start of the diagonal, an arrow points upward to a point at 1710 accompanied by text reading, “First widespread use of guns to hunt deer.” The curve bends upward at (1805, 500) and continues upward through a point indicated by an arrow accompanied by text reading, “Extensive deforestation to create farmland, and removal of deer predators.” The curve bends to form a downward diagonal beginning at

(1835, 550), which is indicated by an arrow accompanied by text reading, “Greatly increased human population density and intensive deer hunting.” The line runs diagonally down to meet the horizontal axis at (1910, 1), then runs along the horizontal axis past an arrow pointing to it at 1940 that is accompanied by text reading, “Introduction of hunting regulations to manage deer populations.” The curve begins to increase immediately, then begins to rise rapidly at (1949, 50) before leveling off at (1990, 805) and running horizontally to the right end of the horizontal axis. All data are approximate.

population against year to show how the white-tailed deer population in the United State varies over time

Extended description for: Figure 49.4 The spread of Ug99

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The affected region runs from South Africa along the eastern coast through Zimbabwe and Mozambique,

then through Tanzania and Rwanda to the west before forming a vertical connection inland to a wider region in Ethiopia that continues along the coast to the northwest and inland in Sudan and Egypt. To the east of Ethiopia, a patch is depicted in Yemen. There is also a patch in Iran to the northeast. There are two red dots at the southwest of South African and two in eastern South Africa; four red dots in Zimbabwe with two crossing the border into Mozambique; many red dots in Rwanda, northern Tanzania, Kenya, and Uganda; four red dots in central to western Ethiopia; four red dots in Eritrea with two extending into Ethiopia and two extending into

Sudan; one red dot in Sudan; three red dots in northeastern Egypt near the Mediterranean; two red dots in western Yemen; and two red dots spread apart vertically in northwestern Iran.

Return to Figure 49.4 The spread of Ug99

Extended description for: Figure 49.5 Centers of origin for crops

Morris, et al., *Biology for the AP® Course*, 1e. © 2022 BFW High School Publishers

Sorghum, wheat, and coffee were domesticated in eastern Africa, largely in Ethiopia but extending into Eritrea, Sudan, Kenya, Somalia, and Uganda. Cabbage, lettuce, olives, oats, and wheat were domesticated in areas along all sides of the Mediterranean

Sea. Wheat and barley were domesticated in an oval that includes eastern Iraq and Syria, eastern Turkey, and northwestern Iran. Grape, lentil, onion, and carrot were domesticated mainly in northern India, Pakistan, Afghanistan, China, and nearby countries. Citrus, chickpea, eggplant, cucumber, and sugarcane were domesticated in eastern India. Sugarcane, banana, and coconut were domesticated primarily in Indonesia, Malaysia, and Thailand. Rice, soybean, and apricot were largely domesticated in eastern China and Korea. Corn, bean, chocolate, and sweet potato were primarily domesticated in Mexico. Potato, tomato, and pumpkin were

largely domesticated in a vertical curved area extending from Columbia through Peru into Bolivia and northern Argentina. Potato and strawberry were domesticated in a vertical region in central Chile extending west into Argentina. Peanut, pineapple, and cassava were domesticated largely in Uruguay and the southernmost part of Brazil. All data are approximate.

Extended description for: A graph plots proportion surviving to metamorphosis against salinity level in an aquarium for tadpoles from high salinity and low salinity egg sources

The horizontal axis is labeled salinity level in aquarium with low salinity on the left and high salinity on the right. The vertical axis is labeled proportion surviving to metamorphosis and ranges from 0 to 1.0, in increments of 0.2. For low salinity, the proportion of tadpoles surviving to metamorphosis is 0.55 and 0.75 for tadpoles from high and low salinity egg sources,

respectively. For high salinity, the proportion of tadpoles surviving to metamorphosis is 0.85 and 0.45 for tadpoles from high and low salinity egg sources, respectively. All data are approximate.

Return to A graph plots proportion surviving to metamorphosis against salinity level in an aquarium for tadpoles from high salinity and low salinity egg sources

Extended description for: An illustration shows Stanley Miller’s apparatus designed to simulate Earth's early atmosphere

The layout of the experiment resembles a square structure made of glass tubing and circular chambers. Text to the lower left reads, “1. Water is heated to produce water vapor.” To

the right, a round flask above a Bunsen burner flame labeled heating source is three-quarters filled with bubbling water. The flask has a tube extending through a stopcock to the upper left. A tube extends vertically upward, and an arrow labeled direction of circulation points upward within it. At about three-quarters of the height of the tube, a short vertical tube extends left through a stopcock and is labeled, gas inlet, C H 4, N H 3. Accompanying text reads, “2. Water vapor moves up the tube where a valve introduces gases.” An arrow points up along the tube as it turns horizontally to the right, then an arrow points around the corner as the tube bends down vertically to reach a

spherical flask. A horizontal zigzag line in the flask is connected to wires to the left and right that forms a loop and meet as disks to the upper left of the flask above and below the word, electrodes. Text above the zigzag line reads, Spark. Text below the zigzag line reads, H 2 O, C H 4, N H 3, H 2. Text to the right reads, “3. In another chamber, the water vapor and gases are subjected to electrical sparks, which energize chemical reactions.” A tube extends down from the spherical flask through a cylindrical structure labeled condenser for cooling that has two horizontal tubes projecting to the right, one from the top and one from the bottom. An arrow points from cold water into the upper tube,

and an arrow points outward from the lower tube. Text to the right reads, “4. The gaseous products are cooled in a condenser, the water vapor turns back to liquid which contains any chemicals produced.” An arrow points down from above the condenser to the location below where the tube bends horizontally left. Just before the midpoint of the bottom of the apparatus, the tube bends down slightly and becomes red as it bends left to run horizontally and then bend upward to become clear again and bend horizontally to run back into the original spherical flask of water. A vertical tube extending from center of the reddish horizontal tube has a stopcock and is labeled,

Sampling valve. Text below reads, “5. A reddish residue builds up. It is sampled through a valve and analyzed.”

Extended description for: Four different phylogenetic trees labeled a through d show the relationships between Q, R, S, T, and U

Morris, et al., *Biology for the AP* ® *Course*, 1e, © 2022 BFW High School Publishers

Tree a begins at the top with diagonal

lines extending to the lower left to end at Q and to the lower right to end at U. The line to the lower left to Q branches to R just before it reaches Q. The line to the lower right to U has branches from its midpoint to S and from three-quarters of its length to T.

Tree b has a horizontal line at the lower right that meets a vertical line on the right that ends at R and a short vertical line on the left that meets a horizontal line. This horizontal line meets a vertical line to Q on the right and a short vertical line on the left that meets a horizontal line. This horizontal line meets a vertical line to S on the right and a short vertical line on the left that meets a horizontal

line. This horizontal line meets a vertical line on the right that ends at U and a vertical line on the left that ends at T.

Tree c begins at a point on the lower left with diagonal lines extending to the upper right to S and to the lower right to T. The line to the lower right branches to U just before reaching T. The line to the upper right to S branches from its midpoint to a line that ends at R just after branching to Q.

Tree d has a vertical line at the upper left that meets an upper horizontal line that ends at Q and a lower horizontal line that ends at a vertical

line that meets short horizontal lines above and below that each meet vertical lines. The upper vertical line meets a horizontal line above to R and a horizontal line below to S. The lower vertical line meets a horizontal line above to T and a horizontal line below to U.

Return to Four different phylogenetic trees labeled a through d show the relationships between Q, R, S, T, and U

Extended description for: Four phylogenetic trees labeled a through d show the relationships between species J, L, M, K, and N

Tree a has a vertical line at the left that meets horizontal lines above and below. The upper horizontal line meets a vertical line that meets a

horizontal line to species M below and a horizontal line above that meets a vertical line that meets a horizontal line above to species J and a horizontal line below to species L. The lower horizontal line attached to the original vertical line meets a vertical line that meets a horizontal line above to species K and a horizontal line below to species N.

Tree b has a vertical line at the lower left that meets a horizontal line to species N below and a horizontal line above to a vertical line that meets a horizontal line to species M below and a short horizontal line above that meets a vertical line. This vertical line meets a horizontal line below to

species K and a horizontal line above that meets a vertical line that meets a horizontal line to species L below and a horizontal line to species J above.

Tree c has a vertical line at the upper left that meets horizontal lines above and below. The upper horizontal line meets a vertical line that meets a horizontal line above to species L and a horizontal line below to species J. The lower horizontal line meets a vertical line that meets a horizontal line to species K above and that meets a horizontal line below that meets a vertical line that meets a horizontal line to species M above and a horizontal line to species N below.

Tree d has a vertical line the lower left that meets a horizontal line below to species N and a horizontal line above that meets a vertical line that meets horizontal lines above and below. The upper horizontal line meets a vertical line that meets a horizontal line above to species L and a horizontal line below to species J. The lower horizontal line meets a vertical line that meets a horizontal line to species K above and a horizontal line to species M below.

Extended description for: Figure 51.1 The hierarchy of ecological systems

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The levels in the hierarchy of ecological systems are depicted in circles that increase in size, arranged in a concave-down configuration from the lowest level at the lower left to the highest level at the lower right. At the lower left, a circle shows a

single white rabbit. The rabbit is sitting on snow with coniferous trees in the background. Accompanying text reads, “Individual, Survival and reproduction dash the unit of natural selection.” Just above and slightly to the right, a larger circle shows five rabbits on snow with coniferous trees in the background. Accompanying text reads, “Population, Population dynamics dash the unit of evolution.” Just above and to the right, a larger circle shows a rabbit standing on its hind legs on snow near a brown rodent. A narrow stream separates these animals from a large lynx sitting immediately behind a small lynx. There are snow-covered trees in the background. Accompanying text

reads, “Community, Interactions among species.” A larger circle to the right extending slightly lower shows a snowy scene with rocks in the foreground, a coniferous tree to the right, a coniferous forest in the midground, and snow-covered mountains in the background. Accompanying text reads, “Ecosystem, Flow of energy and matter.” A larger circle to the lower right shows the entire globe with North America at the front center, Greenland visible to the upper right, and Central and South American visible extending from the lower right center to the lower right side. Accompanying text reads, “Biosphere, Global processes.”

Return to Figure 51.1 The hierarchy of ecological systems

Extended description for: Figure 51.2 Phototropism in plants

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a. On the left, a short plant appears with a vertical stem that is highlighted from the center up to a small protrusion at the top representing the apical meristem.

Two small leaves extend from each side near the base of the stem, and two large leaves extend to the upper left and right from just below the apical meristem. Two parallel wavy arrows pointing down at the plant are labeled light from above. An arrow pointing down along the stem of the plant is labeled auxin. An arrow points right to show a similar illustration in which the plant has become taller. An upward-pointing arrow to the right of the stem is labeled plant growth. Accompanying text reads, “When the light source is directly overhead, the auxin moves evenly down the stem and the plant grows straight upward.”

Part b. A short plant is similar to the left-hand plant in part a except that the highlighting runs the full length of the stem, but only on the left side. Two diagonal wavy arrows extending from the upper right to point to the lower left above the plant. These wavy arrows are labeled light from the side. The arrow labeled auxin is now located above the plant and points to the left. Text below reads, “When light reaches the plant at an angle, auxin is redistributed to the shaded side of the shoot.” An arrow points right to a similar illustration except that the plant has become taller and has an upper half that bends toward the right. An arrow to the left of the plant labeled shoot growth runs vertically

at first and then bends to the right along the upper part of the plant. Text below reads, “Higher auxin concentration causes the shaded side to grow more rapidly, causing the stem to bend toward the light.”

Extended description for: Figure 51.6 Innate courtship behavior

Photo: BRUCE BEEHLER/AGE Fotostock

The male bird has a brownish body, black neck, yellow ring around its neck, yellow upper head, and black beak. He is standing up above the branch on which he is perched with his wings outstretched and his tail spread. His tail consists of many long feathers that form a wide curved structure that extends upwards and then curves downward. Between the male bird's body and tail, there is a similarly colored female bird facing away from the camera with her wing against her body and a relatively short, rectangular tail that looks very different from the tail of the male. Her head is barely visible behind the male's tail.

Extended description for: A graph plots average number of attempts to eat shrimp against time to illustrate the response of stickleback fish to the sight of brine shrimp in a glass tube that prevented the fish from eating the shrimp

The horizontal axis is labeled time (minutes) and ranges from 0 to 10, in increments of 1. The vertical axis is labeled average number of attempts to eat shrimp (l n plus 1) and ranges from just below 1.5 to 3.5, in increments of 0.5. Each point on the graph has error bars above and below representing plus and minus 1 standard error. The data on the graph are as follows: (1, 3.25 plus or minus 0.1); (2, 2.5 plus or minus 0.1); (3, 2.2

plus or minus 0.1); (4, 2.1 plus or minus 1); (5, 1.76 plus or minus 1); (6, 1.75 plus or minus 1); (7, 1.76 plus or minus 1); (8, 1.76 plus or minus 1); (9, 1.65 plus or minus 1); and (10, 1.75 plus or minus 1). All data are approximate.

Return to A graph plots average number of attempts to eat shrimp against time to illustrate the response of stickleback fish to the sight of brine shrimp in a glass tube that prevented the fish from eating the shrimp

Extended description for: Figure 52.2 Metabolic rates of mammals and body size

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Part a is titled Relationship between

body mass and total metabolic rate. The horizontal axis is labeled body mass (kilogram) (log scale) and ranges from 10 superscript negative 3 to 10 superscript 3, in increments of 10 superscript 1. The vertical axis is labeled B M R (L O subscript 2 per hour) (log scale) and ranges from 10 superscript negative 2 to 10 superscript 3, in increments of 10 superscript 1. A diagonal line on the graph begins just over halfway between 10 superscript negative 3 on the horizontal axis and just above 10 superscript negative 2 on the vertical axis and ends at halfway between 10 superscript 3 and 10 superscript 4 on the horizontal axis and just below halfway between 10 superscript 2 and

10 superscript 3 on the vertical axis. The data on the graph are as follows. Shrew: Just over halfway between 10 superscript negative 3 and 10 superscript negative 2 on the horizontal axis and just over halfway between 10 superscript negative 2 and 10 superscript negative 1 on the vertical axis, located above the diagonal line; Harvest mouse: Just before 10 superscript negative 2 on the horizontal axis and just below halfway between 10 superscript negative 2 and 10 superscript negative 1 on the vertical axis, located just below the diagonal line; Mouse: Just under halfway between 10 superscript negative 2 and 10 superscript negative 1 on the

horizontal axis and just over halfway between 10 superscript negative 2 and 10 superscript negative 1 on the vertical axis, located slightly below the diagonal line; Ground squirrel: Very slightly below 10 superscript negative 1 on the horizontal axis and very slightly below 10 superscript negative 1 on the vertical axis, located slightly below the diagonal line; Rat: located halfway between 10 superscript negative 1 and 1 on the horizontal axis and halfway between 10 superscript negative 1 and 1 on the vertical axis, located slightly below the diagonal line; Cat: located just under halfway between 1 and 10 on the horizontal axis and just above 1 on the vertical axis, located very

slightly above the diagonal line; Dog: located just past 10 on the horizontal axis and approximately halfway between 1 and 10 on the vertical axis, located slightly below the diagonal line; Sheep: located just over halfway between 10 and 10 superscript 2 on the horizontal axis at 10 on the vertical axis and on the diagonal line; Human: located just before 10 superscript 2 on the horizontal axis and just above 10 on the vertical axis, located very slightly above the diagonal line; Horse: located three-quarters of the way from 10 superscript 2 to 10 superscript 3 on the horizontal axis and just below 10 superscript 2 on the vertical axis, located just above the diagonal line;

and Elephant: located halfway between 10 superscript 3 and 10 superscript 4 on the horizontal axis and just under halfway between 10 superscript 2 and 10 superscript 3 on the vertical axis, located very slightly above the diagonal line.

Part b is titled Relationship between body mass and per-kilogram metabolic rate. The horizontal axis is labeled body mass (kilograms) (log scale) and ranges from 10 superscript negative 3 to 10 superscript 3. The vertical axis is labeled B M R (L O subscript 2 per hour) (per kilograms) and ranges from 0 to 8, in increments of 1. A curve begins at three-quarters of the way between 10 superscript

negative 3 and 10 superscript negative 2 on the horizontal axis and 7.4 on the vertical axis and runs down almost vertically, angling slightly to the right, until it begins to curve at just before 10 superscript negative 2 on the horizontal axis and 2.8 on the vertical axis before leveling off to end running almost horizontally along the horizontal axis at the right end of the horizontal axis and 0 on the vertical axis. All of the points are located on the curve except for cat, which is very slightly above it. The data on the graph are as follows: Shrew: Three-quarters of the way from 10 superscript negative 3 to 10 superscript negative 2 on the horizontal axis and 7.3 on the vertical

axis; Harvest mouse: 10 superscript negative 2 on the horizontal axis and 2.6 on the vertical axis; Mouse: just before halfway between 10 superscript negative 2 and 10 superscript negative 1 on the horizontal axis and 1.6 on the vertical axis; Ground squirrel: 10 superscript negative 1 on the horizontal axis and 1 on the vertical axis; Rat: Halfway between 10 superscript negative 1 and 1 on the horizontal axis and 9 on the vertical axis; Cat: Halfway between 1 and 10 on the horizontal axis and 7 on the vertical axis; Dog: Just past 10 on the horizontal axis and 3 on the vertical axis; Sheep: Three-quarters of the way from 10 to 10 superscript 2 on the horizontal axis and 2 on the

vertical axis; Human: Just before 10 superscript 2 on the horizontal axis and 1.5 on the vertical axis; Horse: Just before 10 superscript 3 on the horizontal axis and 0.5 on the vertical axis; and Elephant: Three-quarters of the way between 10 superscript 3 and 10 superscript 4 on the horizontal axis and 0.25 on the vertical axis. All data are approximate.

Return to Figure 52.2 Metabolic rates of mammals and body size

Extended description for: Figure 52.5 Trophic levels

Organisms are depicted on the left, and a column on the right specifies the trophic levels. A horizontal layer of grass across the bottom of the illustration is labeled primary

producer: 1000 kilograms of grasses. This is labeled as trophic level 1. A small horizontal rectangle approximately one-fourth the length of the layer of grass but slightly taller shows several mice and is labeled Herbivore (primary consumer): 100 kilograms of mice. This is labeled as trophic level 2. Above this rectangle, a smaller vertical rectangle with a width that is about one-third the length of the larger rectangle shows a snake and is labeled predator (secondary consumer): 10 kilograms of snakes. This is labeled as trophic level 3. Above this rectangle, a very thin vertical rectangle shows a hawk and is labeled predator (tertiary consumer): 1 kilograms of hawks.

This is labeled as trophic level 4. Text below the entire illustration reads, “From the base of plant productivity, about 10 percent of the biomass of each trophic level is passed on to the next-higher level.”

Return to Figure 52.5 Trophic levels

Extended description for: Figure 52.6 A simplified food web

The diagram shows primary producers in the first trophic level on the bottom, primary consumers in the secondary trophic level above, secondary consumers in the third trophic level above, and tertiary

consumers in the fourth trophic level at the top. An arrow labeled wastes and dead organisms extends down from tertiary consumers to a box labeled decomposers, detritivores, scavengers from which arrows point back to the primary producers. The primary producer layer at the first trophic level has aquatic plants on the left and green grass on the right. Six arrows point up from the first trophic level to organisms in the second trophic level. From left to right, the organisms in the second trophic level indicated by arrows from aquatic plants are as follows: a shrimp, a fish, and a bird at the boundary between the aquatic and land-based plants. From left to right, the organisms in

the second trophic level indicated by arrows from grass are a duck, a mouse, and a grasshopper. Arrows point from the shrimp to a raccoon in the third trophic level and to the arrow labeled wastes and dead organisms. Arrows point from the shrimp and fish to the raccoon. Arrows point from the bird to a snake in the secondary consumer level, to an owl in the tertiary consumer level, and to the arrow labeled waste and dead organisms. An arrow points from the duck to the owl. Arrows point from the mouse to the snake and the owl. Arrows point from the grasshopper to the duck, snake, and owl and to a fox at the third trophic level. Arrows point from the

grasshopper to the duck, to a mole at the third trophic level and to a fox at the third trophic level. An arrow points from the fox to a hawk at the fourth trophic level. Arrows point from the mole to the fox and the hawk. Arrows point from the snake to the hawk and the owl. Arrows point from the boxes labeled secondary consumers and primary consumers to the arrow labeled wastes and dead organisms that ends at decomposers, detritivores, and scavengers. A small illustration shows an earthworm in soil next to an irregularly shaped structure with many strands extending in all directions and below a circle showing a rod-shaped bacterium with many small hair-like

structures over its body and with flagella extending from its left end. An arrow points from the earthworm and bacterium to the box labeled primary consumers.

Return to Figure 52.6 A simplified food web

Extended description for: Figure 52.7 The carbon cycle

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The left front of the illustration shows ocean except for a small piece of land to the lower left. A space-filling model showing a gray sphere with red spheres on each side is labeled

dissolved C O 2. A green arrow points from dissolved C O 2 to text reading producers in a clockwise circle of arrows below. Arrows point from producers to decomposers, from decomposers to consumers, and from consumers back to producers. Yellow arrows point from decomposers, consumers, and producers back to dissolved C O 2. Another yellow arrow splits from the arrow from decomposers to C O 2 to bend into the soil to point to a space-filling model of C O 2 labeled buried C O 2. A green arrow points from buried C O 2 to a dark region in the soil and is accompanied by text reading, “Burial, Buried carbon transforms into fossil fuels.” A green arrow points to the soil

across the bottom of the cutaway showing the contents of the ocean, and text accompanying this arrow reads, “Sedimentation, Calcium carbonate precipitates out of the water as sediments.” From the black region in the soil, a small black horizontal line extends right to a vertical horizontal line that leads up to an oil well. A yellow arrow points from the oil well to a molecule of atmospheric C O 2 above and is accompanied by text reading, “Extraction, Human extraction of fossil fuels brings carbon to Earth's surface, where it can be combusted.” To the left of the oil well is a snow-capped mountain with smoke above it with a fire to its left. A yellow arrow

points up from the fire to atmospheric C O 2 accompanied by text reading, “Combustion, Fossil fuels and plant matter are converted to C O 2.” There is a grassy, hilly region, and then a road extends horizontally across the piece of land. A truck is on the land. A farmhouse is in front of the highway on the right side of the figure with farmlands in front of it. In the region to the left of the farmland, a cycle of clockwise arrows is depicted. In this cycle, arrows point from decomposers, to consumers, to producers, and back to decomposers. Yellow arrows point from decomposers, consumers, and producers to atmospheric C O 2 accompanied by text reading,

“Respiration, Sugars are converted back into C O 2.” The yellow arrow from decomposers splits so that half extends up to atmospheric C O 2 and the other half extends down to buried C O 2 that can be transformed into fossil fuels. A green arrow points from atmospheric C O 2 to producers in the cycle accompanied by text reading, “Photosynthesis, C O 2 is converted into sugar.” A green arrow points from atmospheric C O 2 to dissolved C O 2 in the ocean and a yellow arrow points in the reverse direction with both arrows accompanied by text reading, “Exchange, C O 2 in the atmosphere and C O 2 dissolved in water are constantly exchanged.”

Return to Figure 52.7 The carbon cycle

Extended description for: A figure shows interactions between a primary producer, two primary consumers, a secondary consumer, and a tertiary consumer

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A horizontal layer of grass is labeled primary producer. Two arrows point up from the grass to two primary

consumers, a mouse and a grasshopper. Arrows point up from the mouse and the grasshopper to a secondary consumer, a fox. An arrow points up from the fox to a tertiary consumer, an eagle.

Return to A figure shows interactions between a primary producer, two primary consumers, a secondary consumer, and a tertiary consumer

Extended description for: A visual synthesis figure is titled thermoregulation in an endotherm and illustrates how a rock squirrel responds to changing temperatures. A visual synthesis figure is titled thermoregulation in an ectotherm and illustrates how a zebra-tailed lizard responds to changing temperatures. A diagram shows the movement of carbon

dioxide in the terrestrial carbon cycle. A figure shows the marine carbon cycle

Text at the top of the figure reads, “Thermoregulation in an endotherm. Endotherms regulate their body temperature primarily by physiological means, such as increasing or decreasing their metabolic activity, which generates heat as a by-product.”

A graph is presented as a horizontal

bar that shows time on the horizontal axis and temperature on the vertical axis. The horizontal axis is labeled with three times: 4 a m on the left, 8 a m in the center, and 12 p m on the right. A dashed line at one-quarter of the height of the vertical axis is labeled burrow temperature and is constant across the graph. A solid line at three-quarters of the height of the vertical axis is labeled core body temperature and is constant across the graph. A curve labeled outside temperature begins just above the horizontal axis and gradually begins to rise at just past 6 a m, then rises relatively constantly to peak at 12 p m and then descends symmetrically until it ends at just above half the

height of the vertical axis at the right end of the graph.

An illustration below shows a desert environment with mountains in the background and the sun setting behind the mountains. On the left, below the 4 a m time on the graph, a rock squirrel is depicted curled up in a shallow, round burrow with a narrow passage to an opening to the surface. A box below shows what happens within the squirrel's body. A box labeled cold nighttime temperature has an arrow pointing downward through a plus symbol to a box labeled hypothalamus. Two arrows labeled with plus symbols point down from the box labeled

hypothalamus. The left-hand arrow points to a box labeled, Physiological: shivering, peripheral vasoconstriction, increase in metabolic rate. The right-hand arrow points to a box labeled motor cortex from with an arrow with a plus symbol on it points down to a box labeled, Behavioral: burrowing, huddling. An arrow pointing down from between the boxes labeled physiological and behavioral points to a box labeled, Increased heat production, decreased heat loss. From this box, a line with a minus symbol extends up to a short perpendicular line next to the box labeled hypothalamus. Text below reads, “At night when it is cold, the

rock squirrel enters its burrow, and physiological mechanisms generate heat to maintain a constant core body temperature." The squirrel is depicted above ground at 8 a m with its head and tail erect. A patch of fur on its neck is cut away to show muscle, the side of its head is cut away to show the position of the hypothalamus at the lower part of the brain, and a paired blood vessel is depicted in its neck. A box labeled cool nighttime temperature has an arrow pointing downward through a plus symbol to a box labeled hypothalamus. Two arrows labeled with plus symbols point down from the box labeled hypothalamus. The left-hand arrow points to a box labeled, Physiological:

peripheral vasoconstriction. The right-hand arrow points to a box labeled motor cortex, from which an arrow with a plus symbol on it points down to a box labeled, Behavioral: increasing activity. An arrow pointing down from between the boxes labeled physiological and behavioral points to a box labeled, Increased heat production, decreased heat loss. From this box, a line with a minus symbol extends up to a short perpendicular line next to the box labeled hypothalamus. Text below reads, “The squirrel is most active in the early morning and late afternoon, when it is cool.” The squirrel is depicted resting beneath a plant with pointed leaves at 12 p m. A box

labeled hot daytime temperature has an arrow pointing downward through a plus symbol to a box labeled hypothalamus. Two arrows labeled with plus symbols point down from the box labeled hypothalamus. The left-hand arrow points to a box labeled, Physiological: panting, peripheral vasodilation, decrease in metabolic rate. The right-hand arrow points to a box labeled motor cortex, and an arrow with a plus symbol on it points down to a box labeled, Behavioral: seeking shade, licking forelimbs. An arrow pointing down from between the boxes labeled physiological and behavioral points to a box labeled, Decreased heat production, increased heat loss. From

this box, a line with a minus symbol extends up to a short perpendicular line next to the box labeled hypothalamus. Text below reads, “To avoid overheating during the day, the squirrel must decrease its exposure to the sun, and physiological mechanisms cool the body.”

Text at the top of the figure reads, “Thermoregulation in an ectotherm. Ectotherms gain or lose heat to their environment, and so their primary means of regulating their body temperature is behavioral, increasing or decreasing their exposure to sun and hot surfaces.”

A graph is presented as a horizontal

bar that shows time on the horizontal axis and temperature on the vertical axis. The horizontal axis is labeled with three times: 4 a m on the left, 8 a m in the center, and 12 p m on the right. A dashed line at one-quarter of the height of the vertical axis is labeled burrow temperature and is constant across the graph. A solid line labeled core body temperature runs along the dashed line until 5 a m, then rises to just above half the height of the graph and moves up and down throughout a narrow range across the rest of the graph. A curve labeled outside temperature begins just above the horizontal axis and gradually begins to rise at just past 6 a m, then rises relatively constantly to peak at

12 p m and then descends symmetrically until it ends at just above half the height of the vertical axis at the right end of the graph.

An illustration below shows a desert environment with mountains in the background and the sun setting behind the mountains. On the left, below the 4 a m time on the graph, a zebra-tailed lizard is depicted in a narrow burrow that has a narrow opening to the surface to the left and extends beneath rocks to the right. A box below shows what happens within the lizard's body. A box labeled cold nighttime temperature has an arrow pointing downward through a plus symbol to a box labeled

hypothalamus. An arrow labeled with a plus symbol points down to a box labeled hypothalamus. From the box labeled hypothalamus, an arrow with a plus symbol points down to a box labeled motor cortex, from which an arrow with a plus symbol points down to a box labeled, Behavioral: burrowing. An arrow points down to a box labeled, Decreased heat loss. From this box, a line with a minus symbol extends up to a short perpendicular line next to the box labeled hypothalamus. Text below reads, “At night, lizards retreat to burrows in order to maintain a constant, intermediate temperature.” The lizard is depicted looking alert and resting on a rock at 8 a m. A patch

of skin on its neck is cut away to show muscle, the side of its head is cut away to show the position of the hypothalamus at the lower part of the brain, and a paired blood vessel is depicted in its neck. A box labeled cool nighttime temperature has an arrow pointing downward through a plus symbol to a box labeled hypothalamus. Two arrows labeled with plus symbols point down from the box labeled hypothalamus. The left-hand arrow points to a box labeled, Physiological: peripheral vasodilation (heat gain from sun or rock). The right-hand arrow points to a box labeled motor cortex from which an arrow with a plus symbol on it points down to a box labeled,

Behavioral: increasing exposure to sun, lying on hot surfaces, increasing activity. An arrow pointing down from the behavioral box points to a box labeled, Increased heat gain. From this box, a line with a minus symbol extends up to a short perpendicular line next to the box labeled hypothalamus. Text below reads, “In the morning, the lizard basks in the heat of the sun. In the evening, it warms itself by heat radiated from rocks heated by the day time sun.” The lizard is depicted resting beneath a rock at 12 p m. A box labeled hot daytime temperature has an arrow pointing downward through a plus symbol to a box labeled hypothalamus. An arrow

labeled with a plus symbol points down from the box labeled hypothalamus to a box labeled motor cortex from which an arrow with a plus symbol on it points down to a box labeled, Behavioral: seeking shade, lying on cool ground, decreasing activity. An arrow pointing down from the box labeled behavioral points to a box labeled, Increased heat loss. From this box, a line with a minus symbol extends up to a short perpendicular line next to the box labeled hypothalamus. Text below reads, “During the hottest part of the day, the lizard regulates its temperature by seeking shade.”

Text in a box at the top of the figure

reads, “Terrestrial carbon cycle, Carbon (C) enters the cycle through photosynthesis and is transferred through food webs by consumers. Decomposers complete the return of carbon to the atmosphere as C O 2.” Text in a box at the bottom reads, “Trophic pyramids: As each trophic group obtains carbon, a portion gets transferred to the next higher trophic group through consumption. For this reason, only a portion of the energy taken in is available to consumers further up the food web.”

A circle showing the cycle is depicted with a mountain in the background, vegetation in the center and left background, water in the right-hand

background, and sandy soil in the lower-right background. Within the highlighted circle showing the cycle, there is a tree at the top. Accompanying text reads, “Primary producers: Autotrophs that fix C O 2 into organic matter. Photosynthesis: 6 C O 2 plus 6 H 2 O yields C 6 H 12 O 6 plus 6 H 2 O.” A gray sphere with red spheres on each side is to the upper right outside of the circle, and a purple arrow labeled photosynthesis points from it to the tree. Two arrows, one purple and one orange, point from the tree to a yellow-and-black striped moth larva with a red head that is depicted on a leaf. An arrow points right to show that the moth larva becomes an adult moth,

depicted as a brown moth with thin wings. Accompanying text reads, “Primary consumers: Heterotrophs that feed on primary producers. Aerobic respiration: C 6 H 12 O 6 plus 6 O 2 yields 6 C O 2.” A purple arrow points from the moth to the C O 2 molecule in the atmosphere outside of the circle. Two additional moths are depicted in the background. Two arrows, one purple and one orange, point from the moth to a solenodon, depicted as a mammal with mostly brown fur, a white patch of fur behind its neck, and a long narrow snout. A purple arrow labeled aerobic respiration points from the solenodon to the carbon dioxide molecule in the atmosphere. Accompanying text

reads, “Secondary consumers: Heterotrophs that feed on other consumers.” Two arrows, one purple and one orange, point from the solenodon to a skeleton in the ground below. Text beneath the skeleton reads, decomposers. Accompanying text reads, “Decomposers: Heterotrophs that return C O 2 and nutrients to the environment. Fungi, bacteria, amoeba, protists.” Accompanying text reads, aerobic respiration, anaerobic respiration, fermentation; and a purple arrow points up to C O 2 in the atmosphere. An orange arrow points right to a yellow sphere labeled P O 4 superscript 3 minus . An orange arrow labeled weathering points from

this phosphate back to the tree. Another orange arrow points away from this phosphate off of the page, and a third orange arrow points back to this phosphate from off of the page.

Text in a box at the top of the figure reads, “Marine carbon cycle: In marine ecosystems, carbon enters food webs through photosynthesis and is transferred from one trophic group to another by consumption.” An area of land is depicted in the background with ocean in front. A factory emitting smoke from three smokestacks is on the right end of the piece of land. Text in an accompanying box reads, “Human

impact, Humans impact the carbon cycle primarily by extracting and burning fossil fuels, which puts more C O 2 in the air, and by removing forests that serve as a major reservoir for carbon." A gray sphere with red spheres on each side is labeled C O 2 and is in the atmosphere. Purple arrows point up and down from this C O 2 to a similar C O 2 in a sphere in the ocean. This sphere is overlapped by a sphere to the upper left that contains a text box reading, "The microbial loop, Bacteria play a major role in the marine carbon cycle, feeding on the contents of lysed cells and, in turn, serving as food for other consumers." Within the sphere are many differently shaped protists. Text

reads, “Viruses lyse cells, releasing organic molecules.” From this box, two arrows, one purple and one orange, point to a box reading, “Bacteria feed on organic molecules, providing food for other consumers.” Six rod-shaped bacteria are depicted below. Two sets of purple and orange arrows extend away from the bacteria into the main circle. The first pair of arrows points to a protist that has a tubular body that widens to the base of a triangular end with small hair-like cilia all around except for the flat end of the triangular part, which has longer hair-like structures. The second pair of arrows points to a copepod, depicted as an organism with a half-oval with two curved

protrusions at its head and a segmented body that ends with two hair-like protrusions. Several cells labeled phytoplankton in the smaller microbial loop circle have a pair of arrows, one purple and one orange, that also point to the same protist, and a similar pair of arrows points from the protist to the copepod. A pair of arrows, one purple and one orange, point from the copepod to a fish that is disc-shaped and yellow. A purple arrow points from the fish to C O 2 in the water. A pair of arrows, one purple and one orange, point from the fish to a fish skeleton on the ground accompanied by text reading, aerobic respiration, anaerobic respiration, fermentation. A purple

arrow labeled aerobic respiration points from the skeleton to the C O 2 in the water. A purple arrow from the C O 2 in the water points to a purple arrow labeled photosynthesis that points to the phytoplankton. A series of two orange arrows points from the fish skeleton to an arrow to a yellow sphere labeled P O 4 superscript 3. An arrow labeled sedimentation points back through the two arrows from the fish skeleton to the phosphate and continue past a label reading tectonic uplift until they leave the frame. An orange arrow labeled runoff enters the frame and points back to the phosphate. An arrow labeled upwelling points from the phosphate to the phytoplankton.

Extended description for: Figure 53.2 Geographic range

At the upper left, a small bird is depicted above four maps of the continental United States. The maps are labeled from left to right as 1918, 1926, 1949, and 2003. The maps have colored regions and colored spots to show the distribution of the starling. In 1918, the starling was found in a continuous area in southern Vermont

and New Hampshire, Massachusetts, Connecticut, Rhode Island, eastern New York, eastern Pennsylvania, Delaware, Maryland, and eastern Virginia. Dots show that it was also found in western New York, two locations in Ohio, West Virginia, western North Carolina, a location at the eastern border of North and South Carolina, a location at the borders of south central Tennessee, Alabama, and Georgia, a location in south central Alabama, a location in southeastern Georgia, and a location in northern Florida. In 1926, the starling was found continuously across the northeastern United States as far west as eastern Michigan, eastern Indiana, eastern Kentucky,

eastern Tennessee, and eastern Georgia. It was also found in new isolated locations in Wisconsin, Indiana, Louisiana, and Texas. In 1949, the starling was found continuously as far west as a roughly diagonal line from north central Montana to the border of Alabama and Louisiana. It was also found in new isolated locations in Idaho, Washington, Oregon, California, and Arizona. In 2003, the starling was found continuously across the entire country. All data are approximate.

A figure shows a photo of antelopes overlaid with the words, Population size. To the right, a green arrow with a plus symbol pointing to the photo is labeled birth, and a red arrow with a minus symbol pointing away from the

photo is labeled death. Below, a green arrow with a plus symbol pointing up to the photo is labeled immigration, and a red arrow with a minus symbol pointing away from the photo is labeled emigration.

Return to Figure 53.4 Changes in population size

Extended description for: A graph shows changes in the population of Japan from 1900 to 2005

The horizontal axis is labeled year and ranges from just below 1900 to 2005, in increments of 20. The vertical axis is labeled birth and death rates in

Japan (millions) and ranges from 0 to 3.0, in increments of 0.5. Two curves are depicted on the graph, one representing births and one representing deaths. The curve for births begins at (1898, 1.4) and increases to (1900, 1.5), remains horizontal briefly, then decreases jaggedly to (1906, 1.4), then increases jaggedly to (1938, 2.2), then drops to (1939, 1.9), then increases with a single dip to peak at (1948, 2.7), then decreases to (1957, 1.6), then rises to (1963, 1.8), then decreases to (1964, 1.4), then increases with a single dip to (1972, 2.1), and then gradually and slightly jaggedly decreases to (2005, 0.9). The curve for deaths begins at (1899, 0.9) and increases jaggedly to

peak at (1918, 1.5), then jaggedly decreases to (1924, 1.2), then follows a jagged horizontal path to (1939, 0.25), then decreases to (1952, 0.7), then follows a jagged, roughly horizontal path to (1982, 0.75), and then follows a jagged, increasing path to end at (2005, 1.35). All data are approximate.

Return to A graph shows changes in the population of Japan from 1900 to 2005

Extended description for: Figure 53.5 Exponential growth model

The horizontal axis is labeled time, and the vertical axis is labeled population size. A curve begins at the left end of the horizontal axis just

above the bottom of the vertical axis and begins almost horizontally, then gradually begins to increase more and more rapidly until it is almost vertical by three-quarters of the way across the graph. Text on the graph reads, (lowercase d uppercase N) divided by (lowercase d lowercase t) equals r subscript max end subscript N.

Return to Figure 53.5 Exponential growth model

Extended description for: A graph shows the growth of rabbit populations with italicized r end italics subscript max equals 0.5 and 1.5

The horizontal axis of the graph is labeled time (months) and ranges from 0 to 6, in increments of 1. The

vertical axis is labeled population size and ranges from 0 to 200, in increments of 20. The curve for italicized r end italics subscript max equals 1.5 begins at (1, 0) and rise immediately at a slight diagonal, then curves upward more rapidly beginning at (4.2, 38) before forming a steep diagonal line that ends at (6, 161). The curve for italicized r end italics subscript max equals 0.5 begins at (1, 0) and rises slowly until (5.3, 10), at which point it rises slightly more rapidly to end at (6, 18). All data are approximate.

Return to A graph shows the growth of rabbit populations with italicized r end italics subscript max equals 0.5

and 1.5

Extended description for: Figure 53.6 Survivorship curves

The horizontal axis of the graph plots age while vertical axis plots percentage of surviving organisms on a log scale ranging from 1 to 100, in

exponential increments of 10. Three curves are plotted starting from 100 on the vertical axis and ending at the same point on the horizontal axis. The Type 1 curve descends at a gradual diagonal until it reaches three-quarters of the length of the horizontal axis and just over three-quarters of the height of the vertical axis, at which point it curves down and then descends almost vertically to end at the lower right corner of the graph. Accompanying text reads, "Type 1: most humans and other large mammals survive their early years and show a steep decline in the last part of their life-span." The Type 2 curve forms a diagonal line that begins at 100 on the vertical axis and

ends at the lower right corner of the graph. Accompanying text reads, “Type 2: small mammals and birds tend to lose numbers steadily throughout their lives.” The Type 3 curve begins at 100 on the vertical axis and descends rapidly until it begins to curve more gradually at one-quarter of the length of the horizontal axis and one-quarter of the height of the vertical axis, at which point it declines more slowly to end at the lower right cover of the graph. Accompanying text reads, “Type 3: Many fish, frogs, and herbaceous plants do not survive the earliest period of life, but those that do survive show only slow additional declines over time.” All data are

approximate.

Return to Figure 53.6 Survivorship curves

Extended description for: Figure 54.3 Density-independent factors in population growth

An illustration of an apple thrip appears at the upper right of the graph as a thin insect with long, clear wings; a pale thorax and head; and two antennae. The horizontal axis is

labeled year and ranges from 1932 to 1946, except that the year 1944 is missing. The vertical axis is labeled mean number of thrips per flower and ranges from 0 to 700, in increments of 100. Bars extend up from each date on the horizontal axis, and a dashed line labeled predicted population roughly traces the path across the top of the bars. The data in bars are presented with the year followed by the height of the bar, representing the mean number of thrips. 1932: 120; 1933: 40; 1934: 50; 1935: 110; 1936: 40; 1937: 110; 1938: 330; 1939: 530; 1940: 130; 1941: 270: 1942: 390; 1943: 60; 1945: 90; and 1946: 200. The dashed line labeled predicted population begins at (1932,

90) and runs down to (1934, 50), then runs up to (1935, 150), then down to (1936, 90), then up to (1937, 110), the up to (1989, 605), then down to (1940, 110); then up to (1941, 280), then up to (1942, 305), then down to (1943, 55), then up slightly to (1945, 56), then up to (1946, 170). All data are approximate.

Return to Figure 54.3 Density-independent factors in population growth

Extended description for: Figure 54.4 Density-dependent growth in two species of Paramecium

Graph a is labeled, Low-food supply. The horizontal axis of the graph is labeled days and runs from 0 to 18, in increments of 2. The vertical axis is labeled number of individuals and runs from 0 to 250, in increments of 50. An illustration of italicized Paramecium aurelia end italics in the

upper left quarter of the graph shows an elongated oval organism that is narrower at the upper right than at the lower left, has organelles inside, and has hair-like cilia all around the outside of its cell membrane. The data in the graph are as follows. The curve labeled italicized K end italics equals 105 and italicized P. aurelia end italics begins at (0, 0) and rises rapidly before beginning to curve at (5.6, 80) and then leveling off at (7.5, 102) to run horizontally until it ends just before day 16. The curve labeled italicized K end italics equals 64 and italicized P. caudatum end italics begins at (0, 0) and rises more slowly than the first curve before beginning to curve at (6.4, 60) and then leveling

off at (8, 60) to run horizontally until it ends just before day 16.

Graph b is labeled, High-food supply. The horizontal axis of the graph is labeled days and runs from 0 to 18, in increments of 2. The vertical axis is labeled number of individuals and runs from 0 to 250, in increments of 50. An illustration of italicized Paramecium caudatum end italics near the bottom just to the right of the center of the graph is a long oval with organelles inside and hair-like cilia all around the outside of its cell membrane. It is larger than italicized P. end italics aurelia end italics. The data in the graph are as follows. The curve labeled italicized K end italics

equals 195 and italicized P. aurelia end italics begins at (0, 0) and, after a slower start, rises rapidly beginning at (1.4, 35) before beginning to curve at (8, 180) and then leveling off at (9, 190) to run horizontally until it ends at day 17. The curve labeled italicized K end italics equals 137 and italicized P. caudatum end italics begins at (0, 0) and initially rises more rapidly than the first curve before beginning to curve at (5.9, 130) and then leveling off at (8, 145) to run horizontally until it ends just after day 16. All data are approximate.

Return to Figure 54.4 Density-dependent growth in two species of Paramecium

Extended description for: Figure 54.5 Logistic growth model

The horizontal axis is labeled time, and the vertical axis is labeled population size. The curve begins at the origin and moves slightly upward

to one-quarter of the length of the horizontal axis near the bottom of the vertical axis, at which point it begins to rise more rapidly and runs almost diagonally from just before the midpoint of the horizontal axis at one-eighth the height of the vertical axis to just after the midpoint of the horizontal axis at three-quarters the height of the vertical axis. At this point, it bends and ends by running almost horizontally for a short distance. The overall curve resembles an elongated S shape with a very long central line. Text accompanying the bottom of the graph where the curve begins to increase more rapidly reads, “Growth rate is exponential.” Text accompanying the almost diagonal

part of the graph just before it begins to curve reads, “Growth rate begins to slow.” A dashed line from the horizontal part at the top of the curve to the vertical axis is labeled carrying capacity (italicized K end italics). Text just above the horizontal part at the end of the curve reads, “Growth rate eventually falls to zero.” All data is approximate.

Return to Figure 54.5 Logistic growth model

Extended description for: Figure 54.6 Overshoot and die-off in reindeer

The horizontal axis of the graph is labeled year and ranges from 1910 to 1950, in increments of 10. The vertical axis is labeled population size and ranges from 0 to 2400, in increments of 4000. An illustration just to the left of the center of the graph shows a

large hoofed reindeer with a short tail, a rounded protrusion beneath its neck, and large antlers. The data in the graph are as follows. A solid curve begins at (1910, 25) and rises with a slight jag just before a peak at (1922, 320), then drops to (1923, 200), then rises with some slight jags to peak at (1930, 2050) before descending slightly to (1938, 1900) and then descending with some slight jags to (1950, 0). A dashed line labeled growth trend shows the general trend of population growth. It begins at (1910, 25) with the blue line and curves smoothly upward with a concave-up center to then run almost vertically to (1930, 2050). All data are approximate.

Return to Figure 54.6 Overshoot and die-off in reindeer

Extended description for: Figure 54.7 Human population growth in the United States

The horizontal axis is labeled year and ranges from 1790 to 2030, in major increments of 40 and minor increments of 20. The vertical axis is labeled U.S. population (millions) and

ranges from 0 to 350, in increments of 50. The data in the graph are as follows. A curve begins at 1790 just above the vertical axis. This curve rises slowly and gradually begins to curve upward as it increases from (1830, 10) to (1870, 45). It then rises almost diagonally to (1915, 105) before bending to the right to (1930, 140) and then rising almost diagonally to end at (2015, 335). There are dots plotted along the entire line, placed close together from 0 to 1950 and then slightly more spaced out to 2015. A dashed line labeled predicted logistic growth begins at (1930, 125) and rises slightly above the solid curve before crossing the solid curve at (1950, 155) and then curving right to end just

before 2010 at 199. All data is approximate.

Return to Figure 54.7 Human population growth in the United States

Extended description for: A graph plots population size against time for an animal species and indicates the carrying capacity

The horizontal axis is labeled time, and the vertical axis is labeled population size. A curve begins at the left end of the horizontal axis just above the bottom of the horizontal

axis and runs diagonally for one-quarter of the length of the horizontal axis, then curves upward and rapidly becomes almost vertical until it reaches a point just above the midpoints of the horizontal and vertical axes. From this point to the right, the line oscillates up and down with increasingly smaller peaks and inverse peaks until it ends following a shallow peak at the right end of the horizontal axis near the midpoint of the vertical axis. To the left of this series of oscillating peaks, text reads carrying capacity. All data are approximate.

Return to A graph plots population size against time for an animal

species and indicates the carrying capacity

Extended description for: A graph plots population size against days to show the increase in population size of italicized Euglena gracilis end italics over time

The horizontal axis of the graph is labeled days and ranges from 0 to 11,

in increments of 1. The vertical axis is labeled population size (number of cells times 10 cubed) and ranges from 0 to 300, in increments of 50. Data points are depicted on the graph and joined by a line that forms a curve that initially rises diagonally and then levels off to run horizontally. The points on the graph are as follows: (1, 100), (2, 155), (3, 225), (4, 250), (5, 250), (6, 250), (7, 250), (8, 250), (9, 250), and (10, 250). All data are approximate.

Return to A graph plots population size against days to show the increase in population size of italicized Euglena gracilis end italics over time

Extended description for: A graph plots population size against days to show the increase in population size of italicized Euglena gracilis end italics over time

The horizontal axis of the graph is labeled days and ranges from 0 to 11, in increments of 1. The vertical axis is

labeled population size (number of cells times 10 cubed) and ranges from 0 to 250, in increments of 50. Data points are depicted on the graph and joined by a curve that initially rises with a concave-down shape and then levels off to run horizontally. The points on the graph are as follows: (1, 100), (2, 150), (3, 180), (4, 200), (5, 210), (6, 210), (7, 210), (8, 210), (9, 210), and (10, 210). All data are approximate.

Return to A graph plots population size against days to show the increase in population size of italicized Euglena gracilis end italics over time

Extended description for: A graph plots population size against time to produce an exponential curve accompanied by descriptive text

The horizontal axis is labeled time. The vertical axis is labeled population size. A curve begins near the beginning of the horizontal axis at the

bottom of the vertical axis and runs horizontally to just past the midpoint of the horizontal axis, at which point it begins to rise. Text above the horizontal part of the curve reads, “Initial growth is slow.” The curve forms a concave-up shape and curves even more sharply to rise almost vertically to end at seven-eighths the length of the horizontal axis and the top of the vertical axis. Text accompanying the beginning of the curve reads, “Growth begins to rapidly increase as more individuals make more offspring.” Text at the upper end of the curve reads, “Exponential growth will continue indefinitely.”

Return to A graph plots population size against time to produce an exponential curve accompanied by descriptive text

Extended description for: A graph plots population size against time to show a logistic curve that is labeled to indicate what is happening at different parts of the curve

The horizontal axis is labeled time, and the vertical axis is labeled

population size. The curve begins at the origin and rises slowly, then begins to rise rapidly just before the midpoint of the horizontal axis. Accompanying text reads, “The growth rate is increasing.” The curve begins to rise even more rapidly across the center of the graph, and then begins to level off at two-thirds of the length of the horizontal axis and three-quarters of the height of the vertical axis. The graph then curves and levels off to run horizontally to end at the right end of the graph. A dashed line along this horizontal part of the graph runs left to the vertical axis and is labeled carrying capacity. Text accompanying the center of the graph, at the

midpoint of the region where it is rising most rapidly, reads, “The maximum growth rate is reached when the population reaches one half of its carrying capacity.” Text accompanying the part of the curve immediately after this region of rapid growth, where it starts to level off, reads, “The growth rate begins to decrease due to competition for resources.” Text accompanying the horizontal part of the curve at it right end reads, “The growth rate levels out as births and deaths offset each other.”

Return to A graph plots population size against time to show a logistic curve that is labeled to indicate what

is happening at different parts of the curve

Extended description for: A graph plots population size against days to illustrate the initial growth rate in a logistic growth curve

The horizontal axis is labeled days and ranges from 0 to 10 in increments of 1. The vertical axis is labeled

population size (italicized N end italics) and ranges from 0 to 250 in increments of 50. The curve begins at the origin and rises slowly, then begins to rise rapidly at (3.5, 20) and then begins to rise very rapidly from (5, 50) to (7, 150). The curve then begins to level off and runs horizontally from (8, 200) until it ends at (10, 200). A dashed line extends left from this horizontal part of the curve of 200 on the vertical axis and is labeled carrying capacity. A line pointing to (4, 25) is accompanied by text reading, “At italicized N end italics equals 25, the growth rate of the population is relatively slow at 22 individuals per day.” All data are approximate.

Return to A graph plots population size against days to illustrate the initial growth rate in a logistic growth curve

Extended description for: A graph showing a logistic curve is accompanied by text explaining what happens during the period of rapid growth in the middle of the curve

The horizontal axis is labeled days and ranges from 0 to 10, in

increments of 1. The vertical axis is labeled population size (italicized N end italics) and ranges from 0 to 250, in increments of 50. The curve begins at the origin and rises slowly, then begins to rise rapidly at (3.5, 20) and then begins to rise very rapidly from (5, 50) to (7, 150). The curve then begins to level off and runs horizontally from (8, 200) until it ends at (10, 200). A dashed line extends left from this horizontal part of the curve of 200 on the vertical axis and is labeled carrying capacity. A line pointing to (6, 100) is accompanied by text reading, “At italicized N end italics equals 100, the population achieves its maximum growth rate of 50 individuals per day.” All data are

approximate.

Return to A graph showing a logistic curve is accompanied by text explaining what happens during the period of rapid growth in the middle of the curve

Extended description for: A graph showing a logistic curve is accompanied by text explaining what happens as growth slows at the end of the curve

The horizontal axis is labeled days and ranges from 0 to 10, in

increments of 1. The vertical axis is labeled population size (italicized N end italics) and ranges from 0 to 250, in increments of 50. The curve begins at the origin and rises slowly, then begins to rise rapidly at (3.5, 20) and rises very rapidly from (5, 50) to (7, 150). The curve then begins to level off and runs horizontally from (8, 200) until it ends at (10, 200). A dashed line extends left from this horizontal part of the curve of 200 on the vertical axis and is labeled carrying capacity. A line pointing to (8.8, 190) is accompanied by text reading, “At italicized N end italics equals 190, the growth rate has slowed to 10 individuals per day.” All data are approximate.

Return to A graph showing a logistic curve is accompanied by text explaining what happens as growth slows at the end of the curve

Extended description for: Figure 55.1 Comparing species richness and evenness

Each tree community is depicted on a square of grass. A key beneath each square shows the four different types of trees and their percentages in the population. The first species is a dense coniferous tree, the second species has a rounded top, the third

species is a coniferous tree with less densely packed branches than species 1, and the fourth species has a tall trunk with a round leafy part at the top. Community 1 has four different types of trees distributed throughout the square. The key below indicates that each type of tree makes up 25 percent of the population.

Community 2 has many of the species 3 coniferous trees and relatively few other trees interspersed among them. The key below indicates that the four species of trees are represented as follows: 6 percent are species 1, 12 percent are species 2, 70 percent are species 3, and 12 percent are species 4.

Return to Figure 55.1 Comparing species richness and evenness

Extended description for: Figure 55.2 Range of tolerance

The horizontal axis is labeled temperature, and the vertical axis is labeled performance. A bell curve is depicted on the horizontal axis with its peak above the midpoint of the horizontal axis at two-thirds of the

height of the vertical axis. The left and right ends of the bell curve are labeled survive. The regions from one-quarter to just past one-third of the horizontal axis and from just under two-thirds to three-quarters of the horizontal axis are labeled survive and grow. The central part of the graph, from just part one-third of the horizontal axis to just under two-thirds of the horizontal axis, is labeled survive, grow, and reproduce. All data is approximate.

Return to Figure 55.2 Range of tolerance

Extended description for: Figure 55.3 Fundamental and realized niches

Each figure shows a relatively oval, central marshy region surrounded by a highlighted oval region of vegetation that is further surrounded by a non-highlighted outer area of vegetation. Part a is labeled red-winged blackbirds only. It shows eleven squares containing red-winged blackbirds. These birds are spread

throughout the marsh area and the highlighted oval region of vegetation. An arrow pointing into the highlighted oval reads, Fundamental niche.

Part b is labeled red-winged blackbirds and yellow-headed blackbirds. It shows four squares containing yellow-headed blackbirds in an oval enclosing the central of the marshy area. Outside of this central oval, the remaining marshy region and outer highlighted oval of vegetation contains seven squares showing red-winged blackbirds and is highlighted. An arrow pointing to this smaller region containing red-winged blackbirds reads, Realized niche.

Return to Figure 55.3 Fundamental and realized niches

Extended description for: Figure 55.4 Population cycles of lynx and hares in Canada

The horizontal axis of the graph is labeled year and ranges from below 1850 to above 1930. The left-hand vertical axis is labeled number of hares (thousands) and ranges from 0

to 160, in increments of 40. The right-hand vertical axis is labeled number of lynx (thousands) and ranges from 0 to 12, in increments of 3. At the top, an illustration shows a lynx as a cat-like animal with some spots; large, pointed ears, and a short tail next to a white hare with long ears. Two curves are depicted, one for hares and one for lynx. These curves show a pattern of hares peaking, then lynxes peaking as hares decreases, then hares decreasing again. The curve for hares begins at (1846, 25), is slightly jagged, then rises to peak at (1852, 90) before dropping to (1854, 70), then rising to (1856, 84) and then dropping to (1857, 30). The curve continues this cycle of increases and decreases with major

peaks at (1852, 158), (1875, 90), (1885, 130), (1894, 80), (1893, 65), (1911, 65), (1922, 80), and (1932, 82). The curve ends at (1934, 30). The curve for lynx begins at (1846, 2.7) and immediately rises to a peak at (1840, 4.5) before dropping to (1852, 0.75). It continues this pattern of increasing and decreasing with the following peaks: (1854, 2.8), (1865, 5.9), (1875.5, 4), (1904, 5), (1912, 3.2), (1923, 4.5), and (1934, 3.5) before ending at (1934, 3.2). All data are approximate.

Part a shows a photo of a katydid on a leaf. The katydid has wings that resemble leaves, even having a pattern that resembles the veins of the leaf on which it is standing.

Part b shows a fingertip placed near the head of a bombardier beetle. The beetle has its abdomen raised and is spraying a liquid toward the finger.

Return to Figure 55.5 Prey defenses

Extended description for: Figure 55.7 Competition between Paramecium species

Graph a is labeled italicized P. aurelia end italics grown separately. An

illustration of italicized Paramecium aurelia end italics in the upper left quarter of the graph shows an elongated oval organism that it narrower at the upper right than at the lower left, has organelles inside, and has hair-like cilia all around the outside of its cell membrane. The horizontal axis is labeled days and ranges from 0 to 18, in increments of 2. The vertical axis is labeled number of individuals and varies from 0 to 200, in increments of 50. The curve begins at 0 on the horizontal axis and just above 0 on the vertical axis and rises slowly, then curves upward and runs almost diagonally from (3, 35) to (6, 150). At this point, it curves and levels off to run horizontally from (11,

195) until the curve ends at just before 18 on the horizontal axis and 195 on the vertical axis.

Graph b is labeled italicized P. caudatum end italics grown separately and has the same labels and axes as the graph in part a. An illustration of italicized Paramecium caudatum end italics near the bottom just to the right of the center of the graph is a long oval with organelles inside and hair-like cilia all around the outside of its cell membrane. It is larger than italicized P. end italics aurelia end italics. A curve begins at 0 on the horizontal axis and just above 0 on the vertical axis and begins to rise slowly, then rises almost

diagonally from (2.5, 25) to (6.2, 120). It then curves and levels off to run almost horizontally from (8.2, 140) to (17.2, 140).

Graph c is labeled italicized P. aurelia end italics and italicized P. caudatum end italics grown together and has same labels and axes as the graph in part a. The curve labeled italicized P. aurelia end italics begins at 0 on the horizontal axis and just above 0 on the horizontal axis and rises slowly and then more rapidly. It is almost diagonal from (3.5, 40) to (5.9, 80), then runs at a more gentle diagonal to (12, 149) before leveling off to run horizontally from (12.5, 150) to end at (17.3, 150). The curve labeled

italicized P. caudatum end italics begins at 0 on the horizontal axis and just above 0 on the vertical axis above the curve for italicized P. aurelia end italics. It and rises slowly to the left of the first curve, and then more rapidly to peak at (3.9, 40) just after crossing the first curve and before curving smoothly down to level off and end at (16.2, 5). All data are approximate.

Return to Figure 55.7 Competition between Paramecium species

Extended description for: Figure 55.8 Resource partitioning

The upper graph, part a, has a horizontal axis labeled seed size and a vertical axis labeled number of individuals. Three seeds are depicted beneath the horizontal axis with a small seed at the far left, an intermediate seed in the middle, and a large seed at the far right. Two bell curves are depicted on the graph. The left-hand curve, labeled Species 1 (strong competitor), begins at the origin and peaks at one-third of the way across the horizontal axis and two-thirds of the height of the vertical axis before descending to meet the horizontal axis just to the right of the midline. The right-hand curve, labeled Species 2 (weak competitor), begins at the horizontal axis just to

the left of its midline and rises to a peak at the same height as the left-hand curve before descending to end at the horizontal axis at the right end of the graph. The right-hand curve is slightly wider than the left-hand curve. There is a shaded region where the right end of the left-hand bell curve overlaps the left end of the right-hand bell curve above the medium-sized seed. This shaded region is accompanied by text reading, Competition occurs in the overlap region. An arrow points down to show a similar graph in part b with the curves changed. The left-hand curve for Species 1 is similar to the corresponding curve in the upper graph. The right-hand curve for

Species 2 is now narrower and begins farther to the right, just at the right-hand end of the left-hand curve for species 1. There is no longer a shaded area of overlap. All data are approximate.

Morris, et al., *Biology for the AP® Course*, 1e,
© 2022 BFW High-School Publishers

A horizontal layer of dirt is depicted with plants growing above it and labeled below. Each label provides the time and a description of the plants present. From left to right, the labels and plants are as follows. Field, crabgrass: A small patch of green

grass extends barely above the ground. Year 1, crabgrass, horseweed: There is a layer of short grass extending from left to right across the region of dirt depicted and some taller plants and flowers are visible at the right end. Year 2, ragweed, heath aster: An assortment of relatively short flowering plants is depicted above a grassy layer. Years 3 to 25, broomsedge, perennial flowers, shrubs, pines: A variety of short trees are depicted above a grassy layer. The trees are triangular in shape. There are some assorted short shrubs as well. Years 25 to 100, pine forest, hardwood understory: There are many coniferous trees above a layer of soil and a few shrubs without a

grassy layer. Years 100 to 200, remnant pines with young oak and hickory trees: There are diverse trees present including some pines. Years 200 plus, oak-hickory climax forest: There is an assortment of trees with some grasses below.

Return to Figure 55.12 Terrestrial succession in abandoned farm fields

Extended description for: Figure 55.13 Stream succession

Graph a shows how algae reappeared following a flood that left only bare rocks and sand. The horizontal axis is labeled days after flooding and ranges from 0 to 70, in increments of 10. The vertical axis is labeled stream cover (percent) and ranges from 0 to 100, in increments of 20. Four curves are

depicted on the graph. The curve labeled bare sand begins at (1, 70) and drops diagonally to end at (12, 0). The curve labeled diatoms begins at (2, 30) and increases to (14, 98), then increases slightly to (22, 99), then decreases to (32, 61), then decreases to (50, 42), then decreases to end at (53, 22). The curve labeled cyanobacteria begins at (22, 1) and rises to (32, 36), then decreases slightly to (48, 30), then increases to end at (53, 42). The curve labeled green algae begins at (33, 2) and increases to (48, 21), then increases to end at (52, 29).

Graph b shows the reappearance of invertebrate animals after flooding.

The horizontal axis is labeled days after flooding and ranges from 0 to 70, in increments of 10. The vertical axis is labeled number of invertebrate animals and ranges from 0 to 300, in increments of 50. The curve begins at (0, 0) and increases to (5, 20), then increases to (13, 40), then increases to (21, 99), then increases to (34, 103), then increases to (48, 250.5), then increases to end at (53, 280). All data is approximate.

Return to Figure 55.13 Stream succession

Extended description for: A graph compares the number of individuals over time for two species living alone or with the other species

The horizontal axis is labeled time (months) and ranges from 0 to 7, in

increments of 1. The vertical axis is labeled number of individuals and ranges from 0 4o 400, in increments of 50. Points are plotted on the graph for four different conditions, and each set of points is connected to the others of the same set to form four diagonal lines that begin and end at these points. The line for species A, when living with species B, begins at (0, 125) and ends at (6, 300). It runs through the following points: (0, 125), (2,185), (3, 220), (4, 249), (5, 240), and (6, 300). The line for species A when living alone begins at (0, 120) and ends at (6, 198). It runs through the following points: (0, 120), (1, 140), (2,149), (3, 151), (4, 153), (5, 177), and (6, 198). The line for species B when

living alone begins at (0, 115) and ends at (6, 151). It runs through the following points: (0, 115), (1, 123), (2,138), (3, 140), (4, 149), (5, 149.5), and (6, 151). The line for species B, when living with species A, begins at (0, 116) and ends at (6, 360). It runs through the following points: (0, 116), (1, 152), (2, 200), (3, 248.5), (4, 280), (5, 320), and (6, 365). The graph clearly shows that both species, but especially species B, are more abundant when living together. All data are approximate.

Return to A graph compares the number of individuals over time for two species living alone or with the other species

Extended description for: A figure shows a visual synthesis of ecological succession in an aquatic community and the effects of factors in the surrounding environment.

A figure shows a visual synthesis of ecological succession in aquatic and terrestrial communities and the effects of factors in the surrounding environment

The figure shows a grassy area with cows and a farm in the background and with water in the foreground that is cut away to show the organisms inside. Text in a box at the upper left reads, “Human impact. Water running off farm fields and home lawns can carry nutrients that cause pond succession to happen more rapidly.” Text in a box at the upper right reads, “Population growth. When organisms first colonize a pond, their populations increase exponentially until competition for

food and space slows further growth. Zooplankton and algae increase exponentially, as do the aquatic insect larvae and tadpoles that feed on them." Across the top of the area of focus, there is a right-pointing arrow labeled time. The area of focus is divided into two halves. At the top of the left half, a green arrow labeled runoff points from the farmlands to the land near the water from the farmlands. From the tip of this arrow, an arrow points down into the water and is labeled, excess deposition of N and P. Four circles show close-ups of organisms in the water. At the upper right near the surface, there is zooplankton, and the circle shows Daphnia, which have roughly oval

bodies with short protrusions below and tufts of protrusions from the heads. Many dots representing organisms are in the water below. To the left, another circle at the top of the water is labeled tiny insects and shows a water strider with smaller water striders visible in the water below. To the right, there is a circle showing two algae, each of which has an oval body that narrows toward the end from which two flagella extend outward. Below the algae, three rod-shaped bacteria are illustrated. An arrow labeled Natural deposition of C, N, and P points toward the soil beneath the water. Text below reads, “Colonizing microorganisms, insects, plants, and animals arrive, carried by

the wind or by birds. Some colonizers follow cues of light reflecting from water surfaces as well as breezes carrying humid air." A horizontal bar below shows seven horizontal bars illustrating when different organisms appear. The top bar extends to the far left beneath the left-hand part of the water and is labeled algae, bacteria, and zooplankton. The right-hand part of the water has some dragonflies above and some grass growing up from the bottom. Some small fish are visible. Circles show close-ups of black water beetles and yellowish fly larvae that have long, segmented bodes. A large fish is depicted below approaching a smaller fish with its mouth open. Text below reads, "At

first, populations grow exponentially, unchecked by competition, predation, or dwindling resources." An arrow points from the large fish to a graph. The horizontal axis of the graph is labeled carrying capacity, and the vertical axis of the graph is labeled population size (italicized N end italics). A logistic curve is depicted that begins at the origin and runs horizontally, then curves upward slowly, then runs upward at a sharp angle across the middle of the graph, then curves and levels off to run horizontally until it ends at the right end of the graph at just over three-quarters of the height of the vertical axis. A dashed line extends from the horizontal part of the curve to the

vertical axis and is labeled carrying capacity of environment (italicized K end italics). In the horizontal bar below showing seven bars representing times of appearance, the horizontal bars below show that arthropods and insects, amphibians and fish, and aquatic plants appear at just past the midpoint of the main bar. Grasses and sedges and herbaceous plants appear at three-quarters of the main bar.

A box at the upper left reads, “Species interactions. With increasing diversity comes an increase in the numbers of connections between species as predators, prey, or symbionts. Interactions help to

control population sizes." A box at the upper right reads, "Succession. As forest communities mature and stabilize, shade-tolerant species may only be disrupted by fire or other disturbances. This can set communities back to earlier successional stages. As soils deepen and store the seeds of sun-loving species, they establish themselves in any openings that are created." A grassy area with some trees and woodland in the background and two birds flying above the trees has water in the foreground that is cutaway to show what is underwater. Soil is depicted to the right of this cutout are. An arrow labeled time points from left to right on the land above

the water. Text below the right end of the arrow reads, Human impact. Logging, starting fires (or suppressing natural fires), and introducing invasive species can alter the species composition of the pond as well as adjacent fields and forests. A food web is depicted with arrows connecting animals in the water, on the land, and in the air. Large and small fish are in the water. An arrow points from small dots representing organisms in the water to a bivalve. An arrow points from the same dots to a small fish and an arrow points from leaves to another fish. Two arrows point from two different fish to a heron standing in the water. Arrows point from a water strider to a

fish in front of a leaves, a frog sitting on a lily pad, a mallard duck swimming in the water, a mouse on the shore, and a bird flying above. Arrows from small dots, a small fish, and different water plants also points to the duck. An arrow from grasses also points to the mouse. Arrows from a large fish, the duck, the mouse, and the frog point to a coyote standing on the shore. Arrow from the mouse also points to a hawk. There are worms and other bivalves on the soil under the water. An arrow pointing from the top of the water to the soil is labeled, “Increased accumulation of dead organic matter.” Text below reads, “As plant and animal succession occurs, death

and decomposition lead to the accumulation of organic matter on the pond bottom. When combined with sediments from water running off the land, the pond is gradually converted to a terrestrial ecosystem." To the right, there is a layer of soil that is darker than the soil immediately beneath the water. Accompanying text reads, "The dominant plants change the physical habitat by shading and spurring organic decay, excluding some animals and plants while permitting others to establish." A horizontal segment below shows eight horizontal bars that indicate when different organisms appear. The top six are continuations from the first

half of the visual synthesis. From top to bottom, these bars are as follows: arthropods and insects extend to the first quarter of the large horizontal bar; amphibians and fish extend to two-thirds of the length of the horizontal bar; aquatic plants extend just past the bar for amphibians and fish; grasses and sedges extend almost to the right end of the bar; and herbaceous plants extend almost to the right end of the large bar. The first new bar, terrestrial animals, begins at one-quarter of the length of the large bar and continues almost to its right end. The second new bar, shrubs and trees, begins at one-third the length of the large horizontal bar and continues almost to its right end.

Extended description for: Figure 56.1 Levels of biodiversity

a. Genetic diversity

Morris, et al., *Biology for the AP ® Course*, 1e, © 2022 BFW High School Publishers

b. Species diversity

c. Ecosystem diversity

Part a is labeled genetic diversity and shows three deer, each with a differently colored double helix D N A

running horizontally across its abdomen.

Part b is labeled species diversity and shows a large deer on the right in front of a smaller deer with spots. To their left are mushrooms and then a flowering bush. To the left of the bush is a rabbit. There are trees behind these animals and mountains in the background.

Part c is labeled ecosystem diversity and shows a large-scale view of a valley with a green hill on one side with grass along its right side, then a region of trees containing two pools, then an area with a band of trees before more grass, then a stream,

then a hilly region. There are snow-capped mountains in the background.

Return to Figure 56.1 Levels of biodiversity

Extended description for: Figure 56.3 Artificial selection in crop plants

A photo labeled ancestor, wild mustard shows a plant with relatively large green leaves near its base; long, thin stems; and yellow flowers. Arrows radiate out to indicate that this was the ancestor of six crop

plants. Clockwise from the lower left, the crops are as follows. Brussels sprouts have a cylindrical green base made of many spheres beneath large, somewhat rounded leaves. Cauliflower has a rounded white flower made of smaller rounded parts with large leaves extending around it. Broccoli has a rounded green flower made of smaller rounded parts surrounded by large leaves. Kale has a narrow base that widens into a rounded top made of leaves with ruffled edges. Cabbage has a rounded central region surrounded by a round array of very broad leaves. Kohlrabi has a rounded part at the base from which thin stems extend up to a few leaves of varying sizes.

Return to Figure 56.3 Artificial selection in crop plants

Extended description for: Figure 56.4 Effects of island size on species richness

The horizontal axis is labeled island area (kilometer squared) (log scale) and ranges from 0 to 1,000,000, labeled in logarithmic increments. The vertical axis is labeled number of species (log scale) and ranges from 1

to 100, labeled in logarithmic increments. A positive slope begins at (0, 5) and ends at (1,000,000, 150). The following points are plotted on or adjacent to the line: Redonda (3, 5); Saba (10.5, 7); Montserrat (100, 9.5); Puerto Rico (9000, 70); Jamaica (10,000, 70); Hispaniola (80,000, 90); and Cuba (1000,000, 85). All data are approximate.

Return to Figure 56.4 Effects of island size on species richness

Extended description for: Figure 56.5 Effects of habitat diversity on species richness

The horizontal axis is labeled foliage height diversity and ranges from 0 to 1.5, in increments of 0.5. The vertical axis is labeled bird species diversity and ranges from 0 to 3, in increments

of 1. The following points are plotted on the graph, forming a roughly diagonal pattern from the lower left just below 1 on the vertical axis to a clump of dots around 1.0 on the horizontal axis between 2 and 3 on the vertical axis: (0.05, 0.7), (0.4, 1.3), (0.6, 1.35), (0.7, 1.8), (0.725, 2.2), (0.8, 2.1), (0.82, 2.25), (0.85, 2.4), (1.1, 2.25), (1.1, 2.7), and (1.25, 2.6). All data are approximate.

Extended description for: Figure 56.6 Species diversity in the intertidal zone

Photos: (a) Gary Luhm/DanielDelimont/Newscom; (b) FotoP Images/Alamy Stock Photo

Part a shows a rocky area with thick-bodied starfish close together near a variety of types of seaweed and shelled animals. There are three large rocks to the right, two of which are separated from the foreground rocks and each other by water that also contains a variety of organisms.

Part b shows many mussel shells tightly packed together with water in the background that has large pieces of rocky material jutting out of it. There is a steep, rocky hillside to the right.

Return to Figure 56.6 Species diversity in the intertidal zone

Extended description for: Figure 56.7 Effects of a keystone species on species diversity

The horizontal axis is labeled year and ranges from 1963 to 1973, in increments of 2. The vertical axis is labeled number of species present and ranges from 0 to 25, in

increments of 5. A positive slope labeled keystone predator present begins at (1963, 18) and ends at (1973, 21.5). Two points are plotted on the line: (1963, 18) and (1973, 21.5). A line labeled keystone predator absent begins at (1963, 19) and drops rapidly until 1966, after which it rises slightly before decreasing and leveling off. Five points are plotted on the line: (1963, 19), (1966, 2), (1968, 2.5), (1961, 1), and (1973, 1). All data are approximate.

Return to Figure 56.7 Effects of a keystone species on species diversity

Extended description for: Figure 56.8 Effects of keystone predators being removed from an ecosystem

Part a shows a sea otter lying on its back in the water with its head lifted up and a sea urchin held between its paws on its chest below its mouth.

Part b shows an aquatic environment with many densely packed vertical

strands of kelp making up a healthy kelp forest inhabited by fishes. The fishes have dark upper halves with white rectangular blotches and white lower halves with some dark spots. Their fins are greenish-yellow.

Part c shows a piece of ocean floor covered in yellowish green and a few purple sea urchins, which are round and covered in spines. There are vertical, cylindrical brown structures protruding upward with some urchins on them, but no healthy kelp.

Return to Figure 56.8 Effects of keystone predators being removed from an ecosystem

Extended description for: Figure 56.9 Effects of plant diversity on ecosystem productivity

The horizontal axis of the graph is labeled species diversity (number of species added) and ranges from 0 to 35, in increments of 5. The vertical axis is labeled plant biomass (gram per meter squared) and ranges from 0 to 200, in increments of 20. A curve begins at (0, 0) and rises almost

vertically to (2, 110) before beginning to level off and then leveling off dramatically beginning at (9, 159). Points plotted on the curve with their error bars are as follows: (0, 20 plus or minus 8), (1, 78 plus or minus 10), (2, 110 plus or minus 13), (4, 155 plus or minus 12) above the line, (7.5, 143 plus or minus 10) below the line, (16, 180.5 plus or minus 21) above the line, and (32, 161 plus or minus 10) below the line. All data are approximate.

Return to Figure 56.9 Effects of plant diversity on ecosystem productivity

Extended description for: Figure 56.10 Effects of fungal species richness on ecosystems

All of the graphs have a horizontal axis labeled number of mycorrhizal species that ranges from 0 to 14, in

increments of 2.

Graph a has a vertical axis labeled total shoot biomass (gram per meter squared) that ranges from 70 to 130, in increments of 10. A curve begins at (0, 76) and rises to (10, 120) before beginning to level off and then beginning to descend at (12, 121) to end at (14.1, 119.5). Points on the graph and their error bars are as follows: (0, 76 plus or minus 5), (1, 85 plus or minus 5) above the curve, (2, 81 plus or minus 5) below the curve, (4.1, 98 plus or minus 2) below the curve, (8, 121 plus or minus 4) above the curve, (14.1, 119.5 plus or minus 4) below the curve.

Graph b has a vertical axis labeled total root biomass (gram per meter squared) that ranges from 80 to 160, in increments of 20. A curve begins at (0, 98) and rises to (10, 138) before leveling off to end at (14.1, 139.5). Points on the graph and their error bars are as follows: (0, 85 plus or minus 3) below the curve, (1, 117 plus or minus 4) above the curve, (2, 109 plus or minus 5), (8, 138 plus or minus 5) below the curve, and (14.1, 139.5).

Graph c has a vertical axis labeled total plant phosphorus (gram per meter squared) that ranges from 500 to 2500, in increments of 500. A curve begins at (0, 1200) and rises diagonally to end at (14.1, 1900).

Points on the graph and their error bars are as follows: (0, 1000 plus or minus 20) below the line, (1, 1240 plus or minus 200) above the line, (2, 1400 plus or minus 100) above the line, (8, 1700 plus or minus 200) above the line, and (14.1, 1900 plus or minus 200) below the line.

All data are approximate.

Return to Figure 56.10 Effects of fungal species richness on ecosystems

Extended description for: Figure 56.11 The effects of plant species richness on the stability of a grassland ecosystem

Both graphs have a horizontal axis labeled plant species richness that ranges from 0 to 16, in uneven increments at 0, 1, 2, 4, 8, and 16.

Graph a has a vertical axis labeled stability of herbivore species richness that ranges from 2.6 to 3.8, in increments of 0.2. The graph shows a curve that begins at (1, 2.82) and rises diagonally to (4, 3.48), then decreases slightly before rising slightly to end at (16, 3.55). Points on the graph with their error bars are as follows: (1, 2.82 plus or minus 0.1), (2, 3.02 plus or minus 0.1), (4, 3.48 plus or minus 0.15), (8, 3.42 plus or minus 0.15), and (16, 3.55 plus or minus 0.15).

Graph b has a vertical axis labeled stability of predator or parasitoid richness that ranges from 1.7 to 2.9, in increments of 0.2. The graph shows a curve that begins at (1, 1.95) and rises diagonally to (2, 2.21), then increases slowly to (8, 2.28), then rises diagonally to end at (16, 2.59). Points on the graph with their error bars are as follows: (1, 1.95 plus or minus 0.25), (2, 2.21 plus or minus .01), (4, 2.28 plus or minus 0.1), (8, 2.29 plus or minus 0.8), and (16, 2.59 plus or minus 0.25).

All data are approximate.

of a grassland ecosystem

Extended description for: Figure 56.12 Species richness patterns in vascular plants

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A scale beneath the graph ranges from 0 to over 7500 and is labeled 500, 1000, 1500, 2500, 3500, 5000, and 7500. The highest levels of diversity, often above 5000, are in northern South

America, central Africa, southeast Asia, and the eastern coast of Australia. Moderate amounts of diversity, ranging from 2500 to 5000, are found in other parts of South America in a band along its eastern side excluding the region farthest to the east, in North America, in southern central Africa, and in much of Europe. Relatively low amounts of diversity, generally below 1500, are found in northern Canada, Greenland, a band just below the northern edge of North Africa, Central Asia, Central Australia, and New Zealand. All data are approximate.

Return to Figure 56.12 Species

richness patterns in vascular plants

Extended description for: Figure 56.13 Species richness patterns in mammals

A scale beneath the graph is labeled number of mammal species per 10 kilometer by 10 kilometer grid and ranges from 0 to 267, in uneven increments. The highest levels of

mammal diversity is in a region ranging through Central American through northern and central South America except for a region along the central western side; in southwestern North American extending from the United States into Mexico in much of Africa except for patches in the middle, southwest, and north; and in southeast Asia. These regions have diversity that is often over 154 with a few spots over 242. There is lower diversity elsewhere with the lowest diversity in Alaska, the northernmost parts of Canada, Greenland, central Asia, northwestern Russia, patches of central and southwestern Australia, and Antarctica. All data are approximate.

Return to Figure 56.13 Species richness patterns in mammals

Extended description for: Figure 56.14 Biodiversity hotspots

Morris, et al., Biology: How Life Works AP* Course, 1e, © 2022 BFW High School Publishers

Labeled hotspots are identified in the following regions. California Floristic Province: a narrow patch along the western side of the United States. Mesoamerica: a region extending through Central America into southern Mexico. Caribbean: a patch

over islands in the Caribbean including Cuba as well as the southern tip of Florida. Chocö or Darién or Western Ecuador: A narrow band along the northwestern side of South America. Tropical Andes: A narrow region extending from northern South America to the east of Panama along a curve following the western border of the country but slightly inland and ending in a rounded region in northeastern Argentina. Central Chile: A region along the southwestern coast of South America that ends before the southernmost tip of the continent. Brazil's Atlantic Forest: A narrow region along the east central part of South America. Brazil's Cerrado: A

rounded region in central to southeastern Brazil. Mediterranean Basin: A region along the borders of the Mediterranean. West African Forests: A region along the southern edge of the upper part of African that is wider and extends farther west than the central and lower parts of Africa. Succulent Karoo: A small, narrow region at the southwestern end of Africa. Cape Floristic: A narrow region along the southern edge of Africa. Madagascar: A region encompassing the island of Madagascar and smaller islands around it. Eastern Arc and Coastal Forests of Tanzania/Kenya: Two small regions with one just inland and one along the eastern edge of southern

central Africa. Ethiopia and Somalia: A region on the Horn of Africa and a narrow region on the southern end of the Arabian Peninsula. Caucasus: A region between the Black Sea and the Caspian Sea. Indo-Burma: A region along the western edge of India. Western Ghats and Sri Lanka: A region that includes Sri Lanka. South-Central China: A region in south to central China and extending south into Myanmar, Thailand, and Vietnam. Northwest China: A region including parts of Shaanxi, Ningxia, Gansu, and Qinghai. Sundaland: A region that includes southern Thailand, Malaysia, Singapore, and western Indonesia. Wallacea: A region that includes eastern

Indonesia. Philippines: A region that includes the Philippines. Southwest Australia: A region at the southwestern tip of Australia. Eastern Australia: A region along the eastern edge of Australia. New Caledonia: The island of New Caledonia. Polynesia/ Micronesia: Many islands in the western Pacific east of the Philippines and north of Indonesia, New Caledonia, and New Zealand and extending east to include Hawaii and islands to its southeast. New Zealand: New Zealand and an island to its west toward the south. All data are approximate.

Return to Figure 56.14 Biodiversity hotspots

Extended description for: A graph plots number of species over time with the removal of species X and with the removal of species Y

The horizontal axis is labeled time (months) and ranges from 0 to 70, in increments of 10. The vertical axis is

labeled number of species and ranges from 0 to 140, in increments of 20. The curve labeled Plot 1: species X removed begins at (0, 100) and takes a slightly wavy horizontal path to end at (60, 100). This curve passes through or adjacent to the following points: (0, 100), (6, 100), (12, 98), (18, 97), (24, 98), (30, 99), (36, 99), (42, 100), (48, 102), (53, 102), and (60, 100). The curve labeled Plot 2: species Y removed begins at (0, 100) and descends before reaching (30, 21) and then descending more slowly to (60, 2). This curve passes through or adjacent to the following points: (0, 100), (6, 98), (12, 81), (18, 63), (24, 42), (30, 21), (36, 18), (42, 26), (48, 8), (53, 4), and (60, 2). All data are approximate.

Return to A graph plots number of species over time with the removal of species X and with the removal of species Y

Extended description for: A bar graph plots biomass difference between experimental plots and control plots for a variety of experimental treatments

The horizontal axis is labeled experimental treatment, and eleven different treatments are depicted, color-coded into four groups. The vertical axis is labeled biomass difference between experimental plots and control plots (grams superscript minus 2) and ranges from 0 to 250, labeled in increments of 50. From left to right, the data for the treatments is as follows. The first three treatments are grouped: 1 species of plant, 205; 2 species of plant, 125; and 16 species of plant, 125. The next three treatments are grouped: 95 k g N/h a added, 140; 54 k g N/h a added, 120; and 34 k g N/h a added, 75. The next two treatments are grouped: increased water

availability, 125 and increased CO_2 availability, 70. The next three treatments are grouped: drought, 60; herbivory, 50; and fire, 20. All data are approximate.

Return to A bar graph plots biomass difference between experimental plots and control plots for a variety of experimental treatments

Extended description for: A graph plots number of species of amphibians and reptiles against island area for seven West Indies islands

The horizontal axis is labeled island area (kilometer squared) and ranges

from 0 to 1,200,000, in increments of 20,000. The vertical axis is labeled number of species and ranges from 1 to 90, in increments of 10. A curve begins at (0, 0) and rises rapidly before beginning to slow at (18,000, 38) and then gradually leveling off at (120,000, 88). The points plotted on or near the curve are as follows. Redonda: (0, 1); Saba: (0, 5); Montserrat: (0, 10); Puerto Rico: (8,000, 40); Jamaica: (11,000, 38); Hispaniola: (78,000, 81) above the curve); and Cuba: (108,000, 74) and below the curve. All data are approximate.

Return to A graph plots number of species of amphibians and reptiles

against island area for seven West Indies islands

Extended description for: Figure 57.1 Disrupted ecosystems due to continental drift

In the figure labeled 250 million years ago, all of the continents were close together with the top part forming a solid left-hand portion and islands extending up to the northeast and to the east and with the bottom part forming a large solid portion with a point extending to the center east and

with a narrowing before the very bottom, which is rounded with an oblong eastern portion with two islands to the east and one to the south. The northern part is light green and the southern part is dark green. The entire structure is labeled Pangea.

In the figure labeled 100 million years ago, the upper and lower portions have separated into a light green upper portion labeled Laurasia and a dark green southern region labeled Gondwana. Laurasia has a western portion that resembles a V that is angled to open to the northeast and a large portion to the right with long, thin protrusions to the north and

south from its eastern side. Gondwana has a western region that resembles South America, a central region that resembles Africa but wider, a pointed region to the east, a large island to the lower west, and a smaller island with a curved left side and three protrusions on its right side.

In the figure labeled 60 million years ago, Laurasia has formed a land bridge that angles up from the western edge of the western portion, now labeled and beginning to resemble North America, with Asia to the east. The eastern portion is similar to its previous appearance except that the dark green eastern

protrusion from Gondwana is now joined at its southwestern edge and labeled India. The eastern part of North America joins with Europe with Asia to the right. South America is in its modern position beneath North America, Africa is beneath Europe, the western large southern island is labeled Antarctica, and the eastern southern island is labeled Australia.

Return to Figure 57.1 Disrupted ecosystems due to continental drift

Extended description for: Figure 57.2 Expanding species distributions after glaciers receded

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

Both parts show a map of southeastern Canada and the eastern United States. Text to the lower left reads, “As temperatures rose, the range of jack pines and red pines

shifted northward to their current distribution (dark green).” Text at the center right reads, “Red lines show how the northern limit of these species changed through time.” Text to the lower right reads, “As temperatures rose, hickory expanded its range to its current distribution (light green).”

Part a shows the current and former distributions of jack pines and red pines with an arrow and text indicating that there has been a northward shift in their range. The shaded region showing the modern distribution extends into the northern United States below Lake Superior east toward but not as far as Lake

Michigan, along the northern borders of the other Great Lakes, and south into northern New England. Lines indicate the range boundaries at different times, showing past ranges as follows. 8000 years ago: north of the Great Lakes and the current southern border; 9000 years ago: along northern Lake Superior and then almost directly east; 10,000 years ago: from near the southern boundary of the current range at the west but not extending as far east and running horizontally across the middle of Lake Superior to end around northern Massachusetts to the east; 11,000 years ago: along the current boundary; 12,000 years ago: the line begins near the bottom of a

diagonal line extending from the Florida panhandle through Alabama and Mississippi to end along the current range west of Lake Superior and bends almost vertically upward to curve east beneath Lake Erie and Lake Ontario to end just south of Long Island; 13,000 years ago: the line begins slightly lower on the diagonal than the line from 12,000 years ago, even farther south, and follows a similar path slightly to the south to end by crossing the Chesapeake Bay and southern Maryland.

Part b shows light green covering most of the region depicted on the map except for the western edge running north and slightly west from

western Louisiana and the region above a narrow band of green above the Great Lakes. An arrow pointing to the upper right is labeled hickory expansion. Lines indicate the range boundaries at different times, showing the boundaries as follows. 12,000 years ago: A line begins in northwestern Florida and curves upward and west through the southern and central states to end near the middle of the range in the west; 11,000 years ago: The curve begins in Georgia and runs to the north of the previous line; 10,000 years ago: the line begins in southern North Carolina and curves north across the southern end of Lake Michigan before curving down to end

just above the previous line; 9000 years ago: the line begins by crossing southern Maryland and the Chesapeake Bay and runs almost horizontally, then curves north across lake Erie and central Lake Michigan before curving slightly south before ending; 8000 years ago: the line begins in New Jersey and runs almost horizontally west across Lake Erie and Lake Michigan before bending to the south at the far west; 7000 years ago: the line begins by crossing Long Island and runs west across northern Lake Erie and southern Lake Huron across Lake Michigan before bending down near the end to end just above the boundary from 8000 years ago; 5000 years ago: the line begins around

northern Massachusetts close to the current northern boundary and runs across the top of Lake Ontario, through Lake Huron, across the top of Lake Michigan, and west beneath lake Superior before ending just west of the southwestern end of Lake Superior. All data are approximate.

Return to Figure 57.2 Expanding species distributions after glaciers receded

Extended description for: Figure 57.5 The gain and loss of forested habitats around the world

There are no change areas in much of North American and Central America, Cuba, and South America. There is gray in vertical regions to the east of a narrow band along the Pacific Coast of the United States

extending down to Baja California. This connects around the border of the United States and Mexico to a vertical gray region that extends through central Mexico and north into Canada. The patchy areas between these gray regions contain many spots of tree gain and tree loss. The band along the Pacific shows many spots of tree gain and tree loss. Central Canada has many tree loss areas just north of many tree gain areas with no change regions to their north. These tree gain and tree loss areas follow a pattern beginning with a tree loss region surrounded by no change in central Alaska that runs southwest and begins increasingly marked with tree gain toward central

Canada in the region where southwestern Canada meets the northwestern United States. This pattern continues from central Canada through a no change region before reaching a tree gain region above Lake Superior with many tree loss spots around it, especially to the south and west. The region above the Great Lakes has a band of tree gain with some tree loss around the edges extending to the eastern end of Canada and south through New England with large amounts of tree gain from Maine in the United States into New Brunswick in Canada. There is tree loss around this tree gain region. There are many spots of tree loss along the region of the United

States extending south to the east of the Great Lakes and then extending west through the south and midsouthern regions. There is tree loss along the top, then a considerable amount of tree gain in the center and south of this region extending through the upper half of the Florida peninsula. In Central America, there is considerable tree loss with tree gain on the Yucatan peninsula. Cuba has two large areas of tree gain, some smaller areas of tree gain, and areas of tree loss and no change. Northeastern South American has some tree loss and some tree gain that extends just inland along the northwest side. To the east, there is a large amount of

tree loss extending near the bottom of the widest part of South America but extending upward into some tree gain regions above the part of Brazil that protrudes to the east. There is a triangular colored region below along the eastern and central part of South America that represents tree loss to the west and tree gain to the east with no change below. The southwestern region along the Pacific is tree gain near the center and then no change below. African is mostly gray with an area at the southwest of the wider northern portion that is tree loss with no change around it and some tree gain to the southwest. This region is joined by a no change region with tree loss spots to a large colored

region in the center extending south to a large gray region. This colored region has no change around the edges, many tree loss spots in the rest, and areas of tree gain in the middle. Along the southeastern cost, there is a tree loss region with some tree gain to the north. Along the southeastern coast, there is a tree gain region that becomes tree loss as it curves to form the southernmost point. Madagascar to the east has tree loss to the west central, no change above, and tree gain along the north and eastern sides with tree loss between these tree gain regions and the ocean. Europe is bordered in no change with tree gain along northern Spain and in Portugal and from

Sweden and Finland along a band west through Russia. This band extends east and west and contains many areas of tree loss with concentrated areas of tree gain. Southeast Asia has many regions of tree loss with some tree gain, Indonesia has many tree gain regions. Papua New Guinea is no change. The outer borders of most of Australia are no change but the center and most of the western side is gray. The southwest has a tree loss region along the coast with tree gain at the southwestern-most point. The eastern coast is mostly no change with tree loss and tree gain to the southeast that is more tree gain along the southern edge. Tasmania to the south

has spots of tree loss and tree gain. New Zealand has a large amount of tree gain in the North Island with some tree loss to the east and south. The South Island of New Zealand has tree gain and tree loss at its northern end and a tree gain region at its southern end.

Return to Figure 57.5 The gain and loss of forested habitats around the world

Extended description for: Figure 57.8 The overharvesting of cod

The horizontal axis is labeled year and ranges from 1860 to 2000, in increments of 20. The vertical axis is labeled tons of cod caught and ranges

from 0 to 900,000, in increments of 100,000. The curve begins at (0, 110,000) and follows a jagged gradual upward path until (1960, 240,000). At this point, the curve peaks at (1962, 159,000), drops slightly, and then peaks at (1967, 805,000) before dropping dramatically to (1976, 140,000), rising slightly to (1980, 250,000) to start a short horizontal jagged period before dropping to (1980, 40,000) and then to (1992, 0) and running in a jagged line along the horizontal axis to the right end of the graph. All data are approximate.

Return to Figure 57.8 The overharvesting of cod

Extended description for: Figure 57.10 The greenhouse effect

The sun is depicted with two arrows pointing away from it representing solar radiation. One arrow points down to the ocean, and the other

points up into space. Just to the right of the place that the solar radiation hits the ocean, two arrows point diagonally up to the right. The first arrow, labeled heat, points into the atmosphere. The second arrow points up to hit a C O 2 molecule, depicted as a space-filling model with a silver sphere that has a red sphere on each side. Many additional C O 2 molecules are illustrated behind it. From the C O 2 molecule, one arrow points into the atmosphere, another arrow labeled heat points horizontally beneath the layer of C O 2 molecules and toward a beachfront with buildings and with mountains behind it, and a third arrow points down to the shore.

Extended description for: Figure 57.11 The Keeling curve of increasing CO2mathml alt text in the atmosphere

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High-School Publishers

The horizontal axis is labeled year and ranges from 1960 to 2020, in increments of 10. The vertical axis is labeled C O 2 concentration (parts per million) and ranges from 310 to 420, in increments of 10. A jagged diagonal line begins at (1960, 318) and steadily increases to end at (2022, 419). Accompanying text reads, “Atmospheric levels of C O 2 have steadily increased over the last 60 years.” A close-up of the very end of the curve plots the C O 2 concentration by month. The horizontal axis is labeled month and ranges from April 2019 to April 2021 in increments of 3 months. The vertical axis is labeled C O 2 concentration and ranges from 405 to

420, in increments of 5. A curve begins at (April 2019, 414) and rises to (May 2019, 415), then decreases through a series of points to (October 2019, 408), then rises in a relatively smooth pattern to peak at (May 2020, 417), then decreases to (September 2020, 412) and stays at 412 through October before rising to (April 2021, 419) and staying at 419 in May 2021. Text to the left reads, “C O 2 concentrations regularly cycle up and down over the course of a year.” All data are approximate.

Extended description for: Figure 57.12 Global warming around the world

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A scale below the graph is labeled temperature change (Kelvin) and includes the following categories from left to right: negative 2 to negative 1, negative 1 to 0, 0 to 1, 1 to 2, 2 to 2.5, and 2.5 to 3. There are

some regions representing temperature, decreases just north of and around Antarctica and just west of Central America, but most of the map shows temperature increases. The only regions showing a decrease greater than negative 1 are two small areas near Antarctica. Most of Antarctica is shaded to represent 1 to 2 degrees of warming with two patches that show 2 to 2.5. One of these warmer patches has a center showing 2.5 to 3. Most of the rest of the oceans show 0 to 1 degree of warming with some oblongs representing 1 to 2 degrees in the northern and southern Atlantic, Indian Ocean west of Australia, and Pacific Ocean east of Japan. North

American shows 1 to 2 degrees of warming except for the northern center and west between the northern United States and northern Canada. Northern Canada into Alaska shows a band of 1 to 2 beneath a band of 2 to 2.5 beneath a band of 2.5 to 3 that extends across the Arctic. Warming of 2.5 to 3 is found in small areas to the northeast of Canada extending onto Greenland, which has the same amount of warming, and in a small region southeast of Manhattan surrounded by a region of 2 to 2.5 that extends up to meet the band of this temperature difference running through northern Canada. A group of Islands in the north Atlantic is 1 to 2, but most of the Atlantic

south of Greenland is 0 to 1. The Caribbean is 0 to 1. Mexico is 1 to 2 except for its southernmost regions and the Yucatan peninsula, which are 0 to 1. Central America is 0 to 1, as is northern and western South America and the easternmost tip of Brazil. There is a vertical band of 1 to 2 from northeastern South American through Brazil into the ocean south of Brazil. Ireland, the northern United Kingdom, Spain, and the eastern part of France are at 1 to 2, then there is a region of Europe at 2 to 2.5. The band at 2.5 to 3 in the Arctic extends down over all of Scandinavia except for the westernmost part and south into continental Europe. There is another patch of 2.5 to 3 in Saudi Arabia.

Africa is 1 to 2 except for the northwestern region and southeast, which are 0 to 1. Asia is mostly 1 to 2 except for 0 to 1 in Indian and southeast Asia and a patch northwest of the Caspian Sea and 2 to 2.5 in a region in central Asia. Southeast Asia is mostly 0 to 1 except for an area of islands east of Papua New Guinea and central to southeastern and central eastern Australia that is 1 to 2. All data are approximate.

Return to Figure 57.12 Global warming around the world

Extended description for: Two graphs compare percent change in net calcification in control and experimental groups of a reef with part a showing the effects of increased p H and part b showing the effects of decreased p H

Part a is labeled increased p H. The

horizontal axis shows two labels for the bars on the plot, with control on the left and experimental on the right. The vertical axis is labeled percent change in net calcification and ranges from negative 4 to 10, in increments of 2. A dark horizontal line extends from 0 on the vertical axis, and the bars showing the data extend up and down from it. The bar for the control group is negative 0.5 plus or minus 2, and the bar for the experimental group is 6.4 plus or minus 1.

Part b is labeled decreased p H. The horizontal axis shows two labels for the bars on the plot, with control on the left and experimental on the right. The vertical axis is labeled percent

change in net calcification and ranges from negative 40 to 0, in increments of 10. The bar for the control group is negative 2 plus or minus 6, and the bar for the experimental group is negative 35 plus or minus 8.

All data are approximate.

Extended description for: Figure 57.13 Protecting habitats

Morris, et al., *Biology for the AP* Course*, 1e, © 2022 BFW High School Publishers

Part a is labeled terrestrial. The horizontal axis is labeled year and ranges from 1960 to 2020, in increments of 10. The vertical axis is labeled percentage land area protected that ranges from 0 to 20, in increments of 5. A curve begins at (1960, 2) and rises slowly and slightly unevenly before beginning to level off at (2009, 14) and then becoming almost horizontal before ending at (2020, 15).

Part b is labeled marine. The horizontal axis is labeled year and ranges from 1960 to 2020, in increments of 10. The vertical axis is labeled percentage ocean area protected and ranges from 0 to 8, in

increments of 1. The curve begins at (1960, 0) and runs almost horizontally before beginning to rise slowly just after 1970 to reach (2004, 0.8) before rising more rapidly to (2010, 1.7), then rising almost diagonally to (2018, 7.2) and then at a shallower diagonal to (2020, 7.6).

All data are approximate.

Return to Figure 57.13 Protecting habitats

Extended description for: A graph plots number of extinctions and the human population by year

The horizontal axis is labeled year and ranges from 1800 to 2010, in increments of 30. The left-hand vertical axis is labeled number of extinctions (thousands) and ranges from 0 to 60, in increments of 10. The

right-hand vertical axis is labeled human population (billions) and ranges from 0 to 8, in increments of 1. Two curves are plotted on the graph. The first curve is labeled human population. It begins at (1800, 1.1) and rises slowly until (1935, 2.7) when it runs horizontally before it reaches (1949, 2.7), and then rises diagonally to end at (2011, 7.5). The second curve is labeled extinctions. It begins at (1800, 0) and runs almost horizontally, with a very slight increase to (1930, 3), before rising to (1949, 8), and then rising rapidly with a slight bump to end at (2011, 55). All data are approximate.

Return to A graph plots number of

extinctions and the human population by year

Extended description for: A graph plots proportion of high-quality nest sites occupied by italicized P. major end italics against average December temperature

The horizontal axis is labeled average December temperature (Degrees

Celsius) and ranges from 0 to 10, in increments of 2. The vertical axis is labeled proportion of high-quality nest sites occupied by italicized P. major end italics and ranges from below 0.20 to 0.45, in increments of 0.5. Five points are plotted on the graph as follows: (1, 0.265); (2.8, 0.29), (3.8, 0.26), (5.9, 0.30), and (9.6, 0.37). All data are approximate.

Return to A graph plots proportion of high-quality nest sites occupied by italicized P. major end italics against average December temperature

Extended description for: A graph plots Simpson's diversity index against temperature

The horizontal axis is labeled temperature (degrees Celsius) and ranges from 0 to 30, in increments of 10. The vertical axis is labeled Simpson's diversity index and ranges

from 0 to 1.0, in increments of 0.2. Points are plotted on the graph as follows: (4, 0.2), (8, 0.3), (10, 0.6), (11, 0.6), (13, 0.7), (16, 0.77), (17, 0.56), (20 0.71), (20, 0.805), (20, 0.905), (22, 0.79), and (25, 0.805). All data are approximate.

Return to A graph plots Simpson's diversity index against temperature

Extended description for: A graph plots average population count of harbor seals by year to produce a population growth curve

The horizontal axis is labeled year and ranges from below 1975 to 2020, in increments of 10. The vertical axis

is labeled average population count and ranges from 0 to 6000, in increments of 1000. A curve begins at (1974, 400) and curves upward slowly beneath a point labeled A at (1978, 900) before beginning to rise more rapidly through an area where there are many points above and below between (1983, 1800) and (1992, 3800). The curve begins to level off just above this point with four points above and three below. It levels off even more by (200, 4700) and begins to run horizontally at (2005, 5000) until it ends at (2018, 5000) just below a point at (2019, 5100). The following points are on the graph in addition to point A at (1978, 900): (1983, 1700), (1984, 2200), 1985, 1950), (1986, 2100),

(1987, 2099), (1988, 2900), (1989, 2999), (1990, 3100), (1991, 3250), (1992, 3300), (1993, 4500), (1994, 4500), (1995, 4900), (1996, 5200), 1997, 4200), (1998, 4300), (1999, 3300), and (2019, 5100). All data are approximate.

Return to A graph plots average population count of harbor seals by year to produce a population growth curve

Extended description for: A bar graph compares the numbers of four species observed within a reserve in 2000 versus 2020

The horizontal axis is labeled species. From left to right, it shows values for 2000 and 2020 for African elephant,

lion, impala, and woody trees. The vertical axis is labeled number observed within reserve area and ranges from 0 to 700, in increments of 100. The values in the bars are as follows. African elephant: 2000, 63 plus or minus 5; 2020, 45 plus or minus 5. Lion: 2000, 29 plus or minus 11; 2020, 19 plus or minus 11. Impala: 2000, 127 plus or minus 6; 2020, 89 plus or minus 11. Woody trees: 2000, 431 plus or minus 65; 2020, 620 plus or minus 70. All data are approximate.

Return to A bar graph compares the numbers of four species observed within a reserve in 2000 versus 2020

Extended description for: A graph plots percent resistance of italicized Streptococcus pneumonia end italics against two antibiotics over a ten-year period

The horizontal axis is labeled year and ranges from 1994 to 2004, in increments of 1. The vertical axis is

labeled percent resistance and ranges from 0 to 8, in increments of 1. The curve for co-trimoxazole passes through the following points: (1994, 4.45), (1995, 5.4), (1996, 4.5), (1997, 4.9), (1998, 4.9), (1999, 6.8), (2000, 6), (2001, 5.9), (2002, 7.4), (2003, 8), and (2004, 7.1). The curve for erythromycin passes through the following points: (1994, 1.5), (1995, 2), (1996, 1.6), (1997, 1.9), (1998, 3.1), (1999, 2.9), (2000, 3), (2001, 3.4), (2002, 4.1), (2003, 5.6), and (2004, 4.9). All data are approximate.

Return to A graph plots percent resistance of italicized Streptococcus pneumonia end italics against two antibiotics over a ten-year period

Extended description for: A graph plots number of butterflies in patch A by year

The horizontal axis is labeled year and ranges from 0 to 8, in increments of 1. The vertical axis is labeled number of butterflies in patch A and ranges from 0 to 300, in increments of

50. The curve begins at (0, 0) and rises slowly to (0.2, 2), then curves upward to rise almost diagonally to (3.9, 190). It begins to level off and runs horizontally from (5.1, 225) to end at (8, 225). All data are approximate.

Return to A graph plots number of butterflies in patch A by year

Extended description for: A figure shows a food web above a table listing the species and the number of each species in the sampling area

Species	Number of individuals in sampling area
Panicum virgatum	1863
Impatiens capensis	367
Peromyscus maniculatus	295
Sylvilagus floridanus	118
Odocoileus virginianus	26
Vulpes vulpes	18
Canis latrans	10
Buteo jamaicensis	4
Total	**2701**

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A food web is depicted with arrows connecting species. All species names are italicized. Impatiens capensis is at the lower left with arrows pointing to Odocoilus virginianus at the upper left, Sylvilagus floridanus at the slight upper right, and Peromyscus maniculatus at the far upper right. Panicum virgatum is at the lower right with arrows pointing to Odocoileus virginianus at the upper left, Sylvilagus floridanus at the slight upper left, and Peromyscus maniculatus above. Odocoileus virginianus has an arrow pointing up to Canis latrans. Sylvilagus floridanus has arrows pointing to Canis latrans at the upper left, Buteo jamaicensis above, and Vulpes vulpes to the upper

right. Peromyscus maniculatus has arrows pointing to Canis latrans at the upper left, Buteo jamaicensis at the slight upper left, and Vulpes vulpes above.

The table has two columns and nine rows. From left to right, the columns are labeled species and number of individuals in sampling area. The data in the rows are as follows. Row 1: species Panicum virgatum, number 1863. Row 2: species Impatiens capensis, number 367. Row 3: species Peromyscus maniculatus, number 295. Row 4: species Sylvilagus floridanus, number 118. Row 5: species Odocoileus virginianus, number 26. Row 6: species Vulpes

vulpes, number 18. Row 7: species Canis latrans, number 10. Row 8: species Buteo jamaicensis, number 4. Row 9: total, number 2701.

The column headers read, first position (5 prime end), second position, and third position (3 prime

end). The table shows the codon on the first position (5 prime end) as U, C, A, and G from top to bottom in the first column. The second position codons are U, C, A, and G from left to right in the second column. The third position (3 prime end) codon are U C A G, U C A G, U C AG, and U C A G from the top to bottom in the third column.

The data in U-First position 5 prime end, second position- U, reads as follows: U U U, Phe; U U C, Phe; U U A, Leu; and U U G, Leu. The data in U, C reads: U C U, Ser; U C C, Ser; U C A, Ser; and U C G, Ser. The data in U, A reads: U A U, Tyr; U A C, Tyr; U A A, Stop; and U A G, stop. The data in U, G

reads: U G U, Cys; U G C, Cys; U G A-stop; and U G G, Trp.

The data in C-First position 5 prime end, second position- U, reads: C U U, Leu; C U C, Leu; C U A, Leu; and CUG, Leu. The data in C, C reads: C C U, Pro; C C C, Pro; C C A, Pro; and C C G, Pro. The data in C, A reads: C A U, His; C A C, His; C A A, Gln; and C A G, Gln. The data in C, G reads: C G U, Arg; C G C, Arg; C G A, Arg; and C G G, Arg.

The data in A-First position 5 prime end, second position- U, reads: A U U, lle; A U C, lle; A U A, lle; and A U G, Met. The data in A, C reads: A C U, Thr; A C C, Thr; A C A, Thr; and A C G,

Thr. The data in A, A reads: A A U, Asn; A A C, Asn; A A A, Lys; and A A G, Lys. The data in A, G reads: A G U, Ser; A G C, Ser; A G A, Arg; and A G G, Arg.

The data in G-First position 5 prime end, second position- U, reads: G U U, Val; G U C, Val; G U A, Val; and G U G, Val. The data in G, C reads: G C U, Ala; G C C, Ala; G C A-Ala; and G C G, Ala. The data in G, A reads: G A U, Asp; G A C, Asp; G A A, Glu; and G A G, Glu. The data in G, G reads: G G U, Gly; G G C, Gly; G G A, Gly; and G G G, Gly.

Extended description for: A figure shows a plant releasing and absorbing water

An illustration of a tree shows a series

of arrows entering from the branched roots, traveling through the trunk, and exiting from the tree leaves. The sun shines brightly on the top. Text to the right of the roots reads, root p s i equals negative 0.10 bar. Text to the right of the trunk reads, stem p s i equals negative 1.00 bar. Text to the right of the leafy upper part of the tree reads, leaf p s i equals 2.00 bar.

Return to A figure shows a plant releasing and absorbing water

Extended description for: A figure shows four sets of two molecules each, which are connected by hydrogen bonds and labeled a through d

Morris, et al., Biology for the AP* Course, 1e, © 2022 BFW High School Publishers

Part a: The left-hand molecule is labeled cytosine, and the right-hand

molecule is labeled guanine. Cytosine is a five-membered ring with O at its top vertex; an upper left vertex bonded to C H 2 that is further bonded; a lower right vertex bonded to O further bonded to P double bonded to O to the right, bonded to O below, and bonded to O minus to the left; and an upper right vertex that is bonded to N substituted for C at the lower left vertex of a six-membered ring. The six-membered ring also has double bonds at its upper left and right sides, an upper right vertex bonded to N H 2 that has a hydrogen bond to O double bonded to the upper left vertex of a six-membered ring of guanine, N substituted for C at its right side vertex that has a hydrogen

bond to H bonded to N substituted for C at the left side vertex of guanine, and a lower right vertex double bonded to O that has a hydrogen bond to an H of N H 2 of guanine. Guanine has a six-membered ring on the left with a double bond at its upper right side shared with the lower left side of a five-membered ring, N substituted for C at its lower right vertex, a double bond at its bottom side, a lower left vertex bonded to N H 2 with one hydrogen forming a hydrogen bond to oxygen of cytosine, N substituted for C at its left side vertex and bonded to H that is hydrogen bonded to N of cytosine, and an upper left vertex double bonded to O that is hydrogen bonded to cytosine. The

five-membered ring has a double bond at its lower left side shared with the six-membered ring, N substitute for C at its top vertex, a double bond at its upper right side, nothing bonded to its upper right vertex at the other end of the double bond from N, and N substituted for C at its lower right vertex that is further bonded to the lower left vertex of a five-membered ring with O substituted for C at its bottom vertex, a lower right vertex bonded to C H 2 that is further bonded, and an upper right vertex bonded to O further bonded to P bonded to O minus to the right, bonded to O above that is further bonded, and double bonded to O to the left.

Part b: The left-hand molecule is labeled cytosine, and the right-hand molecule is labeled adenine. Cytosine is a five-membered ring with O at its top vertex; an upper left vertex bonded to C H 2 that is further bonded; a lower right vertex bonded to O further bonded to P double bonded to O to the right, bonded to O below, and bonded to O minus to the left; and an upper right vertex that is bonded to N substituted for C at the lower left vertex of a six-membered ring. The six-membered ring also has double bonds at its upper left and right sides, an upper right vertex bonded to N H 2 that has a hydrogen bond to N H 2 bonded to the upper left vertex of adenine, N substituted

for C at its right side vertex that has a hydrogen bond to H bonded to N substituted for C at the left side vertex of guanine, and a lower right vertex double bonded to O. Adenine has a six-membered ring on the left with a double bond at its upper right side shared with the lower left side of a five-membered ring, N substituted for C at its lower right vertex, a double bond at its bottom side, nothing bonded to its lower left vertex, N substituted for C at its left side vertex and bonded to H that is hydrogen bonded to N of cytosine, and an upper left vertex bonded to N H 2 that has a hydrogen bond to N H 2 bonded to the upper right vertex of cytosine. The five-membered ring has a double

bond at its lower left side shared with the six-membered ring, N substitute for C at its top vertex, a double bond at its upper right side, nothing bonded to its upper right vertex at the other end of the double bond from N, and N substituted for C at its lower right vertex that is further bonded to the lower left vertex of a five-membered ring with O substituted for C at its bottom vertex, a lower right vertex bonded to C H 2 that is further bonded, and an upper right vertex bonded to O further bonded to P bonded to O minus to the right, bonded to O above that is further bonded, and double bonded to O to the left.

Part c: The left-hand molecule is labeled cytosine, and the right-hand molecule is labeled cytosine. The left-hand cytosine is a five-membered ring with O at its top vertex; an upper left vertex bonded to C H 2 that is further bonded; a lower right vertex bonded to O further bonded to P double bonded to O to the right, bonded to O below, and bonded to O minus to the left; and an upper right vertex that is bonded to N substituted for C at the lower left vertex of a six-membered ring. The six-membered ring also has double bonds at its upper left and right sides, an upper right vertex bonded to N H 2 that has a hydrogen bond to O double bonded to the upper right vertex of the right-

hand cytosine, N substituted for C at its right side vertex that has a hydrogen bond to H bonded to N substituted for C at the left side vertex of the right-hand cytosine, and a lower right vertex double bonded to O that is hydrogen bonded to an H of N H 2 bonded to the lower left vertex of the right-hand cytosine. The right-hand cytosine has a six-membered ring on the left with double bonds at its lower left and right sides, its lower left vertex bonded to N H 2 with an H forming a hydrogen bond with O double bonded to the lower right vertex of the left-hand cytosine, N substituted for C at the left side vertex bonded to H that is hydrogen bonded to N at the right side vertex of the left-

hand cytosine, an upper left vertex double bonded to O that is hydrogen bonded to H of N H 2 bonded to the upper right vertex of the left-hand cytosine, and N substituted for C at the upper right vertex that is further bonded to the lower left vertex of a five-membered ring. The five-membered ring has O at the bottom vertex; a lower right vertex bonded to C H 2 that is further bonded; and an upper right vertex bonded to O further bonded to P bonded to O minus to the right, bonded to O above, and double bonded to O to the left.

Part d: The left-hand molecule is labeled cytosine, and the right-hand

molecule is labeled thymine. Cytosine is a five-membered ring with O at its top vertex; an upper left vertex bonded to C H 2 that is further bonded; a lower right vertex bonded to O further bonded to P double bonded to O to the right, bonded to O below, and bonded to O minus to the left; and an upper right vertex that is bonded to N substituted for C at the lower left vertex of a six-membered ring. The six-membered ring also has double bonds at its upper left and right sides, an upper right vertex bonded to N H 2 that has a hydrogen bond to H N with the N substituted for C at the left side vertex of thymine, N substituted for C at its right side vertex that has a hydrogen

bond to O double bonded to the lower left vertex of thymine, and a lower right vertex double bonded to O. Thymine has a six-membered ring on the left with a double bond at its lower right side, a lower right vertex bonded to C H 3, a lower left vertex double bonded to O that is hydrogen bonded to N at the right center vertex of cytosine, N H substituted for C at the left side vertex with a hydrogen bond to N H 2 bonded to the upper right vertex of cytosine, an upper left vertex double bonded to O, and N substituted for C at the upper right vertex that is bonded to the lower left vertex of a five-membered ring with O substituted for C at its bottom vertex, a lower right vertex bonded to C H 2

that is further bonded, and an upper right vertex bonded to O further bonded to P bonded to O minus to the right, bonded to O above that is further bonded, and double bonded to O to the left.

Return to A figure shows four sets of two molecules each, which are connected by hydrogen bonds and labeled a through d

Extended description for: A vertical piece of membrane with extracellular space on the left and intracellular space on the right has three regions through which different molecules pass

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

In the extracellular space at the upper left of the membrane are many spheres with an arrow pointing through the membrane to a smaller number of the same spheres in the intracellular space. In the middle of the extracellular space is a circular clump of small triangles with an arrow pointing through a central

channel of a structure embedded in the membrane that has rectangular bars above and below the channel. The arrow emerges from the channel to indicate three small triangles in the intracellular space. At the lower left of the extracellular space are two squares with an arrow pointing through a horizontal oval embedded in the membrane to a clump of many squares in the intracellular space.

Extended description for: A figure shows two vertical strands of two nucleotides each with hydrogen bonds connecting the upper pair of nucleotides together and the lower pair of nucleotides together. Some bonds are labeled as A, B, C, or D

Morris, et al., *Biology for the AP® Course*, 1e,
© 2022 BFW High School Publishers

The left-hand strand has an upper five-carbon sugar with an upper vertex and a flat base that has an upper left vertex bonded to a circle labeled P and phosphate, a lower left vertex connected to a circle labeled P of the nucleotide below by a bond labeled A, and an upper right vertex connected to a rectangle labeled base by a bond labeled B. The circle labeled P bonded to the lower left vertex of the upper sugar ring is connected to the upper left vertex of a similar six-membered ring labeled

sugar by a bond labeled D, has a lower left vertex bonded to a circle labeled P, and has an upper right vertex connected to a square labeled base by a bond labeled B. The right-hand strand has an upper five-carbon sugar with a bottom vertex and a flat top with an upper right vertex bonded to a circle labeled P, a lower right vertex connected to a circle labeled P by a bond labeled D, and a lower left vertex connected to a rectangle labeled base by a bond labeled B. The circle labeled P bonded to the lower right vertex of the upper sugar is connected to the upper right vertex of a lower sugar by a bond labeled A. This lower right sugar also has a lower right vertex bonded to a circle

labeled P and a lower left vertex connected to a rectangle labeled base by a bond labeled B. There are dashed lines between the rectangles labeled as bases that connect the two strands. The upper two bases are connected by two dashed lines labeled C, and the bottom two bases are connected by three dashed lines labeled C.

Return to A figure shows two vertical strands of two nucleotides each with hydrogen bonds connecting the upper pair of nucleotides together and the lower pair of nucleotides together. Some bonds are labeled as A, B, C, or D

Extended description for: A figure shows interactions of molecules that regulate the cell cycle

On the left, an oval labeled active cyclin-C D K has right and left

pointing arrows indicating a reversible reaction that forms a similar circle bonded to two circles labeled P, one at the upper right and one at the lower right, labeled inactive cyclin-C D K. The left-hand oval labeled active cyclin-C D K also has an arrow pointing down to two bullet points. The bullets read, “Replication initiation. Entry into mitosis.” Above the right and left pointing arrows connecting the active and inactive forms of cyclin-C D K is a hexagon labeled W e e 1. To the upper right of this hexagon is an oval labeled W e e 1 inhibitors that has a line extending to the lower left to end at a short perpendicular line next to the hexagon labeled W e e 1. Below

the right and left pointing arrows connecting the active and inactive forms of cyclin-C D K is an oval labeled C d c 25. Two ovals are beneath this oval. The bottom oval is labeled C h k 1 inhibitors and has a line extending up to a short perpendicular line just beneath the middle oval, which is labeled C h k 1. The oval labeled C h k 1 has a line extending up to a short perpendicular line just beneath the oval labeled C d c 25.

Extended description for: A figure shows a close-up of the upper part of an intestinal cell

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

A band at the bottom is labeled interior of intestinal cell. Above it is a layer with many long, thin protrusions labeled microvilli that begins at the upper left and descends

to end with a microvillus that contacts the band below. Other microvilli are present behind this front layer of microvilli, forming a dense layer of microvilli above the intestinal cells. The area above the microvilli is labeled lumen.

Return to A figure shows a close-up of the upper part of an intestinal cell

Extended description for: A figure shows a food web including ten species that live in Redwood National Forest

Morris, et al., *Biology for the AP ® Course*, 1e, © 2022 BFW High School Publishers

All of the organism names are enclosed in rectangles with rounded edges. Redwood sorrel is at the lower left with an arrow pointing to Wood

boring beetle to the upper left and an arrow pointing to Grasshopper to the upper right. Wood boring beetle has an arrow pointing to Big brown bat above and an arrow pointing to Douglas squirrel to the upper right. Grasshopper has an arrow up to Douglas squirrel. Both Big brown bat and Douglas squirrel have arrows to Northern spotted owl to the upper right. Northern spotted owl has an arrow to Great horned owl to the upper right. At the lower right, Blue elderberry has an arrow pointing up to Northern flying squirrel, which has an arrow pointing up to Northern spotted owl.

Return to A figure shows a food web

including ten species that live in Redwood National Forest

Extended description for: A graph plots D N A content against time to show how D N A content changes throughout the cell cycle

The horizontal axis is labeled time and is divided into five non-equivalent parts, the first four of which from left to right are numbered

with Roman numerals. Time intervals 1 and 2 are similar in length, and time interval 3 begins just past the midpoint of the horizontal axis. Time interval 3 is one-third the length of the preceding intervals and extends to a point close to two-thirds of the way across the horizontal axis. Time interval Roman numeral 4 is very narrow and ends at approximately three-quarters of the way across the horizontal axis. The right-hand time interval is not labeled. The vertical axis is labeled D N A content and has horizontal lines extending from two labeled points: 2 italicized n end italics at one-third of the height of the vertical axis and 4 italicized n end italics at two-thirds the height of the

vertical axis. A horizontal line begins near the left end of the horizontal axis along the 2 italicized n end italics height on the vertical axis, then angles upward throughout Time interval 2 to reach the 4 italicized n end italics height on the vertical axis at the start of Time interval 3. The line runs horizontally until the end of Time interval 4, at which point it drops vertically to just above the height of the 2 italicized n end italics line and then runs horizontally to the edge of the graph.

Return to A graph plots D N A content against time to show how D N A content changes throughout the cell cycle

Extended description for: A flowchart shows the steps of glycolysis

Morris, et al., *Biology for the AP ® Course*, 1e, © 2022 BFW High School Publishers

The reactions are depicted vertically beginning with glucose at the top. An

arrow labeled hexokinase and accompanied by a curved arrow showing the addition of A T P and loss of A D P points to glucose 6-phosphate. Upward and downward pointing arrows indicating a reversible reaction point from glucose 6-phosphate to fructose 6-phosphate, and an accompanying label reads, phosphoglucose isomerase. Below fructose 6-phosphate, upward and downward pointing arrows labeled phosphofructokinase are accompanied by a curved arrow showing the addition of A T P and loss of A D P and show the production of fructose 1, 6-bisphosphate. Upward and downward pointing arrows labeled aldolase point from fructose

1, 6-bisphosphate to glyceraldehyde 3-phosphate, but these arrows also branch to show a reversible reaction that produces dihydroxyacetone phosphate. Right and left pointing arrows labeled isomerase point from dihydroxyacetone phosphate to glyceraldehyde 3-phosphate. Upward and downward pointing arrows labeled triose phosphate dehydrogenase are accompanied by a curved arrow showing the addition of 2 N A D plus and loss of 2 N A D H plus 2 H plus. This reaction yields 1, 3-bisphosphoglycerate. Upward and downward pointing arrows are labeled phosphoglycerate kinase and accompanied by a curved arrow showing the addition of 2 A D P and

loss of 2 A T P. This yields 3-phosphoglycerate. Upward and downward pointing arrows labeled phosphoglyceromutase indicate the production of 2-phosphoglycerate. Upward and downward pointing arrows labeled enolase are depicted with an arrow curving away from the downward arrow to show the loss of 2 H 2 O. This yields phosphoenolpyruvate. Upward and downward pointing arrows labeled pyruvate kinase are accompanied by a curved arrow showing the addition of 2 A D P and loss of 2 A T P. This yields pyruvate.

Return to A flowchart shows the steps of glycolysis

Extended description for: A graph plots molecular abundance against time to show how levels of glucose, pyruvate, fructose 6-phosphate, glucose 6-phosphate, and fructose 1, 6-bisphosphate change over 90 minutes

The horizontal axis is labeled time (minutes) and ranges from 0 to 90, in increments of 30. The vertical axis is labeled molecular abundance (millimoles) and ranges from 0 to 100, in increments of 20. An arrow pointing down at the vertical axis is labeled glucose added. An arrow at 30 minutes indicates that 3 P O is added. An arrow at 60 minutes indicates that additional glucose is added. Curves for five molecules are depicted on the

graph. For glucose, a solid curve begins at (0, 100) and drops diagonally to (60, 55), then rises vertically to (60, 100) when glucose is added, then descends diagonally to end at (90, 78). For pyruvate, a dashed curve begins at (0, 1) and rises diagonally to (30, 50), then runs horizontally from (30, 50) to (60, 50), then increases diagonally to end at (90, 65). For fructose 6-phosphate, a pale curve runs horizontally from (0, 2) to (30, 0), then rises diagonally to (60, 25), then rises diagonally at a shallower angle to end at (90, 40). For glucose 6-phosphate, a dotted curve begins at (0, 2) and increases at a shallow diagonal to end at (90, 8). For fructose 1, 6-bisphosphate, a pale

dashed curve begins at (0, 0.5) and increases at a shallow diagonal to end at (90, 5). All data are approximate.

Return to A graph plots molecular abundance against time to show how levels of glucose, pyruvate, fructose 6-phosphate, glucose 6-phosphate, and fructose 1, 6-bisphosphate change over 90 minutes

Extended description for: A figure shows how the body responds to changes in glucose concentration to maintain the set point of glucose in the blood

The figure consists of a series of text boxes connected by arrows. The

central box reads, “Set point of glucose level in blood (0.9 milligrams per milliliter).” Arrows point up from its left and right sides. The left-hand arrow points to a box reading, “Glucose level in blood increases after a meal,” from which an arrow curves up and then down to point to the first of three boxes on the left side that each contain text. From top to bottom, these boxes read, “Insulin is released into blood by the pancreas; Liver cells convert glucose to glycogen; and Glucose level in blood decreases.” From this bottom box, an arrow curves down and then up to point back to the central box describing the set point of glucose level in blood. The right-hand arrow

points to a box reading, “Glucose level in blood decreases during energy expenditure,” from which an arrow curves up and then down to point to the first of three boxes on the right side that each contains text. From top to bottom, these boxes read, “Glucagon is released into blood by the pancreas; Liver cells convert glycogen to glucose; Glucose level in blood increases.” From this bottom box, an arrow curves down and then up to point back to the central box describing the set point of glucose level in blood.

Return to A figure shows how the body responds to changes in glucose concentration to maintain the set

point of glucose in the blood

Extended description for: Four graphs labeled a through d plot level of insulin and glucagon against glucose level in the blood

Morris, et al., *Biology for the AP * Course*, 1e, © 2022 BFW High School Publishers

All of the graphs have the same horizontal and vertical axes. The horizontal axis is labeled glucose level in the blood (milligrams per milliliter) and ranges from 0 to 2.4, in increments of 0.4. The vertical axis is labeled levels of insulin and glucagon.

Graph a: The curve for insulin begins at (0, 0) and rises rapidly to 0.4 and one-eighth of the height of the vertical axis, then rises more slowly until it begins to level off at 1.2 near the top of the horizontal axis before running horizontally to end at 2.4 near the top of the vertical axis. The curve for glucagon begins at 0 near the top of the vertical axis and descends slowly very briefly to 0.2,

then descends almost vertically to 0.4 just above the horizontal axis before curving to run horizontally along the horizontal axis to end at (2.4, 0).

Graph b: The curve for insulin begins at (0, 0) and runs horizontally along the horizontal axis until it begins to rise at 0.4. It rises slowly from 0.4 to 0.8, at which point it is at one-eighth the height of the vertical axis, then runs at a steep diagonal to 1.3 near the top of the vertical axis. It then levels off and begins to run horizontally at 2.0 until it ends at 2.4 near the top of the vertical axis. The curve for glucagon is similar but begins to curve upward at 0.9, begins to rise more steeply at 1.2, and begins

to level off at 1.7 at three-quarters of the height of the vertical axis before curving to end at 2.4 at three-quarters of the height of the vertical axis. From the time the curve for glucose begins to rise, it is above the curve for glucagon.

Graph c: The curve for insulin is a diagonal line that begins at 0 near the top of the vertical axis and runs downward to end at 2.4 at the bottom of the horizontal axis. The curve for glucagon begins at 0 at the bottom of the vertical axis and runs diagonally up to end at 2.4 at the top of the vertical axis.

Graph d: The curve for insulin begins

at 0 at the bottom of the horizontal axis and runs horizontally along the axis until it begins to curve upward at 0.8 and then begins to rise more rapidly at 1.1 and one-eighth of the height of the vertical axis. It begins to level off at 1.6 near the top of the vertical axis and curves to run horizontally to end at 2.4 near the top of the vertical axis. The curve for glucagon begins at 0 near the top of the vertical axis and curves down slowly to 0.4, then drops rapidly until it begins to curve at 0.8 near the horizontal axis. It then curves and levels off to run horizontally along the horizontal axis from 1.2 to 2.4. All data are approximate.

Return to Four graphs labeled a through d plot level of insulin and glucagon against glucose level in the blood

Extended description for: A figure shows the gametes produced from a parental cell with 2 italicized n end italics equals 4

A large circle at the top center is labeled parental cell, 2 italicized n

end italics equals 4. It contains two shaded chromosomes and two white chromosomes. There are two large chromosomes, one shaded and one white, and two small chromosomes, one shaded and one white. The large chromosomes have one arm that is slightly shorter than the other. The small chromosomes have two arms of equal sides. Four slightly smaller circles below the first circle are labeled gametes produced. From left to right, they contain the following chromosomes. Left-hand gamete: A large gray chromosome, a small gray chromosome, and a small white chromosome. Second gamete: A large gray chromosome and a small gray chromosome. Third gamete: A large

white chromosome and a small white chromosome. Fourth gamete: A large white chromosome.

Return to A figure shows the gametes produced from a parental cell with 2 italicized n end italics equals 4

Extended description for: A figure shows a chemical reaction in which water is added to a molecule to form two products

A molecule is depicted as H O bonded to a chain of three open circles with the right-hand circle bonded to H. An arrow shows that H 2 O is added to the bond between the second and

third white circles, numbered from left to right. An arrow points down and splits to show that two products are formed. The left-hand product resembles the reactant but has only two circles instead of three. The right-hand product is similar but has only one circle instead of three.

Return to A figure shows a chemical reaction in which water is added to a molecule to form two products

Extended description for: A figure compares gene expression with and without oxidative stress

The left-hand side of the figure is labeled no oxidative stress. Below the heading, a box labeled K e a p 1 has a horizontal line extending right to a short perpendicular line right before an oval labeled N f r 2. A horizontal double helix of D N A is depicted below. The right-hand side of the

figure is labeled oxidative stress. A vertical line extends down from the words oxidative stress to a short perpendicular line directly above the box labeled K e a p 1. A box at the upper right labeled italicized G p x 2 end italics has a line extending diagonally left to end at a short perpendicular line immediately before the words oxidative stress. There is a horizontal piece of D N A below with an oval labeled N r f 2 attached to its upper left side. Immediately to the right of the oval, a vertical line extends up from the D N A to a horizontal arrow pointing right to text reading, italicized G p x 2 end italics transcription, from which an arrow points to the box labeled

italicized G p x 2 end italics.

Return to A figure compares gene expression with and without oxidative stress

Extended description for: A figure shows four possible trophic relationships labeled a through d

Morris, et al., *Biology for the AP ® Course*, 1e, © 2022 BFW High School Publishers

Each of the parts of the figure shows a triangle with a wide base and vertex

at the top, and each is divided into four horizontal segments. Each segment is narrower than the segment below it due to the triangular shape.

Part a: An arrow labeled energy flow points upward along the side of the triangle toward its vertex. From bottom to top, the segments of the triangle are labeled rice, bacteria, italicized Chilomonas end italics, and italicized Paramecium end italics.

Part b: An arrow labeled energy flow points downward along the side of the triangle toward its base. From bottom to top, the segments of the triangle are labeled rice, bacteria, italicized

Chilomonas end italics, and italicized Paramecium end italics.

Part c: An arrow labeled energy flow points upward along the side of the triangle toward its vertex. From bottom to top, the segments of the triangle are labeled italicized Paramecium end italics, italicized Chilomonas end italics, bacteria, and rice.

Part d: An arrow labeled energy flow points downward along the side of the triangle toward its base. From bottom to top, the segments of the triangle are labeled italicized Paramecium end italics, italicized Chilomonas end italics, bacteria, and rice.

Return to A figure shows four possible trophic relationships labeled a through d

Extended description for: A phylogenetic tree shows the relationships between seven species labeled J through P

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The tree begins with a vertex at the left side. From this vertex, diagonal

lines extend to Species J at the upper right and Species P at the lower right. The diagonal line that ends at Species P has four branches. The first branch is near the start of the tree and splits at one-third of its length to form two lines with the upper line ending at Species K and the lower line ending at Species L. Near the midpoint of the line from the start of the tree to Species P, a line branches to Species M. Between the branch to Species M and the end of the line to Species P, there are two branches. The branch to Species N is first, just after the branch to Species M, and then there is a branch to Species O just before the line ends at Species P.

Return to A phylogenetic tree shows the relationships between seven species labeled J through P

Extended description for: A figure shows a pedigree for italicized Eleutherodactylus coqui end italics frogs

Morris, et al., *Biology for the AP ® Course,* 1e, © 2022 BFW High School Publishers

Male with stripes
Female with stripes
Male without stripes
Female without stripes

A key indicates that shaded squares represent males with stripes, shaded circles represent females with stripes, open squares represent males without stripes, and open circles represent females without stripes. Two pairings are depicted at the top, forming the first row of the pedigree and representing two sets of parents. At the upper left, an open square is connected by a horizontal line to a shaded circle. A line extends down from the center of this horizontal line to a horizontal line below that has vertical lines extending down from its left and right sides to offspring in row 2. The left-hand vertical line ends at a shaded circle, and the right-hand line ends at a shaded square. The shaded

circle is connected by a horizontal line to an open square to the left, and a vertical line extends down from this horizontal line to a horizontal line with vertical lines at each end with the left-hand vertical line extending to an open square and the right-hand line extending to a shaded circle, representing the next generation of offspring. The upper right pair in the top row consists of a shaded square and a shaded circle connected by a horizontal line with a vertical line extending down from it to a horizontal line with vertical lines extending from its left and right sides. The left-hand vertical line ends at a shaded circle, and the right-hand line ends at a shaded square, representing

the offspring. The shaded circle has a horizontal line connecting it to the shaded square produced by the pairing of the left-hand set of parents. This horizontal line has a vertical line extending down to a horizontal line with vertical lines extending down to the left and right with the left-hand line leading to a shaded circle and the right-hand line leading to an open circle, representing the offspring. Of the two offspring of the second set of parents at the right side of the top row, the shaded square is connected by a horizontal line to an open circle, and a vertical line extends down to a horizontal line with vertical lines extending down to the left and right. The left-hand line leads to an open

square, and the right-hand line leads to a shaded circle, representing the offspring.

Return to A figure shows a pedigree for italicized Eleutherodactylus coqui end italics frogs

Extended description for: A figure shows how chorismate can be used to produce tryptophan, phenylalanine, and tyrosine

Chorismate is depicted at the upper left with arrows pointing to its lower left and lower right. The arrow to the

lower left is labeled T r p 3 p and yields A N T H, from which a series of three arrows points down to a box labeled tryptophan. An arrow points from tryptophan to the arrow pointing from chorismate to the lower right, which is labeled A r o 7 p. The arrow pointing from chorisomate to the lower right yields P P A, from which arrows point to the lower left and right. The arrow pointing from P P A to the lower left is labeled P h a 2 p and yields P P Y, from which an arrow points down to a box labeled phenylalanine. The arrow pointing from P P A to the lower right is labeled T y r 1 p and yields H P P, from which an arrow points down to a box labeled tyrosine. A line runs

from tyrosine to end at a short perpendicular line just before A r o 7 p at the arrow pointing from chorismate to the lower right.

Return to A figure shows how chorismate can be used to produce tryptophan, phenylalanine, and tyrosine

Extended description for: A graph plots phenylalanine against tryptophan using a box-and-whisker plot

The horizontal axis is labeled supplemental tryptophan (micrograms per milliliter) and ranges from 0 to 150, in increments of

25. The vertical axis is labeled phenylalanine (micromoles). A vertical rectangle with error bars appears above each label on the vertical axis. These are described following their location on the horizontal axis. 0 on the horizontal axis: the rectangle extends from 40 to 85 with a dark horizontal line at 51, with errors bars extending above to 102 and below to 25. 25 on the horizontal axis: the rectangle extends from 60 to 105 with a dark horizontal line at 75, with error bars to 110 above and 50 below. 50 on the horizontal axis: the rectangle extends from 125 to 175 with a dark horizontal line at 150, with error bars to 190 above and 110. Below 100 on the horizontal axis:

the rectangle extends from 180 to 220 with a dark horizontal line at 200, with errors bars to 230 above and 170 below. 150 on the horizontal axis: the rectangle extends from 190 to 225 with a dark horizontal line at 206, with error bars extending to 245 above and 175 below. All data are approximate.

Return to A graph plots phenylalanine against tryptophan using a box-and-whisker plot

Extended description for: A graph compares the ability of two lineages of italicized Drosophila melanogaster end italics to defend themselves against parasitoid wasps over 8 generations

The horizontal axis is labeled generations and ranges from 0 to 8, in increments of 1. The vertical axis is labeled percentage of successful host defense and ranges from 0 to 80, in increments of 20. A key indicates that the curve with solid squares represents exposed to parasitoid wasps before breeding and the curve with open squares represents random individual chosen for breeding. The

curve for exposed wasps begins at (0, 5) and increases steadily before developing a zigzag pattern before ending at (8, 52). The points on the curve are as follows with error bars: (0, 5 plus or minus 2), (1, 16 plus or minus 2), (2, 22 plus or minus 3), (3, 37 plus or minus 5), (4, 43 plus or minus 5), (5, 56 plus or minus 3), (6, 53 plus or minus 3), (7, 60 plus or minus 3), and (8, 51 plus or minus 3). The curve for random individual chosen for breeding begins at (0.2, 4) and rises slightly, runs roughly horizontally, then decreases gradually until it ends at (8, 7). The points on the curve are as follows with error bars: (0.2, 4 plus or minus 1), (1, 7 plus or minus 2), (2, 7.5 plus or minus

2), (3, 8 plus or minus 2), (4, 9 plus or minus 2), (5, 10 plus or minus 2), (6, 8 plus or minus 2), (7, 7.5 plus or minus 2), and (8, 7 plus or minus 2). All data are approximate.

Return to A graph compares the ability of two lineages of italicized Drosophila melanogaster end italics to defend themselves against parasitoid wasps over 8 generations

Extended description for: A graph plots amount of italicized g a l 1 end italics m R N A transcripts and galactokinase proteins per cell by time and documents the effects of adding and removing galactose

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The horizontal axis is labeled time (minutes) and ranges from 0 to 300, in increments of 60. The left-hand vertical axis is labeled italic g a l 1 end italics transcripts per cell and ranges from 0 to 150, in increments of 25. The right-hand vertical axis is labeled galactokinase proteins per cell and ranges from 0 to 10 superscript 5, labeled on a logarithmic scale. A key indicates that a dashed line represents m R N A and a solid line represents protein. Arrows show that galactose is added at 60 minutes and removed at 200 minutes. The curve for galactose begins by running horizontally along the horizontal axis, then begins to rise with an increasing slope beginning at 60 minutes. It

forms a smooth, broad peak centered at (250, 125), then descends slightly to end at (310, 120). The curve for m R N A runs horizontally along the horizontal axis and then begins to rise at 60 minutes when galactose is added. It rises to a broad peak at 190 just below 10 superscript 4 end superscript, at the time galactose is removed, then descends almost vertically to meet the horizontal axis at 250 minutes before running right along the horizontal axis to end at (310, 0). All data are approximate.

Return to A graph plots amount of italicized g a l 1 end italics m R N A transcripts and galactokinase proteins per cell by time and documents the

effects of adding and removing galactose

Extended description for: A graph plots insect abundance per plant by sampling date to compare patterns in experimental gardens with different numbers of plant genotypes

The horizontal axis is labeled sampling date and ranges from May 30 to Aug 14, labeled in varying increments. The vertical axis is labeled insect abundance per plant and ranges from 0 to 10, in increments of 2. A key titled number of plant genotypes in experimental garden shows that gray represents 1, open circles represent 2, and filled circles represent 8. Error bars are depicted on the graph but overlap so that matching an exact error bar to a specific point is not always possible. The gray curve for one genotype begins at May 30 at 0 with no error bar, rises slightly by June 11 to 2 plus or minus 3 to 5, decreases by Jul 2 to just above 0 with an error bar of 7 to

10, rises by Jul 23 to 4.2 plus or minus 5, and decreases by Aug 14 to 3.3 plus or minus 5. The curve with open circles for 4 genotypes begins at May 30 at 0.1 plus or minus 8, remains the same at June 11, rises slightly by July 2 to 0.1 plus or minus 7 to 10, rises by Jul 23 to 7.8 plus or minus 4 or 5, and decreases by Aug 14 to 6.1 plus or minus 5. The curve with filled circles for 8 genotypes begins at May 30 at 0 with no error bars, increases by June 11 to 2 plus or minus 3 to 5, decreases by Jul 2 to 0 plus or minus 7 to 10, rises by Jul 23 to 7.8 plus or minus 4 or 5, and decreases by Aug 14 to 5.6 plus or minus 5. All data are approximate.

Return to A graph plots insect abundance per plant by sampling date to compare patterns in experimental gardens with different numbers of plant genotypes

Extended description for: A figure shows the structure and function of the electron transport chain used in the light reaction of photosynthesis

Morris, et al., Biology for the AP® Course, 1e, © 2022 BFW High School Publishers

A horizontal piece of membrane has structures embedded in it. The region above the membrane is labeled stroma, and the region below the

membrane is labeled lumen. There are six H plus in the lumen and two H plus in the stroma. From left to right, the structures are as follows: a vertical rectangle labeled P S Roman numeral 2 that crosses the entire membrane, a sphere near the top of the membrane, a narrow vertical rectangle that crosses the entire membrane, a sphere near the bottom of the membrane, a vertical rectangle labeled P S Roman numeral 1 that crosses the entire membrane, a small sphere near the top of the membrane just to the right of P S Roman numeral 1, an oval sphere just to the right of the sphere next to P S Roman numeral 1, a space with no structures in the membrane, and then a vertical

cylindrical structure that crosses the entire membrane and has a small cylindrical structure emerging from its top to meet a rounded portion of three vertical ovals and labeled A T P synthase. An arrow labeled light points into P S Roman numeral 2. Below and slightly to the left of P S Roman numeral 2, H 2 O is depicted with an arrow that branches to point to one-half O 2 plus 2 H plus in the lumen and to an arrow labeled e minus that runs up to point to a circle labeled e minus near the top of P S Roman numeral 2. Arrows point from this e minus to the sphere to the right at the top of the membrane, then to the narrow vertical rectangle, then to the sphere to the right at the bottom

of the membrane, then to P S Roman numeral 1. An arrow points from H plus in the stroma through the narrow vertical rectangle to H plus in the cytoplasm. An arrow labeled light points into P S Roman numeral 2. An arrow points up from the place that the arrow from the sphere to the left and the arrow from light meet to a circle labeled e minus near the top of P S Roman numeral 1. A series of arrows point from e minus in P S Roman numeral 1 to the adjacent sphere, then to the oval to its right that is met by a curved arrow in the stroma that begins at N A D P plus, meets this oval, and then curves away to indicate that N A D P H is formed. An arrow points from H plus in the

lumen through A T P synthase to H plus in the stroma. A curved arrow runs through this arrow to H plus, just above A T P synthase, from P subscript i end subscript plus A D P on the left to A T P on the right. A D P is depicted as a structure with protrusions to the upper left and right above a central portion that is attached to a chain of two spheres. A T P is similar except that it has a chain of three spheres.

Return to A figure shows the structure and function of the electron transport chain used in the light reaction of photosynthesis

Extended description for: A graph plots average height against average diameter to illustrate the relationship between these characteristics of Douglas fir trees

The horizontal axis is labeled average diameter (centimeter) and ranges

from 0 to 30, in increments of 5. The vertical axis is labeled average height (meter) and ranges from 0 to 20, in increments of 2. A diagonal line runs from (7, 6.1) to (27.5, 18). The following points are plotted on the graph: (7, 6.1), (12.5, 9.4), (17.5, 13), (24, 15.8), and (17.5, 17.9). All of the points are on or adjacent to the line except for the point at (17.5, 13), which is slightly above the line. All data are approximate.

Return to A graph plots average height against average diameter to illustrate the relationship between these characteristics of Douglas fir trees

Extended description for: A graph shows an example of how to plot points on a graph and look for a pattern

The horizontal axis is labeled time and ranges from 4 a. m. to 9 a. m., in increments of 1 hour. The vertical axis is labeled number of birds

singing and ranges from 0 to 20, in increments of 5. The data on the graph are as follows: (4, 6), (5, 10), (6, 17), (7, 14), (8, 14), and (9, 8). All data are approximate.

Return to A graph shows an example of how to plot points on a graph and look for a pattern

Extended description for: A graph shows how to set up an x y graph and label the axes

The horizontal axis is labeled time and ranges from 4 a. m. to 9 a. m., in increments of 1 hour. The vertical axis is labeled number of birds singing and ranges from 0 to 20, in

increments of 5.

Return to A graph shows how to set up an x y graph and label the axes

Extended description for: A graph plots average distance from nearest neighbor against elevation for fireweed flowers as an example of a histogram

The horizontal axis is labeled elevation (meters) and has five

categories, each accompanied by a bar. From left to right, the categories are 0 to 610, 610 to 1219, 1219 to 1829, 1829 to 2438, and 2438 to 3048. The vertical axis is labeled average distance from nearest neighbor (meters) and ranges from 0 to 4.0, in increments of 0.5. The data in the graph are as follows with elevation followed by average distance. Elevation 0 to 610, average distance 0.29; elevation 610 to 1219, average distance 0.46; elevation 1219 to 1829, average distance 1.1; elevation 1829 to 2438, average distance 2.8; and elevation 2438 to 3048, average distance 3.4. All data are approximate.

Return to A graph plots average distance from nearest neighbor against elevation for fireweed flowers as an example of a histogram

Extended description for: A graph illustrates how to produce a bar graph showing two characteristics for each of four wildflower species and using error bars of plus or minus 2 standard error

The horizontal axis is titled wildflower species and shows four species. From left to right, the species are beeblossom, false hellebore, fireweed, and silky lupine. There are two differently colored bars for each species, one representing maximum height in forest and the other representing maximum height in meadow. The vertical axis is labeled wildflower maximum height (centimeters) and ranges from 0 to 120, in increments of 20. Error bars are depicted as vertical lines that extend equal distances above and below the top of each bar before reaching a short perpendicular bar. The data in the graph are as follows. Beeblossom: maximum height in

forest, 20 with plus or minus 6.1, maximum height in meadow, 48 with plus or minus 8.7; False hellebore: maximum height in forest, 95 with plus or minus 10.8, maximum height in meadow, 110 with plus or minus 9.2; Fireweed: maximum height in forest, 79 with plus or minus 9.4, maximum height in meadow, 91 with plus or minus 14.6; Silky lupine: maximum height in forest, 32 with plus or minus 7.3, maximum height in meadow, 39 with plus or minus 4. All data are approximate.

Return to A graph illustrates how to produce a bar graph showing two characteristics for each of four wildflower species and using error

bars of plus or minus 2 standard error

Extended description for: A two-part graph shows histograms, plotting frequency of upper respiratory symptoms in part a and frequency of lower respiratory symptoms in part b

Part a is a histogram showing the frequency of upper respiratory symptoms. It has a horizontal axis

labeled upper respiratory symptoms that ranges from 0 to 15, in increments of 2. There are bars with heights to indicate the frequency for each of these values. The vertical axis is labeled frequency and ranges from 0 to 50, in increments of 5. The data in the graph are as follows with the number to the left of the column indicating respiratory symptoms followed by the frequency: (0, 4), (1, 2), (2, 9), (3, 14), (4, 23), (5, 24), (6, 26), (7, 45.5), (8, 38), (9, 14), (10, 12.5), (11, 10), (12, 4), (13, 7), and (14, 4).

Part b is a histogram showing the frequency of lower respiratory symptoms. It has a horizontal axis labeled lower respiratory symptoms

that ranges from 0 to 9, in increments of 2. There are bars with heights to indicate the frequency for each of these values. The vertical axis is labeled frequency and ranges from 0 to 50, in increments of 5. The data in the graph are as follows with the first number indicating respiratory symptoms followed by the frequency: (0, 7.5), (1, 14), (2, 42), (3, 50), (4, 24), (5, 26), (6, 22.5), (7, 14), and (8, 8). All data are approximate.

Return to A two-part graph shows histograms, plotting frequency of upper respiratory symptoms in part a and frequency of lower respiratory symptoms in part b

Extended description for: A graph plots average water temperature against month to illustrate how to use a line graph

The horizontal axis is labeled month and ranges from January through December, in increments of one

month. The vertical axis is labeled average temperature (degrees Celsius) and ranges from 16 to 26, in increments of 1. The points plotted on the graph are connected by a line. The data in the graph are as follows: (January, 19), (February, 18), (March, 18), (April, 19), (May, 19), (June, 21), (July, 23), (August, 25), (September, 25), (October, 24), (November, 22), and (December, 21). All data are approximate.

Return to A graph plots average water temperature against month to illustrate how to use a line graph

Extended description for: A graph shows how to use a dual y graph, which is a graph with two vertical axes

The horizontal axis is labeled year and ranges from 1900 to 2020, in increments of 20. The left-hand vertical axis is labeled atmospheric C

O subscript 2 (parts per million) and ranges from 280 to 420, in increments of 20. The right-hand vertical axis is labeled C O subscript 2 emissions (billions of tons) and ranges from 0 to 40, in increments of 5. Two sets of points are plotted on the graph, each with the points connected by lines to form a curve. The first curve representing atmospheric C O subscript 2 begins at (1900, 296) and ends at (2020, 413). It passes through the following points: (1900, 296), (1920, 304), (1940, 312), (1960, 319), (1980, 340), (2000, 370), and (2020, 413). The second curve representing C O subscript 2 emissions (billions of tons) begins at (1900, 2.1) and ends at (2020, 36.7). It passes through the

following points: (1900, 2.1), (1920, 3.7), (1940, 5.0), (1960, 9.6), (1980, 19.0), (2000, 25.0), and (2020, 35.7). All data are approximate.

Return to A graph shows how to use a dual y graph, which is a graph with two vertical axes

Extended description for: A graph plots number of bacteria against temperature to produce a graph that can be compared to a log scale graph presenting the same data

The horizontal axis is labeled

temperature (degrees Celsius) and ranges from 0 to 25, in increments of 5. The vertical axis is labeled number of bacteria and ranges from 0 to 90,000, in increments of 10,000 beginning with 10,000. The line consists of a series of six points connected by lines. The curve begins at (0, 0) and ends at (25, 85,000). The first part of the graph appears horizontal, then the curve begins to increase after 10 on the horizontal axis, increases at a steeper angle from 10 to 15 on the horizontal axis, then increases even more steeply from 20 to 25 on the horizontal axis. The points on the graph are as follows: (0, 5), (5, 40), (10, 310), (15, 2500), (20, 15,000), and (25, 85,000). However, the

values from 5 to 10 are indistinguishable on the graph as they are so close to 0 with such a large vertical scale. All data are approximate.

Return to A graph plots number of bacteria against temperature to produce a graph that can be compared to a log scale graph presenting the same data

Extended description for: A graph plots number of bacteria (log scale) against temperature to indicate how log scales work

The horizontal axis is labeled temperature (degrees Celsius) and ranges from 0 to 25, in increments of

5. The vertical axis is labeled number of bacteria (log scale) and ranges from 1 to 100,000, labeled on a logarithmic scale. On the vertical axis, the labeled units of the logarithmic scale are as follows: 1; 10; 100; 1000; 10,000; and 100,000. To illustrate how the vertical axis is affected, horizontal lines are used to divide up each increment on the vertical scale. There are 10 horizontal lines between each labeled increment and the lines become progressively closer together from the bottom to the top of each increment, then start again with wider spacing at the start of the next increment. A diagonal line extends from (0, 4) to (25, 85,000). Points plotted on the line are as

follows: (0, 4), (5, 45), (10, 350), (15, 3000), (16, 19,000), and (25, 85,000). All data are approximate.

Return to A graph plots number of bacteria (log scale) against temperature to indicate how log scales work

Extended description for: An example of a pie chart shows percentages of five tree species in a plot of land

Morris, et al., *Biology for the AP® Course*, 1e, © 2022 BFW High School Publishers

The pie chart has five wedges that are

each labeled. Clockwise from the top, the data are as follows: pine 36 percent, elm 14 percent, oak 23 percent, walnut 9 percent, and maple 19 percent.

Return to An example of a pie chart shows percentages of five tree species in a plot of land

Extended description for: An example pie chart without percentages listed shows greenhouse emissions from various sources

The pie chart contains six wedges that

are each labeled. Clockwise from the top, the sections are electricity and heat production; agriculture, forestry, and other land use; buildings; transportation; industry; and other energy. Electricity and heat production takes up most of the upper right quarter of the pie chart, and agriculture, forestry, and other land use takes up almost as much of the lower right quarter. The wedge for buildings is relatively small and extends from just before the six o'clock position to before the seven o'clock position. Transportation is next and extends almost to the nine o'clock position. The industry wedge is slightly larger than the transportation wedge and extends to

just past the eleven o'clock position. The other energy wedge is the smallest and extends from industry to electricity and heat production. All data are approximate.

Return to An example pie chart without percentages listed shows greenhouse emissions from various sources

Extended description for: A graph shows an example of a box and whisker graph

The vertical axis ranges from 0 to 40, in increments of 5. A vertical bar extends from 14 to 29 with a dark horizontal line across its center with an arrow pointing right to indicate

that it represents the median 23. Brackets enclosing the box are accompanied by text reading, contains 50 percent of the data. An arrow pointing right from the top of the box is accompanied by text reading, 29.5. An arrow pointing right from the bottom of the box is accompanied by text reading, 14. Short vertical lines extend up and down from the vertical bar. These lines are each the same size and each end in a short vertical bar. A bracket from the top of the box to the perpendicular line above is accompanied by text reading contains 25 percent of the data, and an arrow points right from the top perpendicular line to text reading,

maximum value of data 35. A bracket from the bottom of the box to the perpendicular line below is accompanied by text reading contains 25 percent of the data and an arrow points right from the bottom perpendicular line to text reading, minimum value of data 10.

Return to A graph shows an example of a box and whisker graph

Extended description for: A graph plots richness against habitat to illustrate the use of a box and whisker graph to show the distribution of rotifer species richness in different habitats

The horizontal axis is labeled habitat.

From left to right, the habitats are labeled A, B, C, D, E, and F. There is a box-and-whisker plot above each letter. The vertical axis is labeled richness and ranges from 1 to 7, in increments of 1. The data in the graph are as follows. Habitat A: A vertical box has a dark vertical bar at 2, extends from 1 to 2.5, and has an error bar extending upward to 4. Habitat B: A vertical box has a dark vertical bar at 3, extends from 2.5 to 4, and has error bars to 6 above and to 2 below. Habitat C: A vertical box extends from 5 to 6 and has error bars extending up to 7 and down to 4. Habitat D: A vertical box has a dark vertical bar at 3, extends from 2 to 4, and has error bars extending up to 5

and down to 1. Habitat E: A vertical box has a dark vertical bar at 3, extends from 2.5 to 3.5, and has error bars extending up to 5 and down to 2. Habitat F: A vertical box extends from 3 to 4, and has error bars extending up to 5 and down to 2, and has an open circle at 6.1 above. All data are approximate.

Return to A graph plots richness against habitat to illustrate the use of a box and whisker graph to show the distribution of rotifer species richness in different habitats

Extended description for: A graph plots number of COVID-19 cases against date to illustrate an example of an area graph

The horizontal axis is labeled Month/year and ranges from 03/20 to 06/21, in increments of one month. The vertical axis is labeled number of

COVID-19 cases (thousands) and ranges from 0 to 400, in increments of 50. A key lists nine cities and shows which colors represent them. The graph shows layers of different colors that correspond to the different cities. The data in the graph are as follows. Napa: The color is barely visible until 12/20, then rises slightly to peak at 06/21 and 5. Marin: The curve begins at 07/20 at about a height of 7 and increases only slightly before ending at 06/21 at a height of 10. Sonoma: The curve begins between 6/20 and 7/20 as a thin sliver that gradually increases in width to end at 6/21 with a height of 25. Solano: The curve begins at 05/20 and gradually increases until 02/21, when it

increases more dramatically to end at 06/21 with a height of 25. San Francisco: The curve begins at 05/20 and gradually increases until 02/21, when it increases more dramatically to end at a height of 50. San Mateo: The curve begins at 04/20 and increases gradually to a height of 20 in 02/21, then increases more dramatically to end at a height of 50. Contra Costa: The curve begins at 04/20 and increases gradually but more rapidly than any of the previous cities. It increases dramatically at 2/21 from 25 to end at 55. Alameda: The curve begins at 04/20 and rises gradually until 02 /21, when it increases dramatically to end at 80. Santa Clara begins at 04/20 and

increases very gradually through 07/20, then increases more rapidly in a similar pattern to Alameda to reach 25 before expanding rapidly by 02/21 to end at a height of 100. All data are approximate.

Return to A graph plots number of COVID-19 cases against date to illustrate an example of an area graph

Extended description for: A graph plots pace of aging against biological aging to illustrate a scatter plot graph

The horizontal axis is labeled biological age and ranges from below 30 to above 50, in increments of 5. The vertical axis is labeled pace of

aging and ranges from below 0.75 to 1.50, in increments of 0.25. A diagonal line begins at (32, 07) and ends at (48, 1.40). There are many dots above and below the lower two-thirds of the line with two dots to the upper right of the upper end of the line. The dots roughly follow the path of the line, even though they are spread around it. All data are approximate.

The periodic table shows seven rows and eighteen columns (or groups) with elements in each group identified from 1 to 8. The symbol and

atomic number are given. In the first group from the left the elements of group 1 A are Hydrogen, H, 1; Lithium, L i, 3; Sodium, N a, 11; Potassium, K, 19; Rubidium, R b, 37; Cesium, C s, 55; and Francium, F r, 87. In the second group 2 A the elements are Beryllium, B e, 4; Magnesium, M g, 12; Calcium, C a, 20; Strontium, S r, 38; Barium, B a, 56; and Radium, R a, 88. In the third group 3 A the elements are Boron, B, 5; Aluminum, A l, 13; Gallium, G a, 31; Indium, I n, 49; Thallium, T l, 81; and Nihonium, N h, 113. In the fourth group 4 A the elements are Carbon, C, 6; Silicon, S I, 14; Germanium, G e, 32; Tin, S n, 50; Lead, P b, 82; and Flerovium, F l, 114. In the fifth group

5 A the elements are Nitrogen, N, 7; Phosphorous, P, 15; Arsenic, A s, 33; Antimony, S b, 51; Bismuth, B i, 83; and Moscovium, M c, 115. In the sixth group 6 A the elements are Oxygen, O, 8; Sulfur, S, 16; Selenium, S e, 34; Tellurium, T e, 52; Polonium, P o, 84; and Livermorium, L v, 116. In the seventh group 7 A the elements are Fluorine, F, 9; 19.00, Chlorine, C l, 17; Bromine, B r, 35; Iodine, I, 53; Astatine, A t, 85; and Tennessine, T s, 117. In the eight group 8 A the elements are Helium, H e, 2; Neon, N e, 10; Argon, A r, 18; Krypton, K r, 36; Xenon, X e, 54; Radon, R n, 86; and Oganesson, O g, 118. There are some more elements between column 2 and column 3. They are in the fourth,

fifth, sixth, seventh, and eighth row. The column from left to right are 3 B, 4 B, 5 B, 6 B, 7 B, 8 B, 9 B, 10 B, 1 B, and 2 B. The elements in row four are Scandium, S c, 21; Titanium, T i, 22; Vanadium, V, 23; Chromium, C r, 24; Manganese, M n, 25; Iron, F e, 26; Cobalt, C o, 27; Nickel, N i, 28; Copper, C u, 29; and Zinc, Z n, 30. The elements in row five are Yttrium, Y, 39; Zirconium, Z r, 40; Niobium, N b, 41; Molybdenum, M o, 42; Technetium, T c, 43; Ruthenium, R u, 44; Rhodium, R h, 45; Palladium, P d, 46; and Silver, A g, 47; and Cadmium, C d, 48. The elements in row six begins from column 2 till column 5 and they are Caesium, C s, 55; Barium, B a, 56; Hafnium, H f, 72;

Tantalum, T a, 73; Tungsten, W, 74; Rhenium, R e, 75; Osmium, O s,76; Iridium, I r, 77; Platinum, P t, 78; Gold, A u, 79; Mercury, Hg, 80; Thallium, T l; 81, Lead, P b, 82; and Bismuth, B i, 83. The element in row 8 and column 4 is Thorium, T h, 900. The element in row 8 and column 6 is uranium, U, 92. The lanthanides are elements from atomic number 57 to 71. They are Lanthanum, L a, 57; Cerium, C e, 58; Praseodymium, P r, 59; Neodymium, N d, 60; Promethium, P m, 61; Samarium, S m, 62; Europium, E u, 63; Gadolinium, G d, 64; Terbium, T b, 65; Dysprosium, D y, 66; Holmium, H o, 67; Erbium, E r, 68; Thulium, T m, 69; Ytterbium, Y b, 70; and Lutetium, L u,

71. The actinides are elements from atomic number 89 to 103. They are Actinium, A c, 89; Thorium, T h, 90; Protactinium, P a, 91; Uranium, U, 92; Neptunium, N p, 93; Plutonium, P u, 94; Americium, A m, 95; Curium, C m, 96; Berkelium, B k, 97; Californium, C f, 98; Einsteinium, E s, 99; Fermium, F m, 100; Mendelevium, M d, 101; Nobelium, N o, 102; and Lawrencium, L r, 103.

The elements found in human cells in various categories are: High: Hydrogen, Carbon, Nitrogen, Phosphorous, and Oxygen; Low: Sodium, Magnesium, Potassium, Calcium, Sulfur, and Chlorine; Trace: Vanadium, Chromium, Manganese,

Iron, Cobalt, Nickel, Copper, Zinc, Molybdenum, Fluorine, Iodine, and Selenium. All other elements are rare or not present in human cells.

You are about to embark on a dramatic learning adventure. The subject is no less than how all of life works. You will emerge from this course in a better position to understand issues related to biological sciences that affect you as a person and as a citizen.

—Jim Morris, Dom Castignetti, John Lepri, Rick Relyea

Your Journey Has Begun.

The Canada lynx (*Lynx canadensis*), with its piercing green eyes that seem to be looking directly at you, is a predator whose form and function has been shaped over generations. It has also shaped that of its prey—the snowshoe hare (*Lepus americanus*). **How is that so?** You will soon find out. Welcome to ***Biology for the AP® Course***, where we invite you to ask and answer questions about how life works!

The AP® Biology course is a journey that is challenging, rewarding, and fun. This program will guide you every step of the way on your path to success in the course and on the exam. On this journey you will explore critical concepts in biology with the help of AP® Biology Science Practices, Big Ideas, and essential statistical and data analysis skills. Stunning visuals, helpful tutorials, and essential resources make learning an enjoyable and rewarding experience.

Built from the ground up for the AP® Biology course, *Biology for the AP® Course* is a program designed for you:

- Aligns to the organization and scope of the AP® Biology Course and Exam Description (CED) with thorough coverage of in-scope content, allowing more space for patient explanations and extra AP® practice.
- Presents coverage in brief modules for student-friendly pacing and accessible reading.
- Provides detailed in-text tutorials, instruction, and review, as well as practice with all required data analysis and statistical testing tools and techniques.
- Contains AP® Practice Questions at the end of each module and unit, plus a full Cumulative AP® Practice Exam at the end of the book.
- Focuses on the practice of science and AP® Science Practices.
- Written by a team of committed biology educators, AP® Biology teachers, and content experts.

Complete your journey with our BFW digital support that includes accessible and interactive features, an industry leading e-book, videos, online homework with targeted feedback, and more!

Let's begin! **bfwpub.com/Morris**

Note to the teacher: This program supports your instruction of the AP® Biology curriculum with superior, one-of-a-kind resources, including an indispensable Teacher's Edition written by Paula Phillips, James Smanik, and Gordon Uno. Please contact your local BFW rep for information on this and other AP® Biology course materials.
